
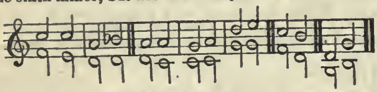
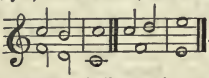
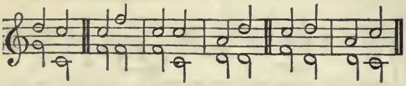
. From the fifth to either sixth is best by oblique motion; but it is allowed by similar motion if one part move a single degree: it is also allowed ascending, but not descending, to go by leap from the fifth to the sixth minor, but not to the major.



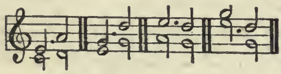
In passing from the fifth to the octave through a sixth, the sixth must be major, never minor; and it must be by contrary motion,



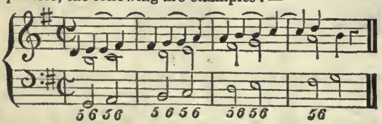
. An octave after a fifth by leap in similar motion must be avoided. By oblique and contrary motion, it is good and allowable by similar motion, one part moving a single degree, as follows:—

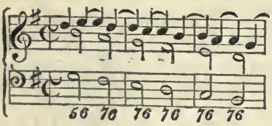


When a third or a sixth moves to a fifth in similar motion, there is said to be a *hidden fifth* in the passage. The reader will, in the following example, see by the dots where these lie.

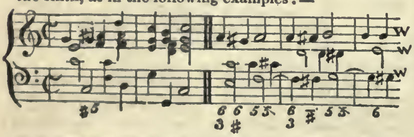


In a regular ascent, it is common for a fifth to be succeeded by a sixth, as in a descent it is for the seventh to be succeeded by a sixth. Of both these, which are termed *sequences*, the following are examples:—



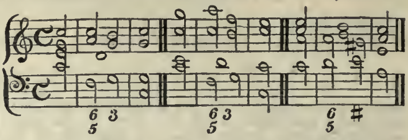


The chord of the extreme sharp fifth, which consists of two major thirds placed above each other, is generally preceded and succeeded by a common chord, or that of the sixth, as in the following examples:—

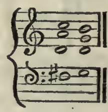


It is here seen that the extreme sharp fifth to the bass, whether it be in the middle or at the top of the chord, always rises to the resolution. It is called a *transient chord*.

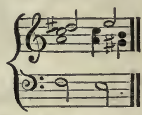
The sixth, by inversion, becomes a third; and it often happens that the bass which accompanies sixths will harmonize equally well with thirds. When accompanied with the fifth, the fifth is treated as a discord; which we will illustrate by two or three instances.



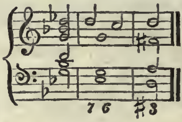
Some have given the name of the *great sixth* to this chord when the sixth is major and the fifth perfect. If the fifth is imperfect and the sixth minor, it is called the *chord of the false fifth*. It will be seen above that the chord of the great sixth is used on bass notes which ascend a tone to the perfect chord, and that of the false fifth to those which ascend a semitone,



. The species of this chord chiefly used in minor keys consists of a perfect fifth, an extreme sharp sixth, and major third; and the bass of it generally descends,



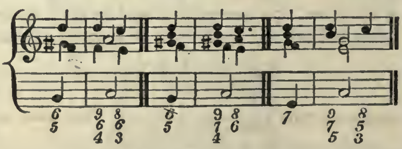
The minor seventh accompanied with a third major and perfect fifth is one of the most agreeable of the discords; it should be heard in the chord which precedes it when used with a minor third and perfect fifth,



. By raising the lower note of a minor seventh a minor semitone, the chord of the diminished or extreme flat seventh, also called the *equivocal chord*, is produced,

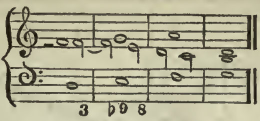
Minor 7th. Diminished 7th.

. This is called the equivocal chord, from the uncertainty of the key note into which it may lead. The preparation of a major seventh is a third, a fifth, a sixth, or an eighth; its resolution is a third, a sixth, and a fifth from the concords in which it is prepared. The ninth major consists of a whole tone, and the minor ninth a semitone major above the octave. The major ninth is prepared by a third, a fifth, and occasionally by a sixth, never by an eighth; and is resolved by a third, a sixth, or an eighth from each of the concords in which it is prepared. When the ninth is used in four parts, the third and fifth must be taken with it. Besides the above resolutions of the ninth, it may be resolved by the fifth if the bass rise a fourth or fall a fifth when the upper part falls one degree for its resolution. It must be accompanied at the resolution by an eighth, if the piece be in four parts. We subjoin a few examples:—



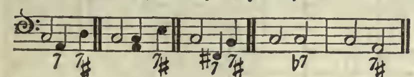
The minor ninth is prepared in the third only, and resolved in the eighth if the bass hold on till the resolution is made;

but it is resolved in the third if the bass descend a third on the resolution,

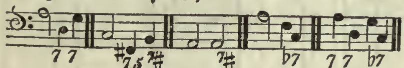


The ninth may have other discords mixed with it, as the fourth; in which case the fourth must be prepared and resolved as a discord. The seventh may be also mixed with it; in which case the seventh must be also separately prepared and resolved.

We have before defined the word *modulation:* our intention here is to add a few observations on the mode in which it is accomplished, premising that the laws of modulation are dependent on those of harmony. If you desire to keep in the key, you are to use all the sounds of the scale as much as possible, uniting them in good melody, and dwelling chiefly on those which carry the essential chords; that is, the chords of the seventh and key notes will be frequently wanted varied so as to avoid monotony. You must take cadences or pauses on these two chords only, or at furthest on that of the fourth of the key. You are never to alter the scale, because the introduction of a flat or a sharp not belonging to it indicates that the key is abandoned. To modulate into other keys formal cadences are not required; if they are, they are usually made at the end or in the middle of a piece. We subjoin the methods for passing from one key to another, which are five in number for the major and four for the minor keys; and these alone can be considered legitimate, unless through the medium of enharmonic modulation: leaving the major key of C,



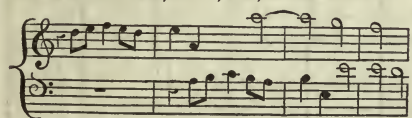
leaving the minor key of A,



Our limits prevent extending this part of the subject to greater length: those who would learn more on this point are recommended to *Frike's Guide to Harmony*, Lond. 1793.

A *fugue* consists in the repetition of a melody in the different parts at different intervals of time, each repeating, according to certain rules, what the preceding one has performed; the part which leads being called the *guide*, and that which repeats the *answer*. The answer is conducted by the same intervals as the guide.

Imitation differs from fugue, says Brossard, because in the former the repetition must be a second, third, sixth, seventh, or ninth, or indeed any interval above or below the first voice or guide; whereas in fugue the repetition must be in the unison, fourth, fifth, or octave: —



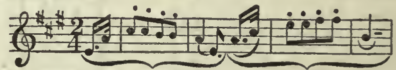
The principal rules in writing fugues are — First, to prefer the key note and its fifth before any other for the first and last notes of the fugue; in which case the melody is to be contained within the octave to the key. Second, if one part begin or end with the key note, the other begins and ends with the fifth, taking care that the different relative intervals between the notes be regularly preserved. Thirdly, as in diatonic progression either ascending or descending from the key note to its fifth, and the converse, there is one note difference, you are at liberty to make one of those two notes in conjoint degree of that progression that contains the greater number to agree with the progression which is unavoidably used, wherein there is one note less, and that in the middle of the melody. These are the leading rules of the fugue.

The *canon* is a species of fugue, which may be infinitely repeated; it is taken up at the fifth, and at the ourth. When this is done, the whole of the melody must be arranged, and accidental sharps and flats added to those notes where the use of the natural degrees would prevent the air from being exactly similar; whence its difficulty. The well-known canon of *Non Nobis Domine* is a fine specimen of canon composition.

Rhythm, in music, is the accommodation of the long and short notes to the syllables to which the music is set in such a manner as to separate the words properly, and to make the accented syllables of each word so conspicuous that what is sung may be clearly comprehended. In instrumental music, it is the adaptation of the expression to the sentiment. It is mostly used to signify the duration of several sounds heard in succession, whether musical by voices and instruments, or without inflexion of tone, as by the beating of a drum, &c. Here we nave only to speak of that which is connected with musical melody. Rhythm depends on *accent* principally, the *musical phrase*, *section*, and *period*. Of accent we have before spoken at nearly the beginning of this article, and we do not think it necessary to add to it in this place, further than to state that in the beating of time by the hand or foot, as there mentioned, the elevation of the hand is called by the technical name *arsis*, a Greek word signifying a lifting up; and the depression of it by the name *thesis*, signifying the action of laying down expressions, — which are also applicable in another sense, as, for instance, when a point or passage is inverted or turned, that is, rises in one part and falls in another, or the converse, it is said to move *per arsin et thesin*. Emphasis is frequently obtained for particular expressions by throwing the accent on the weak part of the measure, or by the different grouping of the quavers, semiquavers, &c., and also by the mark of emphasis, RF (signifying rinforzando), placed over a note where the composer is desirous of marking the weak part of a measure with more than its share of importance. Of this the following passage from a favourite symphony of Haydn is an example —

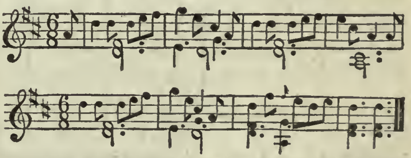
(Emphasis.)

on the note marked with a dash over it. Dr. Callcott thus distinguishes between accent and emphasis: — "Accent always requires pressure (on a pianoforte) immediately after the note is struck, and emphasis requires force at the very time of striking the note." A phrase is a short melody, usually formed of two measures in simple time, though with the ancient writers it is often contained within the bar. Of the common phrase the following is an example: —



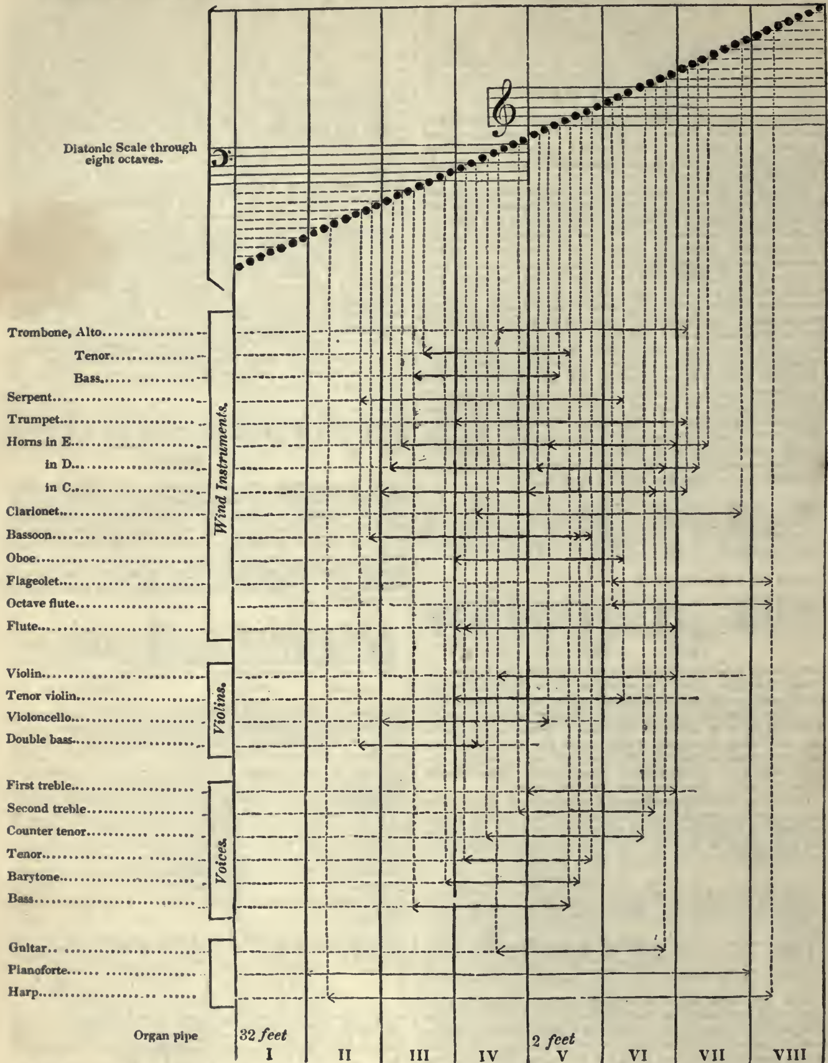
Andante. Phrase. Phrase.

Phrases in melody are formed by air; in harmony they are formed by sequences of chords and discords terminating with a cadence, which is more or less perfect as the passage is more or less finished. The well weaving together of the phrases whereof a strain is composed, so that their proportions may be symmetrical and form a beautiful whole, is one of the tests of a fine composer. Though musical punctuation, unlike that in writing, is without visible characters to mark the ends of phrases, and the periods whereof phrases are composed, yet such division does actually exist; and as an example of punctuation will better than words assist the reader in understanding it, we present to his notice the following well-known passage from the opera of *Don Giovanni*, by Mozart: —



In the four distinct parts into which this melody is divided three of them belong to the chord of the dominant or fifth of the key; and the other, which is the last, to the tonic or key note. The seventh of the dominant is upon the three first parts; but to avoid monotony, and yet to punctuate the first part, he has only got the A in the bass at the end of the second part. In the other two he has a pedal point (or holding on of the bass) of the key note, on which the chord of the seventh of the dominant is struck. A passage consisting of two regular phrases, the last ending with a cadence, is called a *section;* and one or more of these sections constitutes a *period*. When a period or more than one is terminated by a double bar, the whole is called a *strain*. We close this article with a synoptical view of the different pitches of the instruments of an orchestra, and of the human voice, from Choron's celebrated work, to which our acknowledgments are due; as well as to *Callcott's Musical Grammar;* the admirable art. "Music," by Momigny, in the *Encyc. Methodique;* and to *Shield's Introduction to Harmony*.

SYNOPTICAL VIEW of the different Pitches of the Instruments of an Orchestra, and of the Human Voice.



MU'SICAL GLASSES. A musical instrument consisting of a number of glass goblets, resembling finger glasses, which are tuned by filling them more or less with water, and played upon with the end of a finger damped. There are few persons at a dinner table who have not tried their skill in producing the sound which the vibration of a finger glass will yield in the way above described. The less the quantity of water in glasses of similar forms and equal capacity, the lower will be the tone of the scale; hence the facility of forming a complete scale by the quantity of water contained in each.

The skill, or rather knack, of operating upon the sets of glasses for the production of melodies and harmonies, is that of procuring instantly the required vibration by a gentle and rapid action of the finger upon their edges, and so quickly from one to another as to be able to introduce harmonies to the sounds of the air or melody before the vibrations of its glasses have ceased. A touch of the finger on the edge of a glass puts of course a stop to its vibration, and thus prevents confusion.

MUSK. A peculiar concrete substance, the produce of the *Moschus moschiferus*, or musk deer, an animal which inhabits the mountains of eastern Asia. Behind the navel is a bag, which in the adult animal is filled with musk. These bags are imported from China, Bengal, and Russia. Musk is originally a viscid fluid, but dries into a brown pulverulent substance, of a strong, peculiar, and highly diffusible odour. Its chief use is as a perfume: it has been employed in medicine as a stimulant antispasmodic, but much difference of opinion exists as to its efficacy; and its high price, and extreme liability to adulteration, are circumstances against its use.

MUSKAT. A rich sweet wine made in the south of France of over-ripe muscadine grapes.

MUSK DEER. (*Moschus moschiferus*, Linn.) The type of a distinct genus of Ruminants, with canine teeth and without horns. This species is especially remarkable for the large preputial glandular pouch which secretes the well-known substance called musk.

MUSKET. (Fr. mousquet.) The fire-arm used by the regiments of the line. (*See* GUN.) A great number of very curious ones, of various dates and countries, from

the earliest period of their use, may be seen in the repository of the Royal Artillery at Woolwich.

MU'SKETOON. A species of musket, shorter, but thicker and wider in the bore, than the ordinary musket. The musketoon, or *mousquetoon*, was of French invention, and is described by De Gaya, in 1688 (*Traité des Armes*), as differing from the carabine in being furnished with a fire-lock instead of a wheel-lock.

MU'SLIN. A fine thin kind of cotton cloth with a downy nap on the surface. The name is derived from the town Mosul, in Asia, where it was originally manufactured. The first muslin was imported from India into England in 1670; and twenty years afterwards it was manufactured in considerable quantities both in France and England. Muslins are now manufactured in immense quantities at Manchester and Glasgow, in France, Germany, and Switzerland, of a fineness and durability that rival those of India, at the same time that they are considerably cheaper. The fineness of some Indian muslins is such that when laid on grass upon which a little dew has fallen, they are scarcely visible. See COTTON.

MUSO'PHAGA. (Gr. *μουσα*, the generic name of the banana, and *φαγω*, *I eat.*) A genus of Scansorial birds, characterized by the base of the beak forming a disk which partly covers the forehead. The species of this genus are called "plantain eaters," because their principal food is the fruit of the banana.

MUSQUI'TO. The American name for the species of gnat (*Culex*). They abound in damp situations, both in the warmer climates and during the summer months in high northern latitudes. They pierce the skin with a lancetted proboscis, and discharge a venomous liquor into the wound; they can only be guarded against at night by enclosing the bed with a musquito curtain. The Laplanders drive them away by fire, and by coating the naked parts of the body with grease.

MUSSEL. *See* MYTILUS.

MU'SSITE. A pale green mineral from Mussa in Piedmont; it is a variety of *augite*.

MU'SSULMAN. The general appellation for all who embrace the faith of Mohammed. The term signifies "resigned to God;" and is the dual number of the singular *moslem*, of which *muslimim* is the plural. The appellation is said to have been first given to the Saracens.

MUST. The expressed juice of the grape before its conversion into wine by the process of fermentation.

MU'STARD. (Fr. moutarde.) The seed of the *Sinapis alba* and *nigra*, ground into powder, and freed from the husks: it is the well-known condiment of the shops, or at least a part of it; for, in order to reduce the strength of the pure mustard, there is generally a considerable quantity of wheaten flour added. Brown mustard should be the flour of *Sinapis nigra* exclusively, which is much more pungent than the other. A dessert spoonful of coarsely powdered mustard-seed, taken in a glass of water, generally operates as an emetic; it is also aperient. A mustard poultice, or *sinapism*, is sometimes a useful stimulant.

MUSTE'LA. (Lat. mustela, *a weasel.*) The generic name under which Linnæus comprehended the Vermine or Vermiform quadrupeds of Ray, or the carnivorous Mammalia, which are distinguished by the length and slenderness of their bodies, and are thus enabled to wind, like worms, into very small crevices and openings, whither they easily follow the little animals that serve them for food. The otters, skunks, polecats, and weasels were included in this genus, and still constitute the natural family *Mustelidæ;* and the genus *Mustela* is now restricted to the true weasels, which differ from the polecats in having an additional false molar above and below, and in the existence of a small internal tubercle on the lower "carnassial" or sectorial tooth; two characters which, Cuvier observes, somewhat diminish the cruelty of their nature.

MUSTER-ROLL. A specific list of the officers and men in every regiment, troop, or company, made out by the adjutant, and delivered to the inspecting field officer or paymaster, &c., by which they are paid, and their strength and condition known.

MUTE. In Grammar, a vowel (or consonant) is said to be mute when written but not pronounced; as the vowel *e* at the end of many English words, in some of which it effects a change in the pronunciation of the preceding vowel, as in *wife, life, place*, &c., rendering it long; in others it has no effect, as after a diphthong—*house, pronounce*. In old English, the mute *e* was very generally added at the end of words, especially nouns; and in versification the *e* often ceased to be mute, as is constantly the case in the poems of Chaucer.

MUTE, in Law, is said of a person who refuses to plead to an indictment for felony, &c. By stat. 12 Geo. 3. c. 20. such a person is to be considered as pleading guilty, and to be punished as upon conviction; but formerly a plea was extorted from him by the inhuman and disgusting process *peine forte et dure*, which see.

MUTE. A dumb officer of the Seraglio, whose duty it is to act as executioner of persons of exalted rank who have incurred the grand seignior's displeasure. The term mute is also applied to persons employed by undertakers to stand before the door of a house in which there is a corpse for a short time previously to the funeral.

MUTI'CA. (Lat. muticus, *maimed.*) A name applied by Linnæus to the third of his primary divisions of Mammalia, including the whale tribe, as being maimed, or deprived of the hinder pair of extremities; also given by Storr to an order of quadrupeds comprehending those which want either a certain kind of teeth, or are wholly edentulous.

MU'TINY, in Law, is the offence, in a person under military or naval authority, of resisting or refusing obedience to that authority. The Mutiny Act is a statute annually passed since the reign of William and Mary (April, 1689), by which the crown is vested with power to form articles of war, and to constitute military courts martial. *See* COURTS MARTIAL.

MUTULE. *See* MODILLION.

MU'ZARAB. Christians living under the government of the Moors in Spain; so called, it is said, from an Arabic word signifying imitators or followers of the Arabs. The denomination is now chiefly remembered in consequence of the celebrated disputes between the supporters of the Muzarabic liturgy, which was preserved by the Christians of Spain during their subjection to the Mahometans, and those of the Roman, introduced by the see of Rome about the 10th century. During the following age this dispute was warmly carried on, and well-known legendary tales of miracles operated in favour of the ancient ritual were long current in Spain. It was, however, gradually superseded by the Catholic. It is said that mass is still celebrated according to the Muzarabic ritual in one chapel at Toledo. A brief but excellent account of the different phases of the Muzarabic controversy is to be found in the *Dict. de la Conversation*. See also the *Penny Cyclopædia*, and the authorities there referred to.

MU'ZZLE LASHING. The lashing by which the muzzle of a gun in a ship is secured to the upper part of the port.

MY'A. (Gr. *μυων*, *a muscle.*) A name applied by Linnæus to a genus of the *Vermes testacea*, including those having a bivalve shell, characterized by a hinge with broad, thick, and strong teeth, seldom more than one, and not inserted into the opposite valve; shell generally gaping at one end. The Mollusks thus characterized form the first family (*Myacea*) of the tribe *Inclusa*, among the Acephalous Testacea of Cuvier. They have been subdivided into the genera *Mya* proper, *Lutraria*, Lam, *Anatina*, Lam., *Solemya*, Lam., *Glycimeris*, Lam., *Panopæa*, Lam., *Pandora*, Lam. The true *Myæ* include that species of the genus *Unio*, Brug., which is celebrated by Tacitus for producing pearls, and which is indigenous in some of the rivers of Scotland and England.

MYCE'LIA. (Gr. *μυκης*, *a fungus.*) The young flocculent filaments of fungi.

MYDRI'ASIS. (Gr.) A paralytic affection of the iris of the eye.

MY'ELENCE'PHALA. (Gr. *μυελος*, *marrow*, and *εγκεφαλον*, *brain.*) The name indicative of the condition of the nervous system of the primary division of animals, comprehending those which have a brain and spinal chord: it is synonymous with *Vertebrata*.

MY'ELONEU'RA. (Gr. *μυελος*, *marrow*, and *νευρον*, *nerve.*) A name given by Rudolphi to a group of animals corresponding to the Articulata of Cuvier, viz. Crustacea, Insects, and Anellides, which have a gangliated nervous system, forming a chord considered to be analogous to the spinal marrow of Vertebrates.

MY'LO. (Gr. *μυλη*, *a grinder tooth.*) Names compounded of this word are applied to certain muscles attached near the grinder teeth, as *mylohyoideus*, *mylopharyngeus*, &c.

MYO'LOGY. (Gr. *μυων*, *a muscle; λογος*, *a discourse.*) The doctrine of the muscles. In the Fine Arts, the term is applied to a description of the muscles of animals.

MY'OPS. (Gr. *μυωψ*; from *μυω*, *I wink*, and *ωψ*, *the eye.*) A person who is purblind or near-sighted. This defect usually arises from too great convexity of the cornea causing the rays to come to a focus before they arrive at the retina. It is corrected by the use of glasses which increase the divergency of the rays before they enter the cornea, and thereby throw their focus further back, so as to fall on the retina.

MY'RIAD. (Gr. *μυριας*.) Ten thousand. Often used as expressive of an indefinite multitude.

MYRIAME'TRE. A French measure equal to ten thousand meters; it is the equivalent of two leagues of the old measure. *See* MEASURES.

MY'RIAPODS, *Myriapoda*. (Gr. *μυριας*, *ten thousand*, and *πους*, *foot.*) The name of a class of Articulate animals, including those which have an indeterminate number of jointed feet, equalling that of the articulations of the body.

MYRI'CIN. That portion of wax which is insoluble in alcohol. The wax of the *Myrica cerifera* affords it.

MYRIOLI'TRE. A French measure of capacity equal to ten thousand litres, or 610280 cubic inches.

MYRISTICA'CEÆ. (Myristica, one of the genera.) A natural order of arborescent Exogens inhabiting the tropics. This has been placed, on account of its apetalous flowers, in *Lauraceæ;* from which it is distinguished by the structure of the calyx, anthers, and fruit. Brown places it between *Proteaceæ* and *Lauracæ;* but the order appears rather to be an apetalous form of *Annonaceæ*, with which the trimerous flowers, arillate seed, runcinated albumen, minute embryo, and peculiar properties almost identify it. The bark generally abounds in an acrid juice, which is viscid and stains red. The rind of the fruit is caustic; the aril and albumen of *Myristica moschata*, the former known under the name of *mace* and the latter of *nutmeg*, are important aromatics, abounding in a fixed oil of a consistence analogous to fat, which, in a species called *Virola sebifera*, is so copious as to be extracted easily by immersing the seeds in hot water.

MYRMECO'BIUS. (Gr. μυϱμηξ, *ant;* βιὸς, *life.*) A genus of Marsupial quadrupeds which feed on ants. The only known species, *Myrmecobius fasciatus*, is a native of Australia.

MYRMECO'PHAGA. (Gr. μυϱμηξ, and φαγω, *I eat.*) The name of a genus of Edentate quadrupeds which feed on ants, and are called *ant-eaters.* They are peculiar to the continent of South America.

MYRMELEO'NIDES. (Gr. μυϱμηξ, and λεων, *lion.*) The family of insects commonly called *ant-lions*, having the genus *Myrmeleon* as the type.

MY'RMIDONS. In Classical Mythology, a people on the southern borders of Thessaly, who accompanied Achilles to the Trojan war. Their name is derived by the mythologists from μυϱμηξ, *an ant;* and they were said to have arisen from ants, or pismires, in answer to a prayer of Œacus, king of the country, to Jupiter, after his kingdom had been depopulated by a pestilence.

MYRMILLO'NES. In Roman Antiquity, a species of gladiators, who fought completely armed against the Ectiarii. Their arms consisted of a sword, headpiece, and shield. On the top of the headpiece they wore a fish embossed, called μιϱμυϱος, whence, in all probability, their name is derived. The Myrmillones were also termed *Galli*, from their wearing Gallic armour; and *Scutatores*, from the shield by which they were defended.

MYRO'BALANS. (Gr. μυϱος, *an ointment*, and βαλανος, *a nut;* because formerly used in the preparation of unguents.) A bitterish austere fruit, brought from India, the produce of several species of *Myrobalanus.* Myrobalans are used by the Hindoos in calico printing and medicine; they were also formerly employed in Europe (though to a comparatively trifling extent) in the arts and pharmacy.

MYRRH. This gum resin is imported from Turkey: it is in irregular tears and lumps, of a reddish brown colour, a fragrant odour, and a warm but bitter taste. It is probably the produce of a species of *Amyris*, said to be a native of Abyssinia and Arabia Felix. It is a good stimulating tonic medicine, and is given in doses of from five to twenty grains.

MYRTA'CEÆ (Lat. myrtus), are an important natural order of Polypetalous Exogenous plants, of a woody texture, and frequently forming small trees, found in all tropical and temperate countries, where they are often cultivated for the sake of their valuable aromatic properties. The spices *cloves* and *pimento* are produced by some species; the agreeable fruits called *guava, jamrosade*, and *rose-apples* are yielded by others; while the enormous *gum-trees*, or *Eucalypti*, of New Holland, and the *Melæuca*, which furnishes the stimulating green oil of *cajeput*, also belong to the order. *Myrtaceæ* are nearly related to the Onagraceous order, from which they differ in having an indefinite number of stamens; and to *Melastomaceæ*, which have rostrate inflected anthers and ribbed leaves. Their most essential characters are to have polypetalous calycifloral flowers, indefinite stamens, round erect anthers, inferior fruit, and dotted leaves with an intra-marginal vein.

MYRTLE. (*Murt*, the Persian name, whence μυϱτος.) An evergreen fragrant bush, inhabiting all the warmer parts of the basin of the Mediterranean and of the west of Asia. It was considered sacred to Venus, and is at this day regarded with superstitious reverence by the Persian peasant. In the latitude of London the myrtle will endure the climate only in the warmest and most sheltered spots.

MYSTACI'NEÆ. (Gr. μυσταξ, *moustache.*) The name of a family of Infusories of the tribe *Trichoda*, including those which have superficial cilia, or fine hair-like processes, disposed in groups. Many species of animals derive their trivial name from the same root, as the *Vespertilio mystacinus*, or whiskered bat; the *Caprimulgus mysticalis*, or bearded goat-sucker; the *Cypselus mystaceus*, or bearded swift, &c.

MYSTERIES, SACRED. (The word mystery has been by some traced to the Hebrew סתר, to hide, whence *mystar*, a thing concealed; formed from which is the Gr. μυστηϱιον, old French *mestier* — English *mystery*, and old English *mistar*, a trade or *craft*, the learning of which was something occult and mysterious; but the more direct derivation appears to be from the Gr. μυεω.) The word mystery is primarily used in speaking of certain truths set forth in the Old and New Testament, to the full understanding of which human reason cannot attain. Thus all the Old Testament figures and prophecies were mysteries to the greater part of the Jews, until they received their accomplishment in Christ. Among the mysteries set forth in the New Testament the most prominent are, the doctrine of the satisfaction of Christ, the forgiveness of sins for the sake of his sufferings, and eternal life in a future world; the spiritual union between Christ and his church; the grace of Jesus Christ in its operation on our hearts; and the resurrection from the dead.

But the greatest of sacred or scripture mysteries is doubtless the incarnation of the Son of God:— the advent of Christ in the fulness of time, of the seed of Israel, and his participation in our nature, according to the flesh; "being in the likeness of man," and "found in fashion as a man," but "very God of very God," "God over all, blessed for ever." "The Word was *with* God and *was* God," says John; "and the Word was made flesh." This is the mystery, and, "without controversy, great is the mystery of godliness" (or God-*likeness*), God, manifest in the flesh," or "God *was* manifest in the flesh," as the most correct reading is held to be—Θεος εφανεϱώθη εν σαϱκι.

These are some of the numerous mysteries scattered throughout the Old and New Testament, and which rightly come under the denomination of *sacred* mysteries. For an account of *profane* mysteries, see *infra.*

MYS'TERIES, PROFANE. In the religions of Pagan antiquity, the secret rites and ceremonies performed by a select few in honour of some divinity were so called. "Each of the Pagan gods," says Bishop Warburton, "had, besides the public and open, a secret worship paid them, into which none were admitted but those who had been selected by preparatory ceremonies, called initiation; and this secret worship was termed *the mysteries.*" The first mysteries of which we have any account were those of Isis and Osiris in Egypt; whence they were introduced into Greece and Italy, and in process of time disseminated through the northern and western nations of Europe.

A very clear and concise account of the Egyptian mysteries has been given by Sir G. Wilkinson, in his *Manners and Customs of the Ancient Egyptians*, of which the following abstract will convey their peculiarities and importance:— "The Egyptian mysteries consisted of two degrees, denominated greater and less; and to become qualified for admission into the higher class the aspirant must have passed through those of the inferior degree. The priests alone could arrive at a thorough knowledge of the greater mysteries; but so sacred were these secrets held that many members of the sacerdotal order were not admitted to a participation in them at all, and those alone were selected for initiation who had proved themselves virtuous and deserving of the honour." "The Egyptians," says Clement of Alexandria, "neither intrusted their mysteries to every one, nor degraded the secrets of divine matters by disclosing them to the profane, reserving them for the heir-apparent * of the throne, and for such of the priests as excelled in virtue and wisdom." But there can be little doubt that at a later period the same liberality as to the admission of the laity which characterized the Eleusinian and other mysteries prevailed in Egypt, and that many laymen, and even some foreigners, were admitted to the lesser mysteries.

Of the origin of the Orphean and Eleusinian mysteries we have already spoken briefly, under their respective heads; but it has occurred to us that a more detailed account of the nature and ceremonies of the latter, more especially as with a few modifications, arising from the different habits of different nations, they constitute the great models on which all succeeding mysteries were formed, might not be considered out of place. These festivals were instituted at Eleusis, in honour of Ceres and Proserpine; the former of whom was believed to have taught the inhabitants the art of agriculture and the holy doctrine, — a doctrine which was said not only to purify the heart from sin, and expel ignorance from the mind, but to insure also the favour of the gods, and to open the gates of immortal felicity to the initiated. The mysteries, like those of Egypt, were of two kinds, — the less and the greater,—held at two different periods of the year, and at two different places: the lesser, which were introductory to the greater, being celebrated at Agræ, on the banks of the Ilyssus; the greater at Eleusis. The

* The kings of Egypt were the high priests of the nation, and by virtue of this office were partakers of these secrets; but if previously to ascending the throne they had been, which was frequently the case, members of the military class (one of the four great castes into which the Egyptians, like the Hindoos, were divided), they were required by the law to be admitted into the sacerdotal order, and instructed in all the secret learning of the priests, previously to exercising their priestly office.

celebration of the greater mysteries occupied nine days, chiefly devoted to sacrifices, processions, and other acts of worship; and during this period the judicial tribunals were closed; an armistice was proclaimed; private enmities were hushed; and death was decreed by the Athenian senate against any one, how high soever in rank, who should disturb the sanctity of the rites. The ceremonies of initiation into both the lesser and greater mysteries were conducted by four priests of the most illustrious families of Greece, called Hierophant, Dadouchos, Hierokeryx, and Epidomias; and these again were assisted by numerous inferior functionaries, to whom various appellations were given indicative of their several duties. The examination of those who had been purified by the lesser mysteries, and who were preparing for the greater, was apparently rigorous. All foreigners, all who had even involuntarily committed homicide, who had been declared infamous by the laws, or had been guilty of a notorious crime, were excluded; but these regulations were not immutable, for various instances might be produced to show that homicides and robbers were sometimes initiated.* Women and children were admissible; and a child, styled *the child of holiness*, whose innocence, it was believed, of itself endowed him with capacity to fulfil the requirements of the mysteries, was selected to conciliate the deity in the name of the initiated.

Of the ceremonies which attended the initiation we know little; since every postulant was required, under the most dreadful oaths, to conceal whatever he saw or heard within the hallowed precincts; and he who violated the oath was not only put to death, but devoted to the execration of all posterity. Yet the priests of ancient, like the Freemasons of modern times, could not prevent the disclosure of *some* facts. Crowned with myrtle, and enveloped in robes, which from this day were preserved as sacred relics, the novices were conducted beyond the boundary impassable to the rest of men. The hierophant, with his symbols of supreme deity, and his three assistants, representing the three other gods, were carefully visible. Lest any should have been introduced not sufficiently prepared for the rites, the herald exclaimed, "Far from hence the profane, the impious, all who are polluted by sin!" If any such were present, and did not instantly depart, death was the never-failing doom. The skins of new-slain victims were now placed under the feet of the novices, the ritual of initiation was read, and hymns were chanted in honour of Ceres. The novices moved on, while a deep sound rose from beneath as if the earth itself were complaining; the thunder pealed; the lightning flashed; and spectres glided through the vast obscurity, moaning, sighing, and groaning. Mysterious shades, the messengers of the infernal deities,—Anguish, Madness, Famine, Diseases, and Death,—flitted around; and the explanations of the hierophant, delivered in a solemn voice, added to the horrors of the scene. This was intended as a representation of the infernal regions, where misery had its seat. As they advanced, amidst the groans which issued from the darkness were distinguished those of the suicides—thus punished for cowardly deserting the post which the gods had assigned them in this world. But the scenes which the novices had hitherto beheld seemed to be a sort of purgatory, where penal fires and dire anguish, and the unutterable horrors of darkness, were believed, after countless ages of suffering, to purify from the guilt acquired in this mortal life. Suddenly the bursting open of two vast gates with a terrific sound dimly displayed to their sight, and faintly bore to their ears, the torments of those whose state was everlasting,—who had passed the bounds beyond which there is no hope. On the horrors of this abode of anguish and despair a curtain may be dropped; the subject is unutterable. Onwards proceeded the novices, and were soon conducted into another region; that of everlasting bliss, the sojourn of the just—of those whose hearts had been purified and whose minds had been enlightened by "the holy doctrine." This was Elysium—the joys of which were equally unutterable, equally incomprehensible, to mortals not admitted into these mysteries. Here a veil was in like manner thrown over *this* scene. (*Cab. Cyclop.*, vol. 61.)

Like most other questions of this nature, the origin and purpose of these religious institutions are involved in the deepest obscurity; and all the efforts of the learned that have been directed to the elucidation of this question in all ages, but more particularly in modern times, have ended only in unprofitable conjecture. Referring to the dissertations of Bishop Warburton and Dr. Leland for the chief views that have been entertained respecting them, we may here briefly observe, that though the mysteries seem to have been instituted for the purpose of enlightening the initiated as to the hidden meaning of religious doctrines and usages of which the great mass of the people were kept in ignorance, there are no means of approximating even to a conjecture as to the real nature of the doctrine taught in the mysteries, or the advantages of initiation. Were this the place for such discussions, we think it might be satisfactorily proved that mysteries must form an indispensable part in the religious ceremonies of every people who have attained to a certain degree of civilization. The mythological systems of antiquity were too gross, and the fables of which they were composed too senseless, to be believed by any one into whose mind the light of philosophy had dawned; and accordingly we find that many of the most distinguished persons embraced and inculcated in private (*see* MONOTHEISM) the most heterodoxical opinions respecting the national faith. These opinions were well known to the priests, many of whom were too enlightened to credit the delusions of which they were the ministers, and who might well tremble for the further spread of doctrines which must inevitably prove fatal to their influence. It became, therefore, a matter of state policy to divert into another channel those feelings of religious infidelity which, if communicated to the vulgar, might have ended in popular disturbances; and hence, in all probability, mysteries were instituted, which, while they ministered to the pride and vanity of human reason by elevating the initiated above the prejudices of ordinary persons, and gave as it were the sanction of the state to the entertainment of heterodoxical opinions, no less gratified the vulgar by the splendid shows and ceremonies of which they were the vehicle, at the same time that they held out the prospect of initiation to all who might be deemed worthy of the honour. (In addition to the works already quoted, see *Sir G. Wilkinson's Ancient Egyptians*, vol. ii. pp. 322—332., 2d Series; and the authorities there referred to.)

* It has been said that the division of the Eleusinian Mysteries into the lesser and great arose from the expiatory ablutions and other ceremonies which were imposed upon Hercules, when he aspired to initiation after killing the centaurs; but it is more probable that this division, which, as we have remarked above, was common to them with the Egyptian mysteries, was coeval with their introduction into Greece.

MY'STERIES. In Modern Literature, a species of dramatic composition, with characters and events drawn from sacred history. Saint Gregory Nazianzen composed the earliest sacred dramas extant, on the model of the Greek tragedies, but with Christian hymns substituted for the ancient chorus. The mysteries of the middle ages are thought by some to have been first introduced by pilgrims returning from the Holy Land. They originated among, and were probably first performed by, ecclesiastics. However serious and solemn the events which were represented in these singular compositions, there were invariably, in the later mysteries, two characters introduced to make sport for the multitude: namely, the Devil and the Vice,—a personage accoutred in a long jerkin, a cap with ass's ears, and a dagger of lath. He is now best remembered by the allusions to his character and office in the plays of Shakspeare. Miracles, or miracle-plays, were a species of mystery: they are usually said to have represented the martyrdoms of saints. In the 16th century, the mysteries were succeeded by moralities; which were much in vogue about the time when the Reformation made its chief progress in England. The characters in moralities were allegorical personages. Several of these performances, some by no means destitute of poetical merit, remain to us. They may be considered as the last step in the progress made by the dramatic art in modern Europe, before it reached the station and character which it has ever since retained.

MY'STICISM. In Religion, a word of very vague signification, applied, for the most part, indiscriminately to all those views or tendencies in religion which aspire towards a more direct communication between man and God, not through the medium of the senses, but through the inward perception of the mind, than that which is afforded us through revelation. Thus, the Pantheism of the ancient philosophers and many modern religionists, which supposed a God existing in all space and matter, and revealed to us in the outward manifestations of things; the Quietism of Madame Guyon, Fénélon, &c., who sought for direct revelation from the Divinity to the believer in a species of ecstasy; the Pietism of Molinos, &c.; the doctrines of the Illuminati in Germany; the visions of Swedenborg; and some of the notions prevalent among the Methodists and other sects among ourselves—all approximate to mysticism. See, as to the early Christian mystics of the East, the first volume of *Mosheim*; as to those of the West, the third (transl. ed. 1790, p. 352.).

MYTHO'LOGY. (Gr. μυθος, *fable*, and λόγος, *discourse*.) By the mythology of a people, we understand the collective body of its traditions respecting its gods and other fabulous preternatural beings. The classical mythology, *i.e.* that of ancient Greece and Rome, being the best known, is most frequently intended, when the word is used without a distinctive addition; but the mythologies of the ancient Egyptians, of the Hindoos, and of the northern nations of Europe, have also been sedulously examined by modern scholars, and reduced into systems pretty generally known. The learned although singular work of Bryant, *Analysis of Ancient Mythology*,

is a rich repertory of traditions and doctrines, though arranged with a view to the author's own far-fetched theory. *Keightley's Mythology of Ancient Greece and Italy* is perhaps the most useful manual of those subjects. The work of Creuzer, *Symbolik der Alten Völker, besonders der Griechen*, may be considered among the most erudite and valuable of all books on classical antiquities. An outline of the chief mythological systems of antiquity will be found under the article POLYTHEISM, to which we beg to refer; and the chief mythological personages are noticed under their particular heads.

MYTILA'CEANS, *Mytilacea*. (Gr. μυτιλος, *a mussel.*) The name of the family of Lamellibranchiate Mollusks, having the genus *Mytilus*, or common mussel, for its type, and characterized by the mantle being open anteriorly, and by having a foot either sufficiently developed for the office of progressive motion, or serving to draw out, direct, and fix the byssus.

MY'TILUS. (Gr. μυτιλος, *a mussel.*) A name applied by Linnæus to all those testaceous Vermes having a bivalve shell, rough, and generally affixed by a byssus, with a hinge, mostly without teeth, generally with a subulate, excavated, longitudinal line. The species comprehended under the above phrase are placed by Cuvier in the Testaceous order of Acephalous Mollusks, and have been subdivided into the genus *Mytilus* proper, of which the common edible mussel (*Mytilus edulis*) is an example; *Modiolus*, Lam.; *Lithodomus*, Cuv.; *Anodonta*, Brug.; *Avicula*, Brug.; *Meleagrina*, Lam., which produces the most precious pearls. Extensive establishments are maintained at Ceylon and other places for the express purpose of collecting the *Meleagrina margaritifera*, or pearl oyster.

MY'XINE. (Gr. μυξα, *mucus.*) The name of a genus of Cyclostomous fishes, remarkable for their mucous slippery integument: the species called glutinous hag (*Myxine glutinosa*) is a native of the British seas. Its habits are parasitic, and it is most commonly met with in the interior of a cod upon whose flesh it has been preying.

N.

N. One of the liquid series of letters. It is common to all known languages, and is interchangeable, more particularly in the Latin and Greek languages and those derived from them, with a variety of letters. As an abbreviation N is used for *north*, *numero*, &c.; N. B. for *nota bene;* N. L. for *non liquet* (*i.e.* the cause is not clear enough to pass sentence on); N. P. for *notarius publicus*, &c.

NA'BLUM. One of the most famous musical instruments among the Hebrews; but one whose form and nature are so little known that Calmet thinks it was a harp, Kircher a psaltery or stringed instrument of percussion played on by sticks, and Harmer (*Observations on Scripture*) hints at its being a bagpipe. Bythner (*Lyra*) says the *nebel* (נבל) was like a leathern bottle, explaining his meaning to be that it bore a resemblance to the ancient Greek and Roman lyre, whose body was made of the shell of the tortoise. The authority of Josephus (*Ant. Jud.* lib. vii. c. 12.), if to be relied upon, distinctly shows it was not an instrument of percussion, but played upon with the fingers; his words are, "Ηδε ναβλα δωδεκα φθογγους εχουσα, τοις δακτυλοις κρουεται. Its having twelve sounds, without telling how those sounds were produced, whether by strings or wind, leaves the matter so doubtful that the reader must decide for himself.

NABO'B. (A corruption of nawâb, from naib, *a deputy.*) The title of the governor of a province or commander of an army, in India, under the domination of the Moguls. The nabob was, properly speaking, a subordinate provincial governor under the subahdar; *i. e.* governor of a subah, or larger province. In the decay of the Mogul empire, many of the nabobs became virtually independent, until their dominions were reduced by the English. The term nabob is vulgarly applied to those Europeans who have amassed a large fortune in the East Indies, and live in eastern splendour.

NA'CARAT. (Span. nacar, *mother of pearl.*) A term applied to a pale red colour with an orange cast. The *nacarat* of Portugal is a crape or fine linen fabric, dyed fugitively of this tint, which is used by ladies to give their countenances a roseate hue. The brightest red crapes of this kind are manufactured by the Turks of Constantinople. (*Ure's Dictionary of Arts.*) *See* ROUGE.

NA'CREOUS. (Fr. nacré, *pearl.*) In Zoology, when the surface of a shell or other part reflects iridescent light.

NA'CRITE. (Fr. nacré.) A mineral of a pearly lustre, found crystallized in granite. It is a silicate of alumina and potassa.

NA'DIR. (Arab. nazeer, *opposite.*) In Astronomy and Geography, the point of the heavens diametrically opposite to the zenith. The zenith and nadir are the two poles of the horizon.

NÆ'NIA. In Roman Antiquities, a funeral dirge sung to the music of flutes. It is also the name of the Roman goddess who presided over lamentations.

NÆ'VUS. A natural spot or mark upon the skin of children at birth.

NAI'ADS. (Gr. ναιω, *I inhabit*, or ναω, *I flow.*) In the ancient Roman and Greek Mythology, female deities who presided over fountains, rivers, brooks, &c. The number of these goddesses was indefinite. In his *Georgics* (book iv.) Virgil enumerates 16; and Ovid, in his *Elegies* (book iii. 64.) speaks of at least 100 in the river Anio. The most beautiful of the Naiads is said to have been Aigle (*Virg.*, Ec. 6.). Many of the Homeric heroes are represented to have been the offspring of these deities.

NAILS. (Germ. nägel.) This term is given to the terminal horny appendages of the fingers and toes when they are in the form of flattened or depressed plates, serving to support a broad tactile surface, as in the human fingers. When these appendages are compressed, curved, pointed, and extended beyond the digit, they are called "talons," or "claws;" when they encase the extremity of a digit like a box, they are called "hoofs."

NA'IS. (Gr. ναϊας, *a naiad.*) The name of a genus of minute Abranchiate Anellides, or red-blooded worms, remarkable for their powers of reproducing parts of the body when mutilated; and for procreating their kind by spontaneous separation of the hinder segments of the trunk.

NAI'VETÉ (Fr.), is applied to a certain indescribable grace in the female character, resulting from a union of great natural shrewdness, unaffected simplicity, and, to a certain extent, a disregard of the conventional forms and usages of society.

NA'KED FLOORING. In Architecture, the timber work of a floor, which supports the boarding or ceiling, or both.

NAME. (Lat. nomen; Germ. nome; Fr. nom.) The designation by which any individual is known. The custom adopted in personal nomenclature has been based on some uniform principle since the earliest ages; modified, however, by the varying circumstances of different countries, and according to the more or less advanced state of civilization of every people. Thus in the early state of society of the Jews, Egyptians, Persians, Greeks, Romans, Germans, Gauls, Britons, and indeed of every nation, no individual had more than one name; but in a more advanced or refined period one or more additional names were given, in order to mark the different families to which individuals belonged, as well as to distinguish members of the same family from each other. To effect these objects the ancient Romans, at least those of good family, generally used three names,—the *prænomen*, the *nomen*, and the *cognomen;* the first, which was given on the assumption of the *toga virilis*, marked the individual, like our Christian name; the second distinguished the *gens* (which see), and the third the *familia* (which see), to which he belonged. To these, however, was sometimes added a fourth name, called the *agnomen*, which was derived from some distinguishing peculiarities in each individual's character or condition; thus Publius Cornelius Scipio was named *Africanus*, from his exploits in Africa. The mode of designation adopted in all the countries of modern Europe is founded on a principle somewhat analogous to that of ancient Rome; with this prominent difference, that in the former no *nomen* or *clan* appellation intervenes between the *prænomen* (or Christian name) and the *cognomen* (or surname). It would be difficult to give any satisfactory reasons for the adoption of the Christian and surnames most commonly met with among ourselves. Those who are inclined to prosecute inquiry into this comparatively untouched subject, will find some ingenious hints for their guidance in the *Penny Cyclopædia* (art. "Names, Proper"), to which we beg to refer. *See* SURNAME.

NA'NDU. The name of the American ostrich (*Rhea Americana*). *See* RHEA.

NANKEE'N. A yellowish or buff-coloured cotton cloth, largely manufactured at Nankin, in China. Its colour is that of the cotton wool of which it is manufactured. They are sometimes bleached, and then are called *white nankeens*. Imitation nankeens are manufactured at Manchester; but it is admitted these are of an inferior quality to the Chinese, neither lasting so long, nor holding their colour so well.

NANTES, EDICT OF. *See* EDICT.

NA'OS, or NAVE. (Gr. ναος, *a temple*, or ναυς, *a vessel.*) In Architecture, that part of a temple enclosed by the walls. The part in front of it was called *pronaos*, and that in the rear *posticum*. In modern architecture, it is the middle part or alley of a church, between the aisles or wings.

NA'PHTHA. A limpid bitumen, which exudes from the earth upon the shores of the Caspian and some other Eastern countries. Near the village of Amiano, in the state of Parma, there exists a spring which yields this

substance in sufficient quantity to illuminate the city of Genoa, for which purpose it is employed. It has a peculiar odour, and generally a yellow colour, but may be rendered colourless by distillation. Its specific gravity is about 0·75. It boils at about 160°. It is highly inflammable, burning with a white smoky flame. It appears to be a compound of 36 of carbon with 5 of hydrogen, and is therefore a pure hydro-carbon. A liquid very similar to mineral naphtha is obtained by the distillation of coal tar. It has sometimes been used in lamps, but is apt to smoke. This variety of naphtha is in great request as a solvent for caoutchouc.

NA'PHTHA'LAMIDE. A compound obtained by distilling napthalate of ammonia.

NAPHTHA'LIC ACID. A crystalline product, resembling in appearance benzoic acid, obtained by Laurent from naphthaline.

NA'PHTHALINE. A substance formed during the destructive distillation of pit-coal for the production of gas. It is obtained by re-distilling the coal tar. It is a white crystalline substance, heavier than water, and of a peculiar aromatic odour. It is extremely volatile, fusing at 180°, and its vapour condenses in large white flaky crystals. It burns with much smoke, and dissolves in alcohol and ether. It consists of 60 carbon, 4 hydrogen, and is therefore a hydro-carbon. It combines with sulphuric acid to form the *sulpho-naphthalic acid*.

NAPIER'S RODS, or BONES. An instrument contrived by the celebrated Lord Napier, the inventor of the logarithms, for the purpose of performing mechanically the arithmetical operations of multiplication and division. Napier's rods consist of small squared pieces of bone or ivory, box or silver, about 3 inches long, and 3-10ths of an inch in breadth, the faces of which are divided into nine little squares or cells, each of which is parted by a diagonal into two triangles. On these cells are engraved the successive columns of the common multiplication table, in such a manner that the units, or right-hand figures, are found in the right-hand triangle, and the tens, or left-hand figures, in the left-hand triangle. Thus: —

1	1	2	3	4	5	6	7	8	9	0
2	/2	/4	/6	/8	1/0	1/2	1/4	1/6	1/8	/0
3	/3	/6	/9	1/2	1/5	1/8	2/1	2/4	2/7	/0
4	/4	/8	1/2	1/6	2/0	2/4	2/8	3/2	3/6	/0
5	/5	1/0	1/5	2/0	2/5	3/0	3/5	4/0	4/5	/0
6	/6	1/2	1/8	2/4	3/0	3/6	4/2	4/8	5/4	/0
7	/7	1/4	2/1	2/8	3/5	4/2	4/9	5/6	6/3	/0
8	/8	1/6	2/4	3/2	4/0	4/8	5/6	6/4	7/2	/0
9	/9	1/8	2/7	3/6	4/5	5/4	6/3	7/2	8/1	/0

As an example of the manner in which the rods are used, let it be required to multiply the numbers 6795 by 4876. Select the rods which have the figures of the multiplicand inscribed at the top, and place them in their order, with the index rod before them, when they will stand as in the table annexed. Then, opposite to the several figures of the multiplier, 4876, on the index, but proceeding backwards, take the numbers in each horizontal column; add the pair of digits in each rhombus formed by the adjacent triangles of two contiguous cells; and, finally, collect into one sum the rows of the products corresponding to each digit of the multiplier, transcribed and properly disposed, as under: —

1	6	7	9	5
2	1/2	1/4	1/8	1/0
3	1/8	2/1	2/7	1/5
4	2/4	2/8	3/6	2/0
5	3/0	3/5	4/5	2/5
6	3/6	4/2	5/4	3/0
7	4/2	4/9	6/3	3/5
8	4/8	5/6	7/2	4/0
9	5/4	6/3	8/1	4/5

40770	6
47565	7
54360	8
27180	4
33132420	

Here, opposite to 6, the last digit of the multiplier, and proceeding from the right along the horizontal column, there occur the figures — first, 0, then 3 and 4, or 7; 5 and 2, or 7; 4 and 6, or 10; and lastly, writing down the cipher, and carrying 1 to the 3, we get 4. These collected together give 40770 for the product of 6795 by 6. In the same manner the other rows are formed, which, being added in the usual manner, the product of the two given numbers is obtained. It is obvious that this method of calculation is much too tedious to be of any real use.

NA'PLES YELLOW. A celebrated yellow pigment, formerly made by a secret process at Naples, and used not only in oil painting, but as an enamel colour; it is said to be a mixture of the oxides of antimony, lead, and zinc.

NAPOLEON, CODE OF. It was in 1802, during the temporary calm of the Peace of Amiens, that Napoleon, then First Consul, undertook the great task of forming a civil code. It was entrusted to a commission of the council of state; of which Tronchet, Rœderer, Portalis, Thibaudeau, Cambacérés, Lebrun, were the leading members. "Tronchet" (said Napoleon himself to Las Casas) "was the soul of the code." (*Memoirs*, part 3. 234.) And Portalis has also the credit of a very important share in its composition. But Napoleon himself took great interest in the subject, and mingled eagerly in the discussions of the commission, as appears by the procès-verbal of those discussions. After all allowances made for the unparalleled flatteries of the Napoleonists, his observations are said to show great intuitive sagacity, much readiness, and a peculiarly inquiring disposition, which often led him to the principles of things, while men of less natural power and trained in a different school were busying themselves unprofitably with the matters on the surface. "I had at first fancied," he says, "it would be possible to reduce all laws to simple geometrical demonstrations, so that every man who could read and connect his ideas together would be able to decide for himself; but I became convinced almost immediately after that this idea was absurd." (*Las Casas, Mem.*, part 6. 263.) Still, according to himself, he continued to cherish the scarcely less absurd idea that no other laws might be necessary than those inserted in the code. The second volume of the work of Thibaudeau (*Sur le Consulat et l'Empire*) is perhaps the most useful to consult for the history of these discussions. According to him, the secretary Locré did not in any degree improve the speeches of the First Consul in his report. Although the ideas of Napoleon himself are said to have entered largely into the composition of the code, it does not appear clearly in what important particulars this was the case; except in one singular instance, that of the law of divorce (book 1. title 6.), the liberty of which he is said to have greatly promoted. The Code Civil is composed of a great number of laws, dated from the "14 Ventose, an 11" (March, 1803), to 24 Ventose, an 12 (March, 1804), in which latter month they were united in a single code; and which was republished under the empire in 1807. The "Code de Procédure Civile" was put in force on the 1st January, 1807; the Code of Commerce dates from the same year; the "Code d'Instruction Criminelle" from November, 1808; the "Code Pénal" from February, 1810; which last is a revision of the "Code Pénal" and "Code des Délits et des Peines" of the Revolution. But the "Code Civil" is that to which the term "Code Napoleon" is in common language particularly applied. It consists of three books; the first "of persons," subdivided under eleven titles; the second "of goods (biens), and the different modifications of property," comprising four titles; the third "of the different manners in which property is acquired," with twenty titles. These last are again subdivided into chapters and sections; and the whole code consists of articles numbered in arithmetical order through the whole, in all 2281. The most important provisions of the code as to the civil state of persons are those relating to marriage and divorce. With regard to property, its fundamental law is that of equal succession by heirs, the abolition of most distinctions between landed and moveable property, and the restraint imposed by it on the testamentary power: making in all a system "fundamentally at variance with that of all the other states of Europe, and of which the ultimate consequences are destined to be more important than any of the other changes brought about by the Revolution." (*Alison's History of the French Revolution*, vol. vi.) But in this respect the Code Napoleon merely consolidated the revolutionary laws already existing. *See* CODE.

NA'POLITE. A blue mineral from Vesuvius.

NARCE'IA. (Gr. *ναρκη*, *torpor*.) A vegeto-alkaline base, contained in opium, and discovered by Pelletier in 1832. Its salts have the peculiarity of being blue in a certain degree of concentration, and on adding successive quantities of water to them the colour changes to violet and red, and lastly disappears. By this character, and by its easy fusibility (at 198°), it is distinguished from the other principles with which it is associated. Its medical virtues have not been ascertained, nor has its equivalent number been determined.

NARCI'SSUS. In Mythology, the beautiful son of Cephesus and the nymph Liriope, whose history formed one of the most favourite topics with the poets of classical antiquity. Though beloved by all the Grecian nymphs, he treated them with contemptuous indifference; but having accidentally seen his own image reflected in a fountain, he became so enamoured of it that he languished till he died, and thus realized the prophecy of Tiresias, that he should live until he saw himself. After his death the gods, moved with compassion for his fate, changed him into the flower which bears his name.

NARCISSUS. In Botany, a genus of Endogens belonging to the natural order of *Amaryllidaceæ*, "among which it is known by its flowers growing upon a scape, and having a cup at their mouth," the stamens opposite the sepals being longer than the others. The species are very numerous; and from their delicate shape, soft and various colour, and sweet scent, have long been favourite objects of cultivation, especially the daffodils, jonquils, and tazzettas. Some of the more hardy species grow wild in our woods and under our hedges; but the finer sorts are natives of more southern latitudes.

NARCO'TICS. (Gr. ναρκη, *torpor.*) Medicines which produce drowsiness, sleep, and stupor. They appear, in the first instance, to act as stimulants, quickening the pulse, and rousing the energy of the nervous system, and, in very small doses, this is their most obvious operation. In larger doses these effects are followed by a tranquil state of mind, torpor, and even coma. Considerable skill and experience are required in the successful administration of these medicines, both as regards the cases in which they are to be prescribed, the doses in which they are to be given, and the peculiarities of habit which often interfere with and modify their usual effects. They are to be distinguished from *sedatives*, which do not produce preliminary excitement. Opium is a narcotic, henbane a sedative.

NARCO'TINE. (Gr. ναρκη.) A crystallized substance, obtained by digesting the aqueous extract of opium in ether, and evaporating the ethereal solution. It was discovered in 1803 by Derosne, and supposed to be the narcotic principle of opium; but this has since been shown to reside more exclusively in *morphia*, and narcotine is possessed rather of stimulant qualities, and is the cause, perhaps, of the excitement which opium occasions. It consists of 65 carbon, 5·50 hydrogen, 2·50 nitrogen, and 27 oxygen.

NARRA'TION. (Lat. narro, *I tell.*) In Rhetoric, the term usually applied to the second division of an oratorical discourse, in which the facts of the case are set forth from which the orator intends to draw his conclusions. This part of a discourse should be characterized by the greatest simplicity of style, as well as by absence of all rhetorical ornaments.

NARWHAL. The common name of the species of Cetacean which has a single long protruded tusk. *See* MONODON.

NA'SAL. (Lat. nasus, *nose.*) A nasal pronunciation is given in some languages to particular letters, as in French to the letters *n* and *m* in certain positions. The only sound approaching to nasal in English is that of the double consonant *ng;* as in *thing*, *ring*, &c.

NASALIS. *See* SEMNOPITHECUS.

NA'SCENT STATE. Chemists generally apply this term to gaseous bodies at the moment of their evolution, as it were, from liquids or solids, and before they have assumed the aëriform state. There are numerous cases in which bodies having no tendency to combine under ordinary circumstances readily unite when presented to each other in their nascent states. Hydrogen and nitrogen gases, for instance, when mixed together, show no disposition to combine; but when certain organic bodies containing those elements are heated, they are evolved in their nascent states, and combine so as to form ammonia; it is in this way that ammonia is abundantly produced during the destructive distillation of many kinds of animal matter, and of pit coal.

NASI'LUM (Lat.), among the ancient Romans signified *freight*, whence it was used for a piece of money put into the mouths of deceased persons to enable them to pay Charon for ferrying them over the Styx. A similar custom prevailed among the Greeks.

NA'SUA. (Lat. nasus, *a nose.*) A genus of Plantigrade Mammalia, so called from the remarkable elongation and upward curve of the nose. The species of this genus, *N. rufa*, or red coati, and *N. fusca*, or brown coati, are both natives of South America. They climb trees in pursuit of birds, and to rob their nests; they burrow for shelter at the foot of large trees, and often undermine them to such an extent that they are liable to be overturned even by a slight wind.

NASU'TA. (Lat. nasus.) A term in Zoology, signifying the prolongation of the muzzle into the form of a nose, as in the *Perameles nasuta*, *Pleuronectes nasutus*, *Truxalis nasutus;* or the development of the integument of the face above the muzzle, forming a true nose, as in the proboscis monkey, *Simia nasuta*. Illiger called a family of Multungulate quadrupeds with the nose prolonged beyond the jaws, and moveable, as in the tapir, *Nasuta*.

NATA'LIS DIES, *Birthday*. A day celebrated with much ceremony by the ancients. Of these there were four, which all Roman citizens were bound to observe; viz. those of the gods, of their emperors, of distinguished persons, and their own. On such occasions every Roman was arrayed in white, and in all his ornaments; among which a ring, called by way of eminence the *annulus natalis*, was conspicuous. Sacrifices were offered to the *genius* (which see) of the person; and the day concluded with a sumptuous entertainment, to which friends and kindred were invited.

NATATO'RES. (Lat. nato, *I swim.*) Swimming birds. The name of the order of birds including those in which the toes are united by a membrane, whence the order is also termed *Palmipedes*. The legs are placed behind the equilibrium, and the body is covered with a thick coat of down beneath the feathers.

NA'TATORY. (Lat. nato.) In Zoology, when a locomotive extremity, or other part, is provided with a membrane, or with close-set hairs, by which it is adapted for displacing water.

NA'TION. (Lat.) A collective appellation for a people inhabiting a certain extent of territory under the same government. The word is also used in some universities, by way of distinguishing students of different districts or countries, as the case may be. This latter meaning is borrowed from the custom that was adopted in the University of Paris previously to the institution of faculties, when those who resorted to it from different countries lived under the same institutions and masters, a *common country*, however, being the only bond of union.

NATIONAL DEBT. In Political Economy and Finance, the amount of the sums or obligations owing by a nation or state.

In modern times, it has been customary in most countries, on the occurrence of any circumstances that occasion any considerable increase of expense, to borrow either the whole or some portion thereof, paying a certain stipulated interest for the same. In this country, the practice of borrowing money, in order to defray part of the war expenditure, was introduced in the reign of William III. And how much soever opinions may differ as to the policy of borrowing or funding in ordinary times, it could not, at its introduction into Great Britain, be dispensed with. The Revolution involved us in a bloody and expensive contest with Louis XIV., then in the zenith of his power, who espoused the cause of the exiled family of Stuart. But, though great and imminent, the danger from without was inferior to that from within. A numerous and powerful party were favourable to the views of the Pretender; and the imposition of such additional taxes as would have been required to defray the heavy cost of the contest we were forced to wage for our liberties and religion would have given a violent shock to industry, and afforded the Jacobites the means of traducing the new government, fomenting popular discontent, and most probably of overturning the revolutionary establishment. Under such circumstances, the contraction of debt was not really a matter of choice, but of necessity. The error, if there have been any, consisted in continuing the system of loans after the new government was firmly established, and when either the whole or a larger portion of the war expenditure might have been defrayed by taxes raised within the year.

In the infancy of the funding system, it was customary to borrow upon the security of some tax, or portion of a tax, set apart as a fund for discharging the principal and interest of the sum borrowed. This discharge was, however, very rarely effected. The public exigencies still continuing, the loans were, in most cases, either continued, or the taxes were again mortgaged for fresh ones. At length the practice of borrowing for a fixed period, or, as it is commonly called, upon *terminable* annuities, was almost entirely abandoned, and most loans were made upon *interminable* annuities; that is, government undertake to pay the lenders of any given sum a certain annuity in all time to come, or till they find it convenient to pay off the principal; but the lenders have no right or title to demand payment of the latter, that being a matter entirely at the option of government, who may either pay it or not, as they think fit.

In the beginning of the funding system, the term fund meant the taxes or funds appropriated to the discharge of the principal and interest of loans; those who held government securities, and sold them to others, selling, of course, a corresponding claim upon some special fund. But after the debt began to grow large, and the practice of borrowing upon interminable annuities had been introduced, the meaning attached to the term fund was gradually changed; and instead of signifying the security upon which loans were advanced, it has for a long time signified the principal of the loans themselves.

During the reigns of William III. and Anne, the interest stipulated for loans was very various. But in

the reign of George II. a different practice was adopted. Instead of varying the interest upon the loan according to the state of the money market at the time, the rate of interest was generally fixed at 3 or 3½ per cent.; the necessary variation being made in the principal funded. Thus, suppose government were anxious to borrow, that they preferred borrowing in a 3 per cent. stock, and that they could not negotiate a loan for less than 4½ per cent., they effected their object by giving the lender, in return for every 100*l*. advanced, 150*l*. of 3*l*. per cent. stock; that is, they bound the country to pay him or his assignees 4*l*. 10*s*. a year in all time to come, or otherwise to extinguish the debt by a payment of 150*l*. In consequence of the prevalence of this practice, the principal of the debt now existing amounts to nearly 2-5ths more than the sum actually advanced by the lenders.

This system of funding has been in the last degree injurious, though some advantages are either derivable or supposed to be derivable from it. No doubt it renders the management of debt, and its transfer, more simple and commodious than it would be, did it consist of a number of funds bearing different rates of interest; and it is contended that the greater field for speculation afforded to the dealers in stocks bearing a low rate of interest has enabled government to borrow, by funding additional capitals, for a considerably less payment, on account of interest, than would have been necessary had such increase of capital not been made.

In point of fact, however, these advantages are inconsiderable, while the disadvantages inseparable from the practice of funding a large amount of stock at a low rate of interest are great and signal. During war, especially if any considerable portion of its expenditure be defrayed by means of loans, the rate of interest uniformly rises, and is usually much higher than during peace. If, therefore, loans were funded in stocks bearing a rate of interest equivalent to the market rate when they were contracted for, the charge on their account might be reduced soon after the return of peace, according to the fall in the rate of interest; whereas, when loans are funded in stocks bearing a low rate of interest, with a corresponding increase of capital, it becomes impossible to take advantage of the fall of interest at the return of peace, and the country is burthened with the war interest in all time to come! It is not easy to exaggerate the injury we have sustained by overlooking this plain principle. In 1815, to specify only one of many similar instances, government bargained for a loan of 27,000,000*l*., it being stipulated that every subscriber of 100*l*. should be entitled to 174*l*. 3 per cent. stock, and 10*l*. 4 per cent. stock, making the interest paid on the loan 5*l*. 12*s*. 4*d*. per cent. The great improvidence of this transaction is obvious. Had from 5*l*. 15*s*. to 6*l*. per cent. of interest been paid for the loan, it might have been obtained without funding any additional capital; and had that been done, we should have been able, within two or three years, in consequence of the fall of interest after the peace, to reduce the charge on account of the loan to 3 or 3½ per cent.; but, owing to the way in which the contract was made, we have not had and will not have any means of reducing the exorbitant charge on account of this loan, so long as the market rate of interest is above 3 per cent., except by paying 174*l*. for every 100*l*. originally received, exclusive of the 10*l*. of 4 per cent. stock! But this, as already stated, is only one instance out of many of the same sort. We believe, indeed, that we are within the mark, when we affirm, that, owing to this erroneous method of funding, the country is at present paying from 6,000,000*l*. to 7,000,000*l*. a year on account of the public debt more than it would have had to pay had the same sums been borrowed and funded without any increase of capital.

We have said that an interest of from 5*l*. 15*s*. to 6*l*. per cent., instead of the stipulated interest of 5*l*. 12*s*. 4*d*. per cent., would have enabled the loan of 1815 to be funded without any increase of capital. Now, this is not a hypothetical statement. In the year in question, 11,000,000*l*. of exchequer bills were funded in a 5 per cent. stock, at the rate of 117*l*. stock for every 100*l*. exchequer bills. This was equivalent to an interest of 5*l*. 17*s*. per cent., being only 4*s*. 8*d*. more than the interest paid on the loan, though the subscribers to the latter had 84*l*. of artificial capital created for every 100*l*. advanced, and the holders of the bills only 17*l*. of artificial capital. But, in point of fact, the differences in the rates of interest, after allowing for certain circumstances connected with the loans, amounted to only 2*s*. 2*d*. per cent. This shows how little the saving in the charge on account of interest, by funding increased capitals, deserves to be considered as at all detracting from the great public loss occasioned by indulging in so wasteful a practice. (For a further and full discussion of this subject, see the *Edinburgh Review*, No. 93. art. iii.)

That this improvident system should have been so extensively acted upon by our finance ministers during the American and French war is the more surprising, seeing that experience had already demonstrated the advantages of funding limited capitals at a comparatively high rate of interest. Owing partly to the scarcity of capital, but much more to the supposed instability of the revolutionary establishment, the loans during the reigns of William III. and Anne were mostly contracted at a very high rate of interest. The stock created was the exact amount of the loans, the interest on it being increased according to the supposed insecurity of the government, the scarcity of floating capital, &c. Now, mark the consequences of this: so early as 1716, Sir Robert Walpole, availing himself of the greater facility with which money was procured after the treaty of Utrecht, and of the greater stability of the government, was able, by offering to pay off the creditors, to reduce the charge on account of the debt from 1,598,602*l*. to 1,274,146*l*., being a saving of 324,456*l*., or about one fifth part of the entire charge. And in 1749, during the administration of Mr. Pelham, the interest was again reduced from 4 to 3 per cent.; a measure which produced a fresh saving of 565,000*l*. a year.

Happily the practice of funding in a 5 per cent. stock was not entirely abandoned during the late war. In 1822, the total British and Irish 5 per cent. stock amounted to about 150,000,000*l*.; and, by offering to pay it off, a reduction of interest was then effected to the extent of about 1,200,000*l*. a year. And since that period, further savings have been effected by the reduction of the interest on the 4 and 4½ per cent. stock. But, unfortunately, the far greatest proportion of the debt created during the late war, and that with the American colonies, was funded in the 3 per cents.; and, as already stated, the charge on that portion has, in consequence, been hitherto, and will most probably continue to be, unsusceptible of diminution.

Payment of National Debt. Sinking Fund. — The payment of the national debt can be effected only by applying to that purpose such surplus revenues as the treasury may have to dispose of. But it was contended by the founders of the sinking fund, established in 1716, and still more strongly by Dr. Price and Mr. Pitt, the founders of the sinking fund of 1786, that if a sinking fund were formed, by applying a certain amount of revenue to buy up stock, and if the dividends on the stock so bought up were afterwards uniformly applied to the same object, such sinking fund would increase at *compound interest*, so that the largest amount of debt might be defrayed almost without an effort. Dr. Price illustrated the operation of this principle by calculating the number of *globes of gold* to which a penny, laid out at compound interest at the birth of Jesus Christ, would now amount to! But though a calculation of this sort be theoretically true, it is practically false and absurd. The truth is, that no sinking fund, even though it consisted of a clear surplus revenue, ever really operates at compound interest. It is true that, by constantly applying the same original amount of free revenue and the dividends accruing on the stock purchased by it to buy up fresh stock, the reduction of the debt is effected in the *same way* as if the free surplus revenue had been increasing, by an inherent energy of its own, at compound interest; but it is essential to know that though the *modus operandi* be the same, the means are radically and totally different. The debt is reduced because a portion of the produce of the taxes is systematically applied to pay it off, and it can never be reduced by any other means. To make capital increase at compound interest, it must be employed in some sort of productive industry; and the profits, instead of being consumed as income, must be regularly added to the principal, to form a new capital. It is unnecessary to say that no such sinking fund has ever existed. Those that have been set on foot in this and other countries have all been supported either by loans or by the produce of taxes, and have never paid off a single farthing of debt by their own agency.

It is clear, from this statement, that when there is no surplus revenue, there can be no sinking fund. Dr. Price, however, did not scruple to lay it down broadly, that to suspend the sinking fund during war, though the expenditure might then greatly exceed the income, would be the greatest imaginable folly. (*Appeal to the Public on the Subject of the National Debt*, p. 17. ed. 1774.) And inconceivable as it may now appear, all parties in parliament concurred in the soundness of this opinion, and approved the policy of keeping up the sinking fund machinery during the whole of last war. Hence the loans for the service of the year had to be increased by the entire amount of the sums placed at the disposal of the sinking fund commissioners; so that for every shilling's worth of stock transferred to them by this futile proceeding, an equal amount of *new debt* had to be contracted, exclusive of the loss incurred through the expense of management, &c.

For upwards of twenty years this contemptible juggle was kept up; parliament and the nation believing, notwithstanding the most decisive experience to the contrary, that it was rapidly diminishing the public debt. Dr. Hamilton of Aberdeen has the merit of having dissipated this delusion, the grossest, certainly, that ever im-

posed on any people. He showed, in his work on the National Debt, published in 1813, that the sinking fund, instead of diminishing, had really added to the debt; and he proved to demonstration that the *excess of revenue above expenditure* is the only sinking fund by which any part of the national debt can be discharged. "The increase of revenue," he observes, "or the diminution of expense, are the only means by which the sinking fund can be enlarged, and its operations rendered more effectual; and all the schemes for discharging the national debt, by sinking funds operating at compound interest, or in any other manner, unless in so far as they are founded upon this principle, are completely illusory."

The entire amount of the debt contracted from 1792 to 1816, both inclusive, amounted to 584,874,557*l.*; but of this no less than 188,522,350*l.* was made over to the commissioners of the sinking fund to be laid out in the paying off debt. But it must not be supposed that the influence of the sinking fund was negative merely, or that it was confined to the futile operation of making money be borrowed with the one hand that it might be paid off with the other. It is clear that a process of this sort could not take an atom from the public debt; but, in point of fact, it added considerably to its amount. Had the sinking fund not existed, the amount of the loans contracted during the war would have been fully a third less than they really were; and, as the rate of interest is always greater on large than on smaller loans, it follows, had this miserable juggle not been kept up, that the money borrowed from 1792 to 1816 would have been obtained at a reduced charge, at the same time that the expenses of its management would have been saved. The sinking fund has, therefore, been a costly as well as a delusive piece of quackery. The loss it entailed on the country during the war has been estimated, apparently on reasonable grounds, at above 600,000*l.*

At length the folly of contracting debt, for no other purpose but to pay it off, became obvious to every one; and the nominal amount of the sinking fund began to be diminished after the close of the war. In 1819, it was attempted to form a real sinking fund of 5,000,000*l.*; that is, to maintain a real surplus revenue of that extent. But as this could not always be done, after various modifications an end was put to the entire system in 1829; the act 10 Geo. 4. c. 27. having enacted, that the sum applicable in future to the reduction of the national debt should be the surplus, if any, of the total revenue beyond the total expenditure of the kingdom.

Distribution of the Dividends, or Interest on the National Debt. — It appears, from the subjoined account of the number of dividend warrants issued during the half year ending the 5th of January, 1833, that they amounted in all to about 280,000, and the number has not materially varied in the interval. The large number (87,176) of holders of stock not producing above 5*l.* of half yearly dividend is principally, we believe, ascribable to the circumstance of the Bank of England and the London private banks not allowing interest on deposits.

We may observe, by the way, that the number of persons having a direct interest in the funds is much greater than it would appear to be from this account. The dividends upon the funded property belonging to the Bank of England and other banks, to the Equitable and other insurance companies, &c., are paid upon single warrants, as if they were due to so many private individuals; whereas they are really paid to these individuals only because they act as factors or trustees for a vast number more. It is, consequently, quite absurd to pretend, as is sometimes done, that any interference with funded property would affect only 280,000 individuals out of a population of 25,000,000. Any attack upon the dividends would really be destructive, not merely of the interests of those to whom dividend warrants are issued, but of all who depend on them: it would destroy our whole system of banking and insurance, and overspread the country with bankruptcy and ruin. Not only, therefore, is every proposal for an invasion of the property of the fundholders bottomed on injustice and robbery, but it would, were it acted upon, be little less ruinous to the community than to the peculiar class intended to be plundered.

I. STATE of the Public Funded and Unfunded Debt of Great Britain and Ireland, and the Charge thereon, on the 5th January, 1841.

† Dividends payable 10th of October.

‡ Dividends payable on 5th of January.

NATIONS, LAW OF. *See* Law.

NATI'VITY. A word used by way of eminence to signify the birthday of our Saviour, and of saints and other canonized persons. In Astrology, the word nativity is synonymous with *horoscope*, which see.

NA'TRIX. The subgenus of the Linnæan *Colubri*, of which our common harmless snake, *Coluber natrix*, Linn., is the type.

NA'TROLITE. A mineral which occurs in small rounded fibrous masses of a yellowish colour; it is by some called *prismatic zeolite*. It is chiefly found in Suabia in amygdaloidal basalt. It is a hydrated silicate of soda and alumina.

NA'TRON. The German name applied to soda; hence, also, the German chemists call sodium *natrium*. It is probably from the ancient term *νιτρον*, *nitron*, or fossil alkali; hence *nitre*. It is found in sandy soils of various countries, but more especially in Egypt, where it was anciently employed to a great extent in the art of embalming. *See* Mummy.

NA'TURAL. In Music, a character marked thus ♮, whose office is to contradict the flats or sharps placed at the beginning of a stave or elsewhere, and by the use of which the note to which it is prefixed returns to the diatonic scale.

NA'TURALIZATION. In Law, the process by which an alien is placed in the same civil condition as if he had been born under the dominion of the state. In England, this can only take place by act of parliament; and it is provided by stat. 1 G. 1. c. 4. that no bill for naturalization can be received without certain clauses incapacitating the party from sitting in parliament, or being a member of the privy council, &c. *See* Alien.

NATURAL HISTORY, may be defined to be the history and description of the natural products of the earth, whether minerals, vegetables, or animals, together with a scientific development of their causes and effects. The reader will find all the branches of this wide and interesting subject treated at considerable length under their respective heads.

NATURAL ORDERS OF PLANTS, are groups of genera which are supposed to bear a greater resemblance to each other than to any thing else. They may be said to be coeval with our knowledge of plants; for the old ideas of grasses, trees, herbs, corn, fruit trees, indicate a natural perception of the existence of some such groups. When systematical botany first assumed the semblance of science we find the Umbelliferous, Leguminous, Liliaceous, Labiate, and Composite orders, more or less distinctly defined. It is, however, chiefly by the labours of botanists posterior to the days of Linnæus, especially to Jussieu and his followers, that the present improved limitation of natural orders is owing. It must, however, be confessed that they are still in great need of regulation, which can scarcely, however, be anticipated until something precise shall have been settled concerning the relative value of differences in organization. The most

complete account of them in English is that in *Lindley's Natural System of Botany*, ed. 2., in which 289 natural orders are enumerated.

NA'TURAL PHILOSO'PHY, or PHYSICS, is the science which treats of the properties of natural bodies, and their actions on each other. *See* PHYSICS.

NATURE, LAW OF. *See* LAW.

NAU'CA. In Botany, a seed in which the scar of the helum occupies one third part of the external surface, as in the horse chesnut.

NAUMA'CHIA. (Gr. ναυς, *a ship*, and μαχη, *a fight*.) Among the Romans, a representation of a naval engagement, which took place most usually in theatres (called also naumachiæ) made especially for the purpose. These exhibitions were originally instituted for purposes of naval discipline; but, in process of time, only malefactors or captives whose lives had been forfeited participated in them. They appear to have been conducted on a scale of such magnificence as almost to exceed belief. Within the places set apart for them whole fleets went through their evolutions without inconvenience or confusion, and all the appliances of human ingenuity were put in play to give an air of reality to the representation. We are told by Suetonius that in an exhibition of this sort given by Nero sea monsters were seen swimming about in the artificial lake; and in the sea-fight on the lake Fucinus, given by Claudius, there are said to have been no fewer than 19,000 combatants. Julius Cæsar appears to have first given a naumachia on an extensive scale: his example was followed by many of his successors on the imperial throne; and at last they were frequently exhibited at the expense of private individuals, as a means of increasing their popularity. The seats for the convenience of spectators were arranged in a manner somewhat similar to those in the amphitheatres. *See* AMPHITHEATRE.

NAU'SEA. (Gr. ναυς, *a ship*.) A sensation of sickness, similar to that produced by the motion of a ship at sea. An inclination to vomit.

NAUTILI'DÆ. (Gr. ναυτιλος, the name of the argonaut in Aristotle.) The family of Cephalopods with siphoniferous shells, of which the *nautilus* is the type.

NAU'TILUS. (Gr. ναυτιλος.) The name of a genus of Tetrabranchiate Cephalopods, including those which have a chambered shell with simple septa, perforated in the centre, concave towards the outlet of the shell, and with the last chamber the largest, and containing the body of the animal.

NA'VAL ARCHITECTURE. In the small space we can assign to this subject we shall merely endeavour to convey a general notion of the principles and process of construction.

Ships are built in different forms, according to the service they are intended for and the burdens they have to carry. It is in men-of-war, which, besides possessing in an eminent degree the general qualities of a ship, have to support a heavy armament of cannon, and which are destined to severe and long-continued service, that the principles of construction have been carried to the greatest perfection. The form of the ship, her strength, or the scantling necessary for the services required of her, are, from our imperfect knowledge of hydrodynamics, the results of experience alone.

When a ship is to be built, her form is projected in three different planes perpendicular to each other.

1st. The *sheer draught*, which is the side view, or projection on the plane of the keel. On this are laid off the length, the heights of all the parts from the keel, the position and rake of the stem and sternpost, the principal frames or timbers of the sides, the ports, decks, channels, place of the greatest breadth or midship frame, stations of the masts, &c.

The frames before the midship frame are distinguished by letters; abaft it, by numbers.

The midship frame is not exactly in the middle of the length, but rather before it.

2d. The *body plan*, or end view. This shows the contour of the sides of the ship at certain points of her length; and since the two sides are exactly alike, the left half represents the vertical sections in the after part of the body, and the right hand half those in the fore part. The base of the projection is the midship, or largest section, called also the *dead flat*, within which the other sections are delineated. On this are exhibited also the beams of the decks.

3d. The horizontal or floor plane, called also the *half breadth plan*. The base of this is the section made by the horizontal surface of the water and the outside surface of the ship, and is called the *upper water line*, or *load water line*. If the ship now be supposed to be lightened uniformly, she will exhibit another water line, and thus any number of like parallel sections at equal distances down to the keel.

On this projection the water lines appear as curves, on the sheer draught as straight lines parallel to the keel.

These three sections correspond to each other upon the same scale; and any point in one is immediately referable to the other two projections.

The several parts are drawn from these plans in their full size on the floor of the mould loft, and worked from the moulds or models so taken.

The place in which the ship is built is called a *slip*. In the middle, and leading to the water, is a row of piles of stout pieces of wood called the *blocks*, having a declivity towards the water of about 1 inch in 1 foot. On these the keel, which is of elm, is laid, and its component lengths scarfed together. Under the keel is placed the false keel for defence. At the end furthest from the water is raised the *stem*, which is in fact the keel continued upwards. Inside the stem, and just above the keel, is the *apron*, a curved timber connecting both. On each side of the upper part of the stem is fixed an upright timber; these are called the *knight heads*, and the bowsprit lies between them. At the other end of the keel is the sternpost, at which the planking finishes abaft, and on which the rudder is hung. Inside (or before this) are the *inner post* and other pieces for strength. Upon the keel is fixed a layer of timber of the same breadth, and rising forward and aft, called the *dead wood;* on this are placed the *floor timbers:* these consist of one which crosses the keel to which it is coaked, and the two parts of a like timber firmly joining it, and projecting beyond its ends. The several pieces are got into their places by shifting shears.

The *frames* consist of pairs of timbers composed of pieces of different lengths, joining the floor timbers, and carried upwards. The length joining the floors is called the first futtock, the next the second futtock, and so on, ending in the *top timbers*. The pairs are bolted by iron bolts; and of late adjacent pairs have been thus connected. The frames are supported temporarily by being fixed to the *cross spalls*,— long fir planks laid horizontally about the height of the gun deck.

Those frames whose planes are perpendicular to the keel are called *square frames;* at the head and stern these planes incline towards the extremities, and are called *cant frames*. These divisions of the ship are called accordingly *square* and *cant bodies*.

When the framing has assumed its form the *ribands* are fixed; these are thick narrow planks at wide intervals, extending the length of the vessel, marking the direction of the planks; they are firmly shored, and removed when the planking comes on. The *riband lines* appear on the half breadth plan as diagonal lines.

Upon the keel, and over the floor timbers, to which it is scored, is laid the *kelson*, which is, in fact, a second keel over the first.

The stern of square-sterned ships is formed upon the *wing transom;* the uppermost of the horizontal pieces of timber called *transoms* crossing the sternpost inside.

The wing transom is secured to the timbers of the side by a strong horizontal knee.

When the framing is complete, the outside planking is laid on. The *wales*, thick planks above the water, are first secured to the ribs. The *clamps* are thick planks inside, to support the ends of the beams of the decks.

The *beams* support the decks, rest on the clamps, and are secured to the side by *knees*.

The *breast hooks* are strong curved pieces of timber crossing the stem, and joining the bows. The *deck hooks* are the same, being at the decks. The *crutches* answer a like purpose below in the after part.

The *port sills* are the upper and lower edges of the ports.

The *spirketting* is the plank of the side between the water way and the port sill.

The *chain wales* are thick planks of the outside to receive the chains and preventer bolts for the support of the rigging.

The *foot waling*, or *ceiling*, is the plank lining the inside of the ship below.

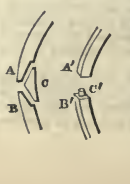
The *limber boards* are short thick pieces of wood resting against the kelson for the convenience of keeping a clear passage to the well.

The *knee of the head*, also called the *cutwater*, is the projecting part of the head; it is secured to the bows by knees called *cheeks*.

In order to bend wood into the necessary curvature it is steamed in places for the purpose. When the planking is all complete, the ship is caulked and painted.

The fastenings of timber are effected by bolts, treenails, or coaks. The present method of framing ships of war is chiefly due to Sir Robert Seppings. We shall describe it here generally: for particulars, see the *Phil. Trans.* 1814, and the published reports on the subject.

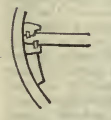
As the timbers or ribs cannot be procured entire, or of the proper curvature, various methods have been used for joining the several pieces together. A method used till lately consisted of an angular chock C, fastened by treenails to the ends A B of the timbers. By this plan all stress upon the joint, in whatever direction, falls on the treenails; and when the chock decays, no support is afforded in any sense whatever.



At present the square ends, A′ B′, are brought together, while a *coak* C′, or small oak cylinder, is let into each.

By this plan the two faces resist any effort by pressure from without to close the timbers, and the coak itself resists the effort (perpendicular to this last) to make one timber slide past the other by the whole force necessary to cut it off flush with the section. In the single case of lifting one face exactly perpendicularly off the other, the coak offers no resistance; this effort, which is that produced by the strain of the rigging on the sides, is opposed by other numerous connections. The method is very ancient, being used in the construction of the pillars in the temple at Balbec; the advantage of its application to shipbuilding is seen in the frames, which undergo no change of form while hoisting into their places. The efficiency of the plan, however, does not appear in a single length, but in the system of frames, each joining of which is placed near the middle of the next piece.

A *shelf piece*, coaked and bolted to the timbers or ribs, and resting on short vertical pieces of timber called *chocks*, and sometimes scored to the ribs, is carried like a hoop entirely round the ship. On this the beam ends are coaked; and over these again is laid a strong water way scored to the beams, and coaked. Besides these the beam end is clasped by two arms of an iron knee, of which the third, which is vertical, is bolted to the chock.



The shelf binds firmly the ends and sides of the ship together, and resists like an arch all external pressure.

The spaces between the timbers below are filled up by dry wood driven in tight, and caulked, thus rendering the bottom solid and water-tight, independently of the planking.

One of the most important improvements is the diagonal framework below. Instead of the former planking in the hold are placed *braces*, crossing the ribs, to which they are coaked, at an angle of 45°; those in the fore body incline (or rake) aft, and those in the after body forward. They butt against the kelson, and extend nearly to the water; they are in general placed under every other beam, but closer at the extremities.

Longitudinal pieces of timbers are laid nearly parallel to the keel over the heads or joinings of the timbers, and bolted through; these, crossing the diagonals, form a series of rhomboidal figures, across which, inside, are firmly driven *trusses*, lying the opposite way from the diagonals: these are bolted through, and, when necessary, are further tightened by driving in thin iron plates at the ends. The diagonals act by the *tension* of the fibres, the trusses by the *thrust*, and the whole thus resists every effort to change the figure of the ship.

The system was first put into complete practice in the Tremendous, 74, in 1810; which ship evinced, in several severe trials, a firmness and dryness not known before.

M. C. Dupin has shown (*Phil. Trans.* 1817) that the principle of diagonal framing had suggested itself, and been tried by several French engineers, but as often abandoned. The merit, therefore, of Sir R. Seppings, in reducing to practice a system which to others had been attended with insuperable difficulties, more than compensates the want of novelty in the idea itself.

The ancient square, massive, but weak sterns, have been replaced by Sir R. Seppings by round sterns, corresponding in construction, and therefore in strength, to the bow. These have again undergone various alterations, tending to combine the strength of the new with the imposing appearance of the former stern.

It is only now by contrasting the solid and immoveable frame with the former weak and unconnected structure, that we can fully perceive the inefficiency of the ancient construction. The timbers, instead of forming an independent system, were often supported in part by the planking itself, as is the case in boats. The masts, resting only upon their steps, instead of strong platforms which diffuse the pressure on all sides, and pressed downwards by their weight, and by the enormous strain of the rigging, arising from the wind on the sails, forced the keel down, and made the ship leaky. The timbers and framework, being at right angles, without mutual support, the whole stress of the ship came on the fastenings; and, lastly, the safety of the ship depended entirely upon that of the outside plank, the part most exposed to injury.

The planks of the decks have also sometimes been placed diagonally; and lately iron diagonal straps have been added to the upper works inside.

The extremities being unsupported below by the water droop, or the ship *hogs*, a three-decker formerly drooped at once, on being launched, 9 inches at each end, which increased with her length of service; at present, such a ship droops only $3\frac{1}{2}$ inches, which, when the materials are set, suffers little or no increase.

Within the last few years considerable changes have been made by Sir W. Symonds in increasing the beam of the ships, and therefore their stability, and otherwise in the forms. Several improvements have also been introduced by Sir O. Lang.

Exposure to moisture being a cause of the decay of timber, building under cover has long been practised. This also protects the men from the weather.

The wood usually employed in shipbuilding is oak. Elm, which does not split readily, is employed for the keel, and for the caps. East India teak, a very heavy durable wood, which does not shrink, nor is liable to splinter from shot, is now very much used. African teak is also much used. Fir is used for light works, masts, &c.

The bottoms of ships are liable to become covered with weeds and shells, and to be eaten through by worms. To prevent these evils, the bottoms were formerly covered with a thin sheathing of wood, which was replaced when worn. Lead has also been used. Ships are now sheathed almost universally with thin sheets of copper.

For further information on this subject, reference may be made to the following works: — Bouguer, *Traité du Navire;* Clairbois, *Traité Elementaire, &c.*; *Chapman's Naval Archit.*, with Notes by Dr. Inman; *Steel's Elements*, with an Appendix by J. Knowles, F.R.S.; *Fincham's Outlines of Shipbuilding;* the article "Shipbuilding" in the new edition of the *Ency. Britannica*.

NAVAL CROWN. Among the Romans, a crown of gold or silver, resembling the prow of a ship, awarded to him who first boarded a hostile vessel. *See* CROWN.

NAVE. *See* NAOS.

NAVE. In Mechanics, the middle part of the wheel, from which the spokes radiate.

NAVIGA′TION (Lat. navis, *a ship*), is that branch of science by which the mariner is taught to conduct his ship from one part or place to another.

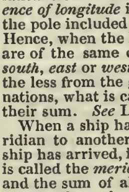
To understand the principles of navigation, and their practical application, it is necessary that the mariner should be acquainted with the form and magnitude of the earth, the relative situations of the lines conceived to be drawn on its surface, and have charts of the coasts and maps of the harbours which he may have occasion to visit. He must also understand the use of the instruments by which the direction in which a ship is steered and the distance which she sails are ascertained; and be able to deduce from the data supplied by such instruments the situation of his ship at any time, and to find the direction and distance of any place to which it may be required that the ship should be taken.

A curve passing through any two places on the earth, and cutting every intervening meridian at the same angle, is called a *rhumb line;* the angle which such a curve makes with each meridian is called the *course* between any two places through which the curve passes; and the arc of that curve intercepted between any two places is called their *nautical distance*. This distance is more than that measured on the arc of a great circle passing through the two places, unless both places are on the same meridian, or both on the equator, when the rhumb line and great circle coincide.

The *difference of latitude* between any two places is an arc of a meridian intercepted between the parallels of latitude on which the places are situated; and the *difference of longitude* is the arc of the equator, or the angle at the pole included between the meridians of the places. Hence, when the latitudes or the longitudes of two places are of the same denomination with respect to *north* or *south*, *east* or *west*, the difference is found by subtracting the less from the greater; but when of different denominations, what is called their difference is found by taking their sum. *See* LATITUDE, LONGITUDE.

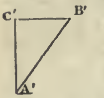
When a ship has sailed on a rhumb line from one meridian to another, the arc of the parallel at which the ship has arrived, intercepted between the two meridians, is called the *meridian distance* which the ship has made; and the sum of all the intermediate meridian distances, computed on the supposition that the distance sailed on the rhumb line is divided indefinitely small equal parts, is called the *departure*.

In the annexed diagram, let P represent the north pole; D E an arc of the equator; P D, P F, P G, and P E meridians, and A B a rhumb line passing through A and B; A S, K H, L I, and B C, arcs of parallels of latitude at the points A, H, I, and B respectively; and let A H, H I, I B, &c. be so small and so numerous that neither they nor A K, K H, H O, I O, &c. may differ sensibly from straight lines. Then if a ship sail from A to B, B C is called the meridian distance; if from B to A, A S is called the meridian distance; and in either case the sum of K H, O I, N B, is called the *departure;* and A K + O H + I N, &c., which is always equal to A C or B S, is the *difference* of latitude.



Now, A K H, O H I, N I B, &c., may be considered as identical right-angled plane triangles; and if in the an-

nexed plane triangle, right-angled at C′, A′ B′ be taken equal to A B in the preceding figure, A′ C′ to A C, or to its equal A K + H O + I N, and the angle B′ A′ C′ to B A C, or O H I, or N I B, then C′ B′ in this figure would accurately represent K H + O I + N B, &c. in the preceding one. That is, in the plane triangle A′ B′ C′, right-angled at C′, if A′ represent the course from one place to another, A′ B′ the distance of the two places measured on the rhumb line passing through them; then A′ C′ will be their *difference of latitude*, and C′ B′ the *departure* made in sailing from the one to the other.



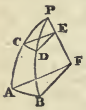
On these principles depend what is called *plane sailing;* and it is evident that if any two of the four elements, *course*, *distance*, *difference of latitude*, and *departure*, be given, the others may be found by the resolution of a right-angled plane triangle. The formulæ are,

$$\begin{aligned} \text{dep.} &= \text{dist.} \times \text{sin. course}, \\ \text{diff. lat.} &= \text{dist} \times \text{cos. course}, \\ \text{dist.} &= \text{dep.} \times \text{cosec. course}, \\ \text{dist.} &= \text{diff. lat.} \times \text{sec. course}, \\ \text{tan. course} &= \frac{\text{dep.}}{\text{diff. lat.}}. \end{aligned} \qquad \text{(A.)}$$

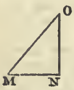
When a ship sails on a meridian, the diff. lat. is the same as the nautical distance, and the *latitude* only, not the longitude, is changed; and when a ship sails on a parallel of latitude, the departure is the same as the nautical distance, and the *longitude* only, not the latitude, is changed: but in sailing in any other direction, both the latitude and longitude are changed.

For finding the change of latitude corresponding to any course and distance, the principles of plane sailing, already explained, are sufficient; but to find the change of longitude corresponding to any given change of place requires considerations of a different kind.

Let a ship sail on a parallel of latitude, as from C to D, and let P C A, P D B, be two meridians passing through C and D, and meeting the equator in A and B; then A B, or the angle A P B, is the difference of longitude, corresponding to the distance C D sailed on the parallel in the latitude A C or D B. And if F be the centre of the sphere, A F B, C E D, portions of the planes of the equator and parallel respectively, we have, by similar sectors, C D : A B : : D E : B F : : cos. lat. : rad. : : 1 : secant of lat.; therefore A B = C D sec. lat.



Hence, again, if in the annexed plane triangle M N O, right-angled at N, the angle M be made equal to the number of degrees and minutes of the latitude of the parallel on which the ship is sailing, and M N be equal to C D, MO in this figure will be equal to the arc A B in the preceding one, and will consequently represent the difference of longitude; for



$$\text{M O} = \text{M N sec. M} = \text{C D sec. lat.}$$

Therefore, in sailing on a parallel, the properties which connect the latitude of the parallel, the distance sailed upon it, and the corresponding diff. long. are all found in a right-angled plane triangle; the base representing the distance sailed on the parallel, the hypotheneuse the diff. long., and the included angle the latitude of the parallel.

When a ship sails on an oblique rhumb, two methods have been proposed for connecting the other elements with the diff. long.: one called the *middle latitude* method; and the other, from the name of its inventor, *Mercator's sailing.*

Middle latitude sailing is a compound of plane and parallel sailing. Referring to the first figure in this article, it is evident that K H is greater than C M, but less than A Q; that O I is greater than M N, but less than Q R; and that K H + O I + N B will not differ greatly from the meridian distance midway between the parallels C B and A S.

The departure corresponding to course c, and distance d, being therefore found from dep. $= d$ sin. c, and this being taken as a meridian distance in the latitude $\frac{1}{2}(l + l')$, the middle latitude between the latitude l sailed from and that l' arrived at, the diff. long. is found approximately from the principles of parallel sailing, from the formula,

$$\text{diff. long.} = \text{dep. sec.} \tfrac{1}{2}(l + l').$$

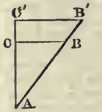
From this, and from the first and last of the formulæ (A.), we immediately deduce the following for middle latitude sailing, viz.:—

$$\begin{aligned} \text{diff. long.} &= \frac{\text{dist.} \times \text{sin. course}}{\text{cos. mid. lat.}} \\ \text{tan. course} &= \frac{\text{diff. long.} \times \text{cos. mid. lat.}}{\text{diff. lat.}} \\ \text{dep.} &= \text{diff. long.} \times \text{cos. mid. lat.} \end{aligned} \qquad \text{(B.)}$$

In *Mercator's sailing* the globe is conceived to be extended from the equator towards the poles, so as to form a cylinder whose diameter is that of the equator; the corresponding elementary parts of the meridians and parallels, as projected on the cylindric surface, bearing the same proportion to each other as the like corresponding parts do on the spherical surface; the projected rhumb lines being straight lines, and the poles vanishing in infinite distance. Such a cylinder, unrolled on a plane, is called a *Mercator's chart*. Now, considering the earth as a sphere, the meridians and the equator are equal great circles, and therefore any small portion of a parallel is to a like portion of the meridian in the same proportion as the radius of the parallel to the radius of the equator; that is, as the cosine of the latitude to the radius of the tables, or as radius to the secant of the latitude. If, therefore, m represent the length of an elementary portion of the meridian at latitude l, and m' be the projection of m on Mercator's chart; then, generally, $m' = m$ sec. l.

It follows from this that in Mercator's projection the degrees of latitude, which at the equator are equal to those of longitude, increase with the distance of the parallel from the equator proportionally to the secants of the latitudes. The parts of the meridian thus increased are called *meridional parts;* and it is a property of the projection that the meridional parts of any given latitude are equal to the sum of the secants of the minutes in that latitude. (*See* MERCATOR'S CHART.) The sum of the secants being computed for every minute up to any latitude l, and tabulated, forms what is called a table of *meridional parts;* and the difference, or the sum of the meridional parts corresponding to the latitudes of any two places, is called the meridional diff. lat. of those places, the *difference* being taken when the latitudes are of the *same*, and the *sum* when of *different* denominations.

It is likewise a remarkable property of Mercator's projection, that any small triangle on the sphere is represented on the chart by a similar triangle, the angles of the original triangle and its representation being equal. Hence the ship's path on the sphere and its projection on the chart cut the meridians under the same angle. If, therefore, A B C be a triangle on the sphere, A C being a portion of the meridian, and A B′ C′ its projection; then A B′ and A C′ will be in the same direction with A B and A C, and B′ C′ will be parallel to B C. In these triangles, therefore, the course A is an angle common to both; A C is the diff. lat., A C′ the meridional diff. lat., C B the departure, C′ B′ the diff. long., A B the distance run, and A B′ the distance as projected on the chart, the same scale being used for measuring all the lines in the diagram. Hence, from such parts of these triangles as may be determined by observation, or taken from tables, the others may be computed.



The following formulæ are obvious consequences of this construction:—

$$\begin{aligned} \text{diff. long.} &= \frac{\text{dep.} \times \text{mer. diff. lat.}}{\text{diff. lat.}} \\ \text{tan. course} &= \frac{\text{diff. long.}}{\text{mer. diff. lat.}} \\ \text{distance} &= \text{diff. lat.} \times \text{sec. course.} \end{aligned} \qquad \text{(C.)}$$

The course of a ship at sea is determined by the *compass* (for the description of which *see* COMPASS). The needle generally rests in a position pointing northerly and southerly; and the angle which its direction makes with the true north and south line is called the *variation of the compass*, the variation being denominated *easterly* or *westerly*, according as the north end of the needle is to the east or west of the true north. The amount of this deviation differs greatly in different situations; and it is by no means a constant quantity even at the same place. There are, however, simple astronomical means of finding it at any place; so that, by applying a correction for the variation, either the true course may be gained from an observed compass one, or the compass course from a computed true one.

Besides the general *variation* to which we have here adverted, it is found that in ships which have large masses of iron on board, the compass is sensibly attracted, and the effect varies with the direction of the ship's head. Mr. Barlow has devised a remedy for this cause of derangement, which consists in placing a small disk of iron in such a situation behind the compass that its single effect exactly counterbalances the combined force of the more distant masses. *See* MAGNETIC COMPENSATOR.

The velocity of the ship, or the *rate* of sailing, is determined experimentally, at the end of every hour, by heaving the *log*. (*See* LOG.) For changes of velocity between the times of heaving the log, the officer on duty makes the best estimate he can.

When the wind is adverse or changeable, it is often requisite to sail on different courses; and the crooked line which the ship then describes is called a *traverse;* and the method of finding a single course and distance equivalent to such a compound one is called *resolving a traverse.*

This may be done by a geometrical projection, but it is generally effected in practice by the aid of the traverse table. From this table the *diff. lat.* and *dep.* corresponding to each course and distance is taken, and entered in an appropriate table, having columns headed N. S. E. W.; namely, N. and S. for diff. lat., and E. W. for departure. The difference between the sums under N. and S. shows the diff. lat., as does the difference between the sums under E. and W. the departure; and in either case the difference is of the same denomination as the larger sum. The course and distance required are then either found by inspection in a traverse table, or by the formulæ (A.).

When a ship makes considerable way through the water, and the wind is on the beam, abaft it, or even a little before it, she generally moves forward in the direction of the fore and aft line; but in rough weather, with the wind forward, she will generally be driven more or less to leeward, as will be shown by the direction of the wake, or the ripple formed by the waves closing behind her. The angle which this ripple makes with the direction of the keel is called the *leeway;* and it must be applied as a correction to the course shown by the compass, and always allowed *from* the wind, — that is, to the left, if the wind is on the right-hand side of the ship, and to the right, if on the left. *See* LEEWAY.

All matters relating to the navigation of a ship are entered in a systematically ruled book, called the *log-book;* and what day after day is so recorded is called the ship's journal. The principal columns in the log-book are for the hour of the day, the course, rate of sailing, leeway, and winds; one for general remarks, and for entering the particulars and results of celestial observations, for notes on the weather, and memoranda as to all important points of duty in the ship, the sails set, and the manner in which the crew are employed. To this is daily appended the latitude and longitude of the ship at noon, both as deduced from celestial observations, and as computed from the course and distance since the time when the place was last ascertained. The place determined from the course and distance is called the place by *dead reckoning*. The bearing and distance of the land first expected to be seen, and the course and distance made on the whole, during the day, are also added.

If the course and distance could always be accurately determined, the place of the ship could be computed with corresponding exactness from the principles of which we have above given a concise account. But these data can only be obtained in a roughly approximative form. The effect of unknown currents, unavoidable imperfections in steering, and numberless other sources of error, render the place of the ship, as estimated from the reckoning, very doubtful; and, in fact, when the mariner is obliged to rely for several days on these data only, he often finds that his expected and his true place are considerably distant from each other.

In the modern practice of navigation, therefore, the course and distance are only used to enable the seaman to assign approximately the place of his ship between the times at which it is determined, independently, by celestial observations.

This branch of nautical knowledge, which is generally and properly included in every system of navigation, is called *nautical astronomy;* and the improvements which have been introduced in its modern application constitute the chief difference between navigation as practised in our own and former times.

For a minute explanation of the processes by which the place of a ship on the wide ocean may be determined, from the observed situation of celestial objects with respect to each other and to the horizon, we must refer to works expressly devoted to the subject. But we shall give a short account of the most useful practical methods of finding the *latitude*, the *longitude*, and the *variation of the compass*, which are the three principal problems in nautical astronomy.

Reduction of Altitudes. — Before the altitudes of celestial objects as observed at sea can be employed in the solution of astronomical problems, they must be corrected for the effects of dip and parallax; and for semidiameter, when the altitude of the upper or lower border, instead of that of the central, has been observed, as in the case of the sun or moon.

If $A =$ the altitude of the upper or lower border, $s =$ the semidiameter, d the dip of the horizon (that is, the angle through which the sea horizon appears depressed in consequence of the elevation of the observer), r the refraction corresponding to the alt. A, and p the horizontal parallax taken from the *Nautical Almanac* for the time of observation, and $A' =$ the true altitude: then

$$A' = A - d \mp s + p \cos. (A - d \mp s) - r.$$

In practice, the corrections to be applied to A to obtain A′ are taken from tables, and the process of reduction is short and simple.

To find the latitude from the observed meridian altitude of a known celestial object: —

Let z be the complement of the true altitude, as deduced from the observed one, D the object's declination, and L the latitude; and call z north when the zenith is north, and south when it is south of the object: then $L = z \pm D$; a formula in which D is + when z and D are of the same, and — when of different denominations, and L is of the same denomination as the greater of z and D.

To find the latitude from two observed altitudes of the sun, with the time elapsed between the observations: —

Let $t =$ the half elapsed time in degrees, p the sun's polar distance at the middle instant between the observations, $s =$ half the sum, and $d =$ half the difference of the two corrected altitudes; then compute the angles A, B, C, D, and E, in succession, from the following formulæ: —

$$\sin. A = \sin. t \cdot \sin. p.$$
$$\cos. B = \sec. A \cdot \cos. p.$$
$$\sin. C = \text{cosec.} A \cdot \cos. s \cdot \sin. d.$$
$$\cos. D = \sin. A \cdot \sin. s \cdot \cos. d \cdot \sec. C.$$
$$E = B \mp D.$$

And the expression for the latitude is,

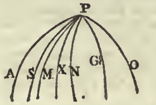
$$\sin. \text{lat.} = \cos. D \cdot \cos. E.$$

There are many other methods by which the latitude may be found, but the two which we have given are those most generally used by seamen.

We pass on to a consideration of the principles on which the methods of finding the longitude astronomically at sea are founded.

The longitude is found by comparing the *time* at the first meridian with the *time of the same denomination* at the place of observation, allowing 15° of longitude for every hour in the *difference* of the times.

In the annexed diagram, let P A represent the meridian passing over the first point of *Aries*, P S that passing over the true and P M that passing over the mean place of the sun, and P X that passing over any other celestial object X. Let also P G be the meridian of Greenwich, P N a meridian in *west* longitude, and P O a meridian in *east* longitude.



Then, for that instant of absolute time, A P G represents the *sidereal*, S P G the *apparent*, and M P G the *mean* time at Greenwich; twenty-four hours of time being represented by four right angles. A P N, S P N, and M P N, are the sidereal, apparent, and mean time at the meridian P N; and A P O, S P O, and M P O, the like times at the meridian P O.

Now N P G, the longitude of the meridian P N, = A P G − A P N = S P G − S P N = M P G − M P N; and G P O, the longitude of P O, = A P O − A P G = S P O − S P G = M P O − M P G.

Therefore, the longitude of any place represented in time is equal to the difference of the relative times at the first meridian and the meridian of the place; the times being both sidereal, both apparent, or both mean time, and both reckoned from the same noon, — *west* when the Greenwich time is *greater*, and *east* when it is *less* than the time at the place of observation.

The angle X P G, reckoned westerly from P G, is called the meridian distance of the object X from the meridian P G, and X P N its meridian distance from the meridian P N. A P X is its right ascension, A P S the right ascension of the sun, and S P M the *equation of time*, or the difference between mean and apparent time.

Now, if a be the altitude of an object X, as observed in a given latitude l, say on the meridian P N, and $p =$ P X, its polar distance; then, if we put $s = \frac{1}{2}(a + l + p)$, the angle X P N may be determined from this expression,

$$\sin.^2 \tfrac{1}{2}(XPN) = \sqrt{[\sin. (s - a) \cdot \cos. s \cdot \sec. l \cdot \text{cosec.} p.]}$$

And X P N + A P X − A P S $\pm$ S P M = M P N, the mean time at the meridian P N.

P X, A P X, A P S, and S P M, are furnished by the *Nautical Almanac;* and it is evident, therefore, that from an observed altitude of a celestial object, with the data supplied by the *Nautical Almanac*, the *mean time* at the place of observation may be found.

With respect to the corresponding Greenwich time, it may be found by means of a chronometer, whose error and rate are ascertained before it is taken to sea. For example, if on May 4th the chronometer be 4 m. fast for Greenwich time, and on May 14th 4 m. 50 s. fast for Greenwich time; then, if on May 30th, at sea, an altitude be observed to determine time at the place of observation, when this chronometer shows 5 h. 46 m. 12 s., then the true mean time at Greenwich is 5 h. 40 m. 2 s.; and if the mean time at the place deduced from the observation be 3 h. 57 m. 48 s., the longitude of the place will be 5 h. 40 m. 2 s. − 3 h. 57 m. 48 s. = 1 h. 42 m. 14 s. = 25° 33′ 30″ *west*.

The Greenwich time may also be found by considering the moon in the heavens as the pointer of a Greenwich clock, and her distances from the sun and certain stars as indicating the Greenwich times to which they cor-

respond. These distances are computed, and published beforehand in the *Nautical Almanac*, for every third hour of Greenwich time; so that if at any moment we ascertain the moon's distance from some such celestial object, the Greenwich time may be found by comparing that distance with those in the *Nautical Almanac*.

The distances there given, however, are the distances of the objects as seen from the centre of the earth; and therefore before a distance observed on the surface can be made available for finding the Greenwich time, it must be reduced to what it would have been if the observation had been made at the centre. Many formulæ have been devised, and numerous and extensive collections of tables have been formed, to assist in making this reduction; but perhaps the following is as convenient as any other that has been proposed.

Let m be the moon's app. zenith dist., s the sun's; M the moon's true zenith dist., S the sun's; d the app. dist. of the centres of the objects, and D the required or the true distance, and put

$$A\ \tfrac{1}{2}(M+S),\ B = \tfrac{1}{2}(m+s+d)-d,$$
$$\sin.X = \sqrt{(\text{cosec.}\,s\cdot\text{cosec.}\,m\cdot\sin.M\cdot\sin.S\cdot\sin.A\cdot\sin.B)}$$
$$\text{then } \sin.\tfrac{1}{2}D = \sqrt{[\sin.(A+X)\ \sin.(A-X)]}.$$

To compute the bearing of the sun, the altitude, polar distance, and latitude being known:—

Let a = the altitude, l = the latitude, p = the polar distance, $S = \frac{1}{2}(a+l+p)$, and B the required bearing, or azimuth — estimated from the south when the latitude is north, and from the north when the latitude is south; towards the east when the altitude is increasing, and towards the west when it is decreasing, then

$$\sin.\tfrac{1}{2}B = \sqrt{[\sec.a\cdot\sec.l\cdot\cos.S\cdot\cos.(S-p)]}.$$

If the compass bearing of the object be observed when the altitude is taken, the variation of the compass may hence be found; for let B′ = the compass bearing; then the variation is B + B′ or B—B′, the sign + being used when one bearing is eastward and the other westward, and — when both are on the same side of the meridian; and the variation is *west* when B is to the *left*, and eastward when it is to the right of B′.

For an account of the history of navigation, the reader is referred to the Introduction to *Robertson's Elements of Navigation*. Of modern works on this subject in general use among British seamen, we may notice those by Dr. Inman; and particularly those of Mr. Riddle and of Lieut. Raper, treating both of the theory and practice. The Epitomes of Moore, Mackay, and Norie are also very useful compilations, and have long had an extensive circulation.

NAVIGA'TION ACTS. Several statutes of our early kings were passed with a view to confine particular branches of the English carrying trade to English merchants; but as they were generally enacted merely for some temporary object, they produced little effect. In 1650 the first navigation act was framed under the republican government; partly with a view to punish the inhabitants of the sugar islands, who were chiefly loyalists, partly in hostility to the Dutch. It prohibited foreign vessels from trading to the English colonies (a prohibition extended, in 1651, to the mother country), without a licence from the council of state. In 1660 the government of Charles II. re-enacted these prohibitions on a more extended scale. The chief articles of the act 12 Car. 2. c. 18. are, that no goods be carried to or from any English colonies but in vessels built within the English dominions, or really the property of Englishmen, and whose masters, and at least three fourths of the crew, are English; that no goods of foreign growth or manufacture (with specified exceptions), be imported in English vessels, except from the country where they are grown and manufactured; that sugar, tobacco, and other colonial commodities (thence called in trade enumerated), be imported into no part of Europe but England and her dominions. The history of these acts, so much extolled by British politicians, and termed by some the charta maritima of England, and of the modifications which their provisions have since undergone, especially by Mr. Huskisson's act, 6 Geo. 4. c. 109., is succinctly traced in note xi. of M'Culloch's edition of the *Wealth of Nations*.

NAVI'RE. (Fr.) An order of knighthood instituted by St. Louis, king of France, in 1269, to encourage the lords of France to undertake the expedition to the Holy Land. After having fallen into desuetude, it was again revived, with renewed lustre, in 1448, under the name of the order of the crescent. This order derived its name either from the circumstance that the collars of the knights belonging to it had a ship pendent from them, or because the knights were allowed to bear in their arms a ship argent in chief.

NA'VY (Lat. navis, *a ship*), in its most extended signification is applied both to the mercantile and military marine of a nation; but it is more commonly restricted to vessels of *war* only, all others being said to belong to the merchant service. In treating of the navy, it is usual to consider it under two distinct heads, the *materiel* and *personnel*: the former comprising all that relates to the construction, armament, and equipment of ships; the latter including all who receive rank, pay, or emolument in the service of the navy, and whatever concerns the appointment, station, and duties of officers, sailors, and marines. Under the different heads the reader will find a notice of the chief subjects included in the *materiel* of the navy; and we shall in the present article restrict ourselves to some general remarks respecting its history, management, and present state, which may serve to give a coup d'œil of the whole subject, and which could not well be comprised under separate heads.

The naval history of England is usually divided into three eras; the first comprising all the period that preceded the reign of Henry VIII.; the second ending with the restoration of Charles II.; and the third from the Restoration down to the present time. Omitting all that period of English naval history that intervened between the Conquest and the reign of Henry VIII. as too unimportant to be dwelt upon in a sketch of this nature, we may state, before passing to the second period, that the first ship, properly so called, of the British navy, was built by Henry VII. in the third year of his reign. She was called "The Great Harry," had three masts *, carried 80 guns, measured 138 feet in length, and 36 feet in breadth from outside to outside, and cost upwards of 14,000*l*. This ship constituted the most noble monument of Henry VII.'s regard for the navy; but his designs were matured and perfected by his son Henry VIII., in whose reign England may be said to have first possessed a permanent navy. Previously to his reign our sovereigns had but few ships; when they wished to transport an army to France, or to undertake any considerable naval enterprise, it was usually effected by requisitions of ships and seamen from the different seaport towns of the kingdom, or by hiring them from the merchants of Hamburg, Lubeck, Genoa, &c.; which were dismissed as soon as the occasion for their service was over. But Henry, whose naval force, as in the preceding reigns, was chiefly dependent on foreign auxiliaries, caused several "shippes royall" to be constructed for the service of the state; one of which, the "Regent," measured 1000 tons burthen, and another, the "Marie Rose," measured 500 tons burthen, and carried 700 men. At the conclusion of his reign in Jan. 1547, the verified list of the navy amounted to seventy-one ships and vessels of all sorts, measuring 11,268 tons. During the succeeding reigns of Edward VI. and Mary, the naval force of England diminished considerably, and at the demise of the latter in 1558 amounted only to twenty-six vessels, measuring 7,110 tons burthen. During the long and prosperous reign of Elizabeth which ensued, the navy was greatly encouraged. The naval force collected to oppose the Armada, which consisted of 150 ships with nearly 30,000 men, amounted to 176 sail equipped with about 15,000 men; of these 34 ships with 6,225 men, a larger royal armament than had ever before assembled together, belonged to the crown, the remainder being made up from London, Bristol, Yarmouth, the Cinque Ports, &c. During the last twenty-five years of Elizabeth's reign the navy almost doubled its number; and at her death, in 1603, it amounted to forty-two ships, measuring 17,055 tons, and carrying 8,346 seamen. The reign of James I. was remarkable for the first able and scientific naval architect, Phineas Pett, to whom the art of shipbuilding was indebted for many improvements. "In my own time," says Raleigh, "the shape of our English ships hath been greatly bettered; in extremity we carry our ordnance better than we were wont; we have added crosse-pillars in our royall shippes to strengthen them; we have given longer floares to our shippes than in olden times, and better bearing under water." The striking of topmasts was also invented in this reign; and besides the improved shape of the vessels, Raleigh mentions various minor improvements, adding, "to the courses we have devised studdingsails, spritsails, and topsails; the weighing of the capstan is also new, and the chain-pump and bonnet; we have fallen into consideration of the length of cables, and by it we resist the malice of the greatest winds that can blow." At the death of James I. in 1625, the royal navy consisted of thirty-three ships, measuring 19,400 tons. The navy was first divided into rates and classes under Charles I., who built several new ships in the beginning of his reign, and among others the "Sovereign of the Seas," a larger ship than had ever been built in England, carrying 100 guns, and measuring 1683 tons. But in 1648 Prince Rupert carried off twenty-five ships, none of which ever returned to England; and so reduced was the navy at the commencement of Cromwell's government, that he could muster only fourteen men-of-war, some of them carrying only forty guns. But his vigorous administration speedily raised the navy to a magnitude and power formerly unknown; and under the command of Blake, it became not merely equal but superior to that of the Dutch, then the greatest maritime

* Down to the year 1545, the "Great Harry" was the only ship of that description in the British fleet. She was accidentally burnt at Woolwich in her sixty-fifth year.

power of Europe. It was during the Protectorate that the classes into which Charles I. had first divided the navy were clearly defined, and a regular system established, which has, with little alteration, remained in force down to the present time. At the death of Cromwell in 1658, the navy amounted to one hundred and fifty-seven ships, measuring 21,910 tons, and carrying 50,000 men.

At the restoration of Charles II. in 1660 (from which is dated the third period of English naval history), the whole fleet amounted to only sixty-five ships; but under the able administration of the Duke of York, the royal fleet soon augmented to a fine armament; and though the retirement of the latter, in consequence of his inability to take the Test Act, and the subsequent extravagance of the king, caused the navy to decay, yet such prompt and effective measures were afterwards taken by the Duke, on his recall to office, for its restoration, that at the demise of Charles II. the navy amounted to 179 vessels, measuring 103,558 tons. During the foregoing reign, a remarkable change had taken place in scientific and mechanical operations, and the art of shipbuilding, so long practised on vague and imperfect principles, began to be more highly and extensively developed; for not only were the proportions and qualities of vessels improved, but the mind of the designer was directed to theoretical investigation; and thus, coeval with the third period of naval history, may be justly reckoned the full development of the science of naval architecture. On his accession to the throne James II. continued to evince the same warm interest which, as lord high admiral, he had always manifested for the welfare of the navy. He suspended the navy board, and appointed a new commission, with which he joined Sir Anthony Deane, the best naval architect of the time: four hundred thousand pounds were annually set apart for naval purposes; and so diligent were the commissioners in the discharge of their duty, that on the abdication of James, in 1688, the navy amounted to 173 sail, measuring 101,892 tons, and carrying 6930 guns and 42,003 men. Under the administration of William and Mary, who made little alteration in the system adopted by their predecessor, 99 new ships were added to the fleet; and the celebrated engagement off Cape la Hogue, in 1692, gave the British navy an ascendency over that of France, which it has ever since preserved. Queen Anne at her accession found the navy to consist of 272 vessels, measuring 159,020 tons; but in the third year of her reign a most destructive storm visited this country and the adjacent coasts, by which the navy sustained great damage and loss. No fewer than ten men-of-war were totally lost, and many more were driven on shore and damaged. All measures adding to the strength and efficiency of the navy were exceedingly popular during this reign, and every plan compatible with financial economy was adopted for its benefit; so that though the number of ships was less at the end of Anne's reign, 1714, than at its commencement, the tonnage had increased 8199 tons. During the first four years of George I., large sums were voted for the extraordinary repairs which were required after the long war. A general survey was made of the dockyards and seastores; new dimensions for several classes of ships were established; and at the death of this monarch, in 1727, the navy consisted of 233 ships, measuring 170,862 tons. The navy remained stationary for the first twelve years of the reign of George II.; but on hostilities breaking out with Spain, in 1739, the navy was considerably augmented, and a scale of increased dimensions was established in 1742. In the wars of 1744 and 1755, our naval enterprises were crowned with the most signal success; and at the demise of George II., in 1760, the navy consisted of 412 ships, measuring 321,104 tons, the vote for the naval service of that year being 5,611,508*l.*, 51,645 seamen, and 18,355 marines. The unprecedented progress of the navy during the long reign of George III. is familiar to all. It may be sufficient, therefore, to observe, that though the combined fleets of France and Spain appeared to have an ascendency during the American war, the victories of Rodney restored our previous superiority. The nature of the struggle with revolutionary France, the bitterness with which it was carried on, and the fleets required not merely for the protection of our own shores, but for that of our mercantile shipping and of our numerous colonies in all parts of the world, led to an immense increase of our naval force; and while our navy was thus progressively augmented, the decisive victory of the 1st of June, 1794, followed by those of St. Vincent, Camperdown, the Nile, Copenhagen, and Trafalgar, almost destroyed every fleet that could be opposed to it, leaving us the undisputed masters of the ocean.

From the commencement of hostilities in 1793 to the peace of Amiens, the following table will show the losses sustained both by the English and their enemies, including the ships surrendered to be held in trust.

Loss sustained by the English.		Captured from the Enemy.	
Ships of the line	5	Ships of the line	86
Frigates	13	Frigates	209
Sloops and smaller vessels	41	Sloops and smaller vessels	275
Total	59	Total	570

From the declaration of war in May, 1803, to the general peace concluded in 1815, the number of ships and vessels of war captured and destroyed by the British, with the amount of loss sustained by our fleets during the same period, will be found in the following abstract:—

		Captured.	Destroyed.
French, Dutch, Spanish, Turkish, Danish, American	ships of the line	55	14
	frigates	79	23
	Total	134	37
British	ships of the line	0	0
	under	80	17
	Total	80	17

In the last seven years of the war the British naval force averaged one hundred and forty ships of the line in commission, and five hundred and eighty frigates, sloops, and smaller vessels; those in harbour, ordinary, and building, being estimated at three hundred during the same period. Since the peace of 1815 great improvements have taken place in every department of naval architecture; masts, rigging, sails, ordnance, implements, and instruments, have all undergone revision; alterations, not only in the form and magnitude of British ships, but even in the arrangement of the materials composing them, have been effected; and it is perhaps not going too far to assert, that never at any former period was our navy in a condition better calculated to maintain its long undisputed sovereignty of the ocean.

The following table will show the force of the British Navy at five distinct periods: viz. the year after the breaking out of the French revolutionary war; in 1820, five years subsequently to the peace; in 1830, on the accession of William IV.; on the accession of her present Majesty, in 1837; and in 1840, the date of the last official list:—

Ships, &c.	1793.					1820.					1830.					1837.					1840.				
	In Commission.	Ordinary.	Building.	Total.	Tons.	In Commission.	Ordinary.	Building.	Total.	Tons.	In Commission.	Ordinary.	Building.	Total.	Tons.	In Commission.	Ordinary.	Building.	Total.	Tons.	In Commission.	Ordinary.	Building.	Total.	Tons.
Of the Line	26	84	12	122		14	113	22	149		14	75	18	107		23	59	14	96		28	54	23	105	
Under small vessels	109	82	8	199		113	255	95	464		143	262	64	469		163	219	43	425		149	220	34	403	
Steamers											7	4	1	12		42	11	1	54		65	15	7	87

Classes and Rates.—It is of great importance, in order to insure union in the movements of a fleet and to facilitate the fitting out and repair of ships, that those of the

same rate or class should not differ materially in size or build from each other. Until the Restoration vessels appear to have been "rated" from the complement assigned to each, without any reference to the ordnance they carried; but on the recommendation of a committee appointed in 1745 this method was superseded by classification according to *guns*. In 1793 our ships, which, in consequence of the previous wars, had outgrown their establishments of ordnance, were rated anew at so many guns and upwards; but the latitude of the term "and upwards" giving rise to great irregularities, an investigation took place in 1816, when by an order in council the rule which existed previously to 1793 was revived, and ships were ordered to be rated thenceforth from the number of guns and carronades actually carried, and not according to the erroneous denominations which had latterly grown into use. His late majesty William IV. made some alteration in this mode of rating ships, but not such as materially to interfere with the arrangement introduced by his predecessor. The royal navy, as at present constituted, comprises three principal classes: — 1. Rated ships and yachts, including razees, frigates, and corvettes. 2. Ships and bomb vessels, including vessels corvette-built or otherwise. 3. All smaller vessels, including brigs, ketches, brigantines, schooners, cutters, tenders, &c. Ships of the first class are commanded by captains; of the second class, by commanders; of the third class, by lieutenants and subordinate officers.

By the regulations of 1833, the following rates were established: — *First rate:* all three-decked ships. *Second rate:* one of her Majesty's yachts, and all two-decked ships whose war complements consist of 700 men and upwards. *Third rate:* the other royal yachts, and all yachts bearing the flag or pendant of an admiral or captain superintendent of a dock-yard; and all ships whose complements are under 700 and not less than 600. *Fourth rate:* ships whose complements are under 600 and not less than 400. *Fifth rate:* ships whose complements are under 400 and not less than 250. *Sixth rate;* ships whose complements are under 250.

Steam vessels are assigned a rate at the discretion of the lords of the admiralty. Ships or vessels fitted as troop ships, surveying ships, fire ships, store ships, or vessels used on any temporary service, are also given a rate not above the fourth. Ships of the 1st rate carry 100 guns and upwards; those of the 2d rate 80 and upwards; the 3d rate from 70 to 80; the 4th rate from 50 to 70; the 5th rate from 36 to 50; and the 6th rate from 24 to 36. (For the chief of these details we are indebted to an able and beautiful little work recently published, entitled an *Epitome of the Royal Naval Service of England*, by Mr. Miles.)

Government of the Navy. — The general direction and control of all affairs connected with the navy is intrusted, under her Majesty, to the lord high admiral, or to the commissioners for discharging the functions of that officer. The duties of the lord high admiral were formerly judicial as well as administrative; he having not merely to govern the navy, but to preside over a court for adjudging all nautical cases, and for taking cognizance of all offences committed on the high seas. But the judicial are now separated from the other duties of this high functionary, being devolved upon the judge of the Admiralty Court. *See* ADMIRALTY, COURT OF.

From the reign of Queen Anne down to the present time, with the exception of the short period during which William IV., when Duke of Clarence, held the office, the duties of the lord high admiral have been discharged by commissioners. These have consisted generally of a first lord, and of four or six junior lords. Civilians may be appointed to these offices; but at least two of the lords are always professional men. But, though assisted by junior lords practically, all the power and authority of the board is vested in the first lord. The powers exercised by the Board of Admiralty are very extensive and important. By their orders all ships are built, repaired, fitted for sea, or laid up in ordinary, broken up, or sold; put in commission, or out of commission; armed, stored, and provisioned; employed on the home or on foreign stations. All appointments or removals of commission and warrant officers are made by them, and all instructions issued for the guidance of their commanders; all promotions in the several ranks emanate from them; all honours bestowed for and without services, and all pensions, gratuities, and superannuations for wounds, infirmities, and long services, are granted on their recommendation. All returns from the fleet are sent to the Board of Admiralty, and every thing that relates to the discipline and good order of every ship. All orders for the payment of naval moneys are issued by the lords commissioners of the admiralty; and the annual estimate of the expenses of the navy, prepared by them, is laid before parliament for its sanction. All new inventions and experiments are submitted to them before being introduced into the service; all draughts of ships must have their approval; all repairs, alterations, and improvements in the dock-yards, and all new buildings, of every description, must be decided upon by them before they are undertaken. (*Sup. to Encyc. Britan.*, art. "Navy.")

Under the superintendence of the lords commissioners, the civil departments of the admiralty are directed by a surveyor of the navy, an accountant-general, a storekeeper-general, a comptroller of victualling, and a physician-general.

There are three gradations of admirals, viz. admirals, vice-admirals, and rear-admirals; and each of these dignities consists of three divisions, distinguished by the colour of their flags. Thus, there are admirals of the red, the white, and the blue squadrons, bearing their respective flags at the main-top-gallant-mast head; vice-admirals of the red, the white, and the blue squadrons, bearing their respective flags at the fore-top-gallant-mast head; and rear-admirals of the red, the white, and the blue squadrons, bearing their respective flags at the mizen-top-gallant-mast head. All admirals, whatever be their rank, take the common title of *flag officers*.

Admirals rank with generals in the army, vice-admirals with lieutenant-generals, and rear-admirals with major-generals. The command of each ship is entrusted to a captain, or to a commander, who has under him a certain number of lieutenants, according to the size of the ship, with a master, purser, midshipmen, gunners, &c. A captain of three years' standing ranks with a colonel in the army, and a captain of less than three years' standing with a lieutenant-colonel; a commander ranks with a major, and a lieutenant with a captain. The captain is responsible for the discipline and efficiency of the crew, and the good order of the ship. Notwithstanding he is furnished with minute instructions for his guidance in every particular, much must always necessarily depend on his conduct and character. He has power to order punishment to be inflicted; but it must be done in the presence of all the officers and ship's company. An account, stating all the circumstances, must also be entered in the ship's log, an abstract of which is forwarded each quarter to the admiralty. This regulation has tended to repress hasty and inconsiderate punishment; and has done much to improve the conduct of the officers, as well as to promote the proper discipline of the navy.

Composition of the Navy. — The navy is composed of two bodies of men — seamen and marines (*see* MARINES); and the officers under whose command it is placed are divided into three classes, viz. commissioned, warrant, and petty officers. Commissioned officers comprise flag officers (see *suprà*), commodores, captains, commanders, and lieutenants, appointed by commission from the lords commissioners of the admiralty, or by a commander-in-chief having authority in cases of vacancies by death or the decisions of courts martial abroad to make such appointments. Warrant officers are those who hold their appointment by warrant from the lords commissioners of the admiralty; to this class belong masters, secretaries, physicians, surgeons, &c. Petty officers are divided into two classes, *quarter-deck* and *working;* the former, comprising midshipmen, master's assistants, volunteers, &c., are entered by order of the lords commissioners, or by a commander-in-chief abroad; the latter, including captains of the maintop, foretop, &c. &c., are appointed by the captain or commander of the ship or vessel to which they belong.

Any person may enter the navy as a common seaman, on application to the commanding officer of any of her Majesty's ships in commission, provided he be approved by the examining surgeon, and have not previously been "discharged from the service with disgrace." Persons who have never been at sea are rated as landsmen, and seafaring men are rated as "ordinary" or "able" seamen, besides numerous gradations of petty officers, to which they are rated at the discretion of the commanding officer. Seamen are also obtained for the navy, at the breaking out of a war or any other emergency, by the practice of impressment. The antiquity and legality of this practice cannot be questioned; but very great and serious doubts have been and may be entertained as to its expediency. Foreigners are the only persons exempted at common law from impressment; but exemptions have been created by acts of parliament in favour of various classes, as landsmen, apprentices, seamen employed in the fisheries, watermen in the service of fire insurance companies, &c. *See* IMPRESSMENT.

Young gentlemen enter the service as volunteers of the first class; and every officer commissioning a ship is allowed to make one fresh entry. A volunteer must remain two complete years in that capacity, and attain the age of fourteen, before he can be rated a midshipman; when he has completed six years' service, and attained the age of nineteen, he may be examined in seamanship, and also in navigation, for the rank of lieutenant; and should he pass such examinations, he is eligible to hold a warrant as mate, if his conduct be satisfactory to his captain.

No person can receive a commission as lieutenant unless he have passed both the above examinations; but having done so, he is eligible for promotion to that rank. A lieutenant is not eligible for a commander's commis-

sion till he have served two years at sea in a ship of war as lieutenant; nor is a commander eligible for a captain's commission till he have served one complete year at sea in a ship of war as commander.

In 1830 a temporary restriction was placed on promotions by a minute of the Admiralty Board. This limited the promotion of officers to the rank of captain, and all below that rank to filling up one in three vacancies on the list, with the exception, viz., 1st, of death vacancies on foreign stations, which the commanders-in-chief have authority to fill up; 2d, the reservation to the admiralty of power to promote for special or brilliant services; 3d, of the occasion of a commander-in-chief striking his flag; and 4th, on the recommendation of the Board of Customs for services in the coast guard.

Captains and admirals are promoted by seniority, on what is termed a "flag promotion" taking place; but a captain must have served as under, in command of a rated ship, before he can obtain his flag; viz.

In war - - - -	4 years.
In war and peace combined -	5 —
In peace - - - -	6 —

All other classes of officers, as was remarked above, are promoted at the discretion of the Board of Admiralty. For the various important subjects connected with the pay, pension, discipline, &c. of the navy, see the *Navy List*. See, also, *Statistics of the British Empire;* and the valuable little work above referred to, *Epitome of the Royal Naval Service of England*, London, 1841. For other particulars relating to the navy, see NAVAL ARCHITECTURE, SHIP, and the other naval articles, which will be found under their respective heads in this work.

NA'ZARITE (Heb. nazar, *to separate*), signified, in the Jewish dispensation, one separated to the Lord by a vow. (Numbers, chap. 6.) The chief observances of the Nazarites were, to refrain from drinking wine, to suffer the hair to grow, and to avoid coming in contact with a corpse. This word must be distinguished from Nazarene, which signified a native of Nazareth, and was applied in contempt to the early Christians, inasmuch as they were followers of Jesus of Nazareth.

In some Eastern countries some Christian communities are still to be met with which have retained the appellation of Nazarenes. The sect of Nazarenes, which sprung up in Palestine in the second century, endeavoured to engraft the rites and observances of the Jews on the religion of Jesus Christ; in this respect they bore a considerable resemblance to the Ebionites, whose contemporaries they were, but with whom they must not be confounded. No traces of them existed in the 5th century.

NEAP, or NEEP TIDES, are the lowest tides, being those which are produced when the attractions of the sun and moon on the waters of the ocean are exerted in directions perpendicular to each other. When the two forces act in the same or exactly opposite directions, the *spring* or highest tides are produced. The neap tides take place about four or five days before the new and full moons. *See* TIDES.

NEAT. A term applied to cattle: *neat's foot oil* is the fat obtained by boiling calves' feet.

NE'BULÆ. (Lat. nebula, *a cloud*.) in Astronomy, the name given, on account of their general cloudy appearance, to a very numerous class of celestial objects, being, however, for by far the greater part, *telescopic*, and only visible in telescopes of considerable power.

It is to Sir William Herschel that astronomy is indebted for the first examination and analysis of these remarkable objects. A few of them have indeed been known since the discovery of the telescope, and one or two of them are visible to the naked eye; but his powerful telescopes first disclosed the fact of their existence in immense numbers, and in all quarters of the heavens, not indeed distributed uniformly, but, generally speaking, with a marked preference to a broad zone, crossing the milky-way nearly at right angles, and whose general direction is not very remote from that of the hour circle of 0^h and 12^h.

Nebulæ are divided by Sir W. Herschel into the following classes: — 1st, Clusters of stars, in which the stars are clearly distinguishable; 2d, Resolvable nebulæ, or such as excite a suspicion that they consist of stars, and which any increase of the optical power of the telescope might be expected to resolve into distinct stars; 3d, Nebulæ, properly so called, in which there is no appearance whatever of stars; 4th, Planetary nebulæ; 5th, Stellar nebulæ; and, 6th, Nebulous stars.

Clusters of Stars. — These are either globular or of an irregular figure, forming bright isolated patches, which attract attention, as if they were brought together by some general cause. The Pleiades is a cluster of this sort: the naked eye can distinctly perceive six or seven stars in it, and may catch occasional glimpses of a great many more; but the telescope shows fifty or sixty crowded together, in a very moderate space, and insulated from the rest of the heavens. A luminous spot, called *Præsepe*, or the Beehive, in the constellation Cancer, is resolved entirely into stars by an ordinary telescope. In the sword-handle of Perseus is another such spot, crowded with stars, but not so easily resolved. There are a great number of less distinct nebulous specks of the same kind, which in ordinary telescopes have much the appearance of comets without tails, and have frequently been mistaken for such; when, however, they are examined with instruments of great power, such as reflectors of 18 inches, 2 feet, or more in aperture, any such idea is completely destroyed. They are then, for the most part, perceived to consist entirely of stars, crowded together so as to occupy almost a definite outline, and to run up to a blaze of light in the centre, where their condensation is usually the greatest. Many of them are of an exactly round figure. Others, again, are of an irregular form, and less definite in their outline, so that it is not easy to say where they terminate. In some of them the stars are nearly all of a size, in others extremely different; and it is no uncommon thing to find a very red star, much brighter than the rest, occupying a conspicuous situation in the group. Sir W. Herschel regards these as globular clusters in a less advanced state of condensation; conceiving all such groups as approaching, by their mutual attraction, to the globular figure, and assembling themselves together from all the surrounding region.

Resolvable nebulæ are considered as objects of the same nature as the preceding; but as being either too remote, or consisting of stars too faint, to affect us by their individual light. They are universally round or oval; their irregularities of form being extinguished by the distance, and only the general figure of the condensed parts being discernible. In telescopes of insufficient optical power, all the great globular clusters exhibit themselves under this appearance.

Nebulæ, properly so called, present a great variety of appearances. One of the most remarkable is in the constellation Orion; and its appearance is very different from what might be supposed to arise from the aggregation of an immense collection of small stars. It is formed of little flocky masses, like wisps of cloud; and such wisps seem to adhere to many small stars at its outskirts, and especially to one considerable star, which it envelopes with a nebulous atmosphere of considerable extent and singular figure. This nebula was discovered by Huygens in 1656, who gave figures representing its appearance in his telescope. On comparing these with its present appearance, several astronomers have concluded that it has undergone a perceptible change; but the evidence of such change is by no means to be relied on. There is a nebula in the constellation of Andromeda visible to the naked eye, and often mistaken for a comet. Its appearance is described by Simon Marius as that of a candle shining through horn. Its form is a pretty long oval, increasing by insensible gradations of brightness, at first very gradually, but at last more rapidly, up to a central point, which, though very much brighter than the rest, is yet evidently not stellar, but only nebulous matter in a high state of condensation. It has in it a few small stars; but they are obviously casual; and the nebula itself offers not the slightest appearance to give ground for a suspicion of its consisting of stars. It is nearly half a degree long, and fifteen or twenty minutes broad. Like that last described, a very numerous class of nebulæ are of a round or oval figure, increasing more or less in density towards the central point. In this respect, however, they differ extremely; in some the condensation being slight and gradual, in others great and sudden. They also present great diversity of appearance, in respect of deviation from the spherical form. Some are only slightly elliptic, others much extended in length; and in some the extension is so great as to give the nebula the character of a long, narrow, spindle-shaped ray, tapering away at both ends to points. Some nebulæ are annular; but these are among the rarest objects in the heavens. The most conspicuous is situated half way between the stars β and γ Lyræ, and may be seen with a telescope of moderate power. It is small, and particularly well defined, so as to have, in fact, much more the appearance of a flat oval solid ring than of a nebula.

Planetary nebulæ have exactly the appearance of planets, — round or slightly oval disks, in some instances quite sharply terminated, in others a little hazy at the borders, and of a light exactly equable, or only a little mottled, which, in some of them, approaches in vividness to that of actual planets. Whatever the nature of these objects may be, they must be of enormous magnitude. One in Aquarius presents a diameter of 20″; another, in Andromeda, has a visible disk of 12″, perfectly defined and round. Granting them to be equally distant from us with the stars, their real dimensions must be such as would fill, on the lowest computation, the whole orbit of Uranus. Their intrinsic splendour must also be immeasurably inferior to that of the sun's; for a circular portion of the sun's disk, subtending an angle of 20″, would give a light equal to 100 *full moons*, whereas the nebulæ in question are hardly discernible with the naked eye.

Stellar nebulæ are those in which the condensation of the nebulous matter towards the centre is great and sudden; so sudden, indeed, as to present the appearance

of a dull and blotted star, or a star with a slight burr round it. The *nebulous stars* present the beautiful and striking phenomenon of a sharp and brilliant star, surrounded by a perfectly circular disk or atmosphere of faint light: in some cases dying away on all sides by insensible gradations, in others almost suddenly terminated. A very fine example of such a star is 55 Andromedæ, R. A. 1^h 43^m, N. P. D. 50° 7′.

"The nebulæ," says Sir J. Herschel, "furnish, in every point of view, an inexhaustible field of speculation and conjecture. That by far the largest of them consist of stars there can be little doubt; and in the interminable range of system upon system, and firmament upon firmament which we thus catch a glimpse of, the imagination is bewildered and lost. On the other hand, if it be true, as, to say the least, it seems extremely probable, that a phosphorescent or self-luminous matter also exists, disseminated through extensive regions of space, in the manner of a cloud or fog, now assuming capricious shapes, like actual clouds drifted by the wind, and now concentrating itself like a cometic atmosphere around particular stars, what, we naturally ask, is the nature and distinction of this nebulous matter? Is it absorbed by the stars in whose neighbourhood it is found, to furnish, by its condensation, their supply of light and heat? or is it progressively concentrating itself, by the effect of its own gravity, into masses, and so laying the foundations of new sidereal systems, or insulated stars? It is easier to propound such questions than to offer any probable reply to them." (See *Herschel's Treatise on Astronomy*, *Cabinet Cyclopædia*, from which the preceding description is abridged.)

NECE′SSITY, DOCTRINE OF. That scheme which represents all human actions and feelings as links in a chain of causation, determined by laws in every respect analogous to those by which the physical universe is governed. This doctrine has been attacked and defended with great zeal, in almost every period of speculative inquiry since the Reformation. The inductive method of research, applied by Bacon and his contemporaries to the phenomena of nature, led very soon to the adoption of a similar method in reference to the phenomena of mind. The discovery, or, rather, the distinct re-assertion of the law of association, by Hobbes, and the ready solution which it appeared to furnish of states of consciousness, which, without it, would have seemed capricious and unaccountable, encouraged many philosophers to attempt its application to every province of the human mind. It is only in connection with this fact that the prevalence of necessarian views in modern times can be adequately explained. Without venturing an opinion on the merits of the question at issue, between the advocates of free will and of necessity, we are sufficiently assured of the historical fact, that the distinction between man and nature, between the actions of a self-conscious agent and the workings of blind unintelligent powers, was considered by the great philosophers of antiquity as the groundwork of their systems of morality, and as involved in the very conception of moral science. It was natural that this distinction should be felt to be a barrier to the progress of the exclusively empirical psychology to which we have alluded. To the historians of man's nature the necessity of his actions appeared in the light of an hypothesis which lay at the very foundation of their inquiries, precisely as the natural philosopher is compelled to assume the regular recurrence of the same outward phenomena under the same circumstances. The psychologist considers the states of which he is conscious merely as they are related to each other in time; and, thus considered, it seems to him a mere identical proposition to assert that all that can be known of them is the order of their succession. If their succession were arbitrary or uncertain, nothing could be known of it, and the science which he professes could no longer have an existence. It is in this consideration, rather than in the dialectic subtleties by which the doctrine has been sometimes defended, that the real strength of the necessarian lies. So long as he can maintain the merely phenomenal character of human knowledge, he can reduce his opponents to the dilemma of either denying the possibility of mental science altogether, or of admitting the existence of those uniform laws which are its only object. In its relation to morality, the doctrine of necessity has been naturally considered to involve dangerous consequences. Attempts have been made by modern necessarians to rescue it from this imputation. Sir James Mackintosh, in particular, has devoted some portion of his Dissertation to the explanation of the principal ethical terms, on the necessarian hypothesis. (*General Remarks*, sec. vii. p. 393. of the reprint.) Notwithstanding the ingenuity of this effort, the student will probably find, on careful examination, that the great question at issue is left much in the same state as before.

NECK OF A CAPITAL. In Architecture, the space above the shaft of a column, between the annulet of the capital above and the astragal at the top of the shaft below.

NECRO′LOGY. (Gr. νέκρος, *dead*, and λόγος, *discourse*.) A collection of biographical notices of deceased persons, published shortly after their deaths, is commonly called a necrology. The list of deceased benefactors to a monastery, cathedral, &c., was also termed its necrology.

NE′CROMANCY. (Gr. νέκρος, and μάντεια, *prophecy*.) Divination by consulting the spirits of the dead. Necromancy is prohibited in Deuteronomy; and the passage in the first book of Samuel respecting the witch of Endor — whether it be understood of an actual evocation, or of a deception practised by a soothsayer — shows that necromancy, real or pretended, was among the usages of very distant times. In Homer, the portion of the *Odyssey* termed the Necyomanteia exhibits the superstition in a very peculiar form. Ulysses performs a sacrifice with peculiar solemnities, and pours the sacrificial blood into a ditch: the spectres of the dead rush wildly from the infernal regions to taste the blood; and, discovering that of Tiresias, of which he was in search, he compels it to answer his questions. The rest of the book, in which Ulysses appears actually to descend to the shades, and to see the punishments of celebrated criminals, is suspected by some commentators to have been an interpolation of later times. Similar customs in practising the art of necromancy seem to have been followed for a long period in Greece and Italy. Horace mentions the pouring of the blood of a sacrificed sheep into a ditch, in order to attract the manes from beneath. But in Thessaly, the most celebrated of classical regions for its proficiency in the art of magic, peculiar horrors seem to have attended the exercise of necromancy. Erichtho, Lucan's Thessalian witch, reanimates the corpse of a soldier slain in battle, and compels him to answer her questions respecting futurity. But the ψυχάγωγοι, or professed evokers of spirits, in Thessaly, seem to have performed their rites, whether as impostors or as fanatics, with the sacrifices of human beings and various other enormities. Modern necromancy, like most branches of divination in modern superstition, has been chiefly accomplished by the agency of devils, who either voluntarily or by compulsion act at the behest of the magician. *See* Magic, Witch.

NE′CROLITE. (Gr. νεκρος, and λιθος, *a stone*.) A mineral which is found in small nodules in the limestone of Baltimore, and which when struck exhales a fetid odour resembling that of putrid flesh.

NECRO′PHAGANS, *Necrophaga*. (Gr. νεκρος, and φαγω, *I eat*.) The name of a family of Clavicorn beetles, comprehending those which feed on dead and decomposing animal substances.

NECRO′SIS. (Gr. νεκρουν, *to destroy*.) This term is applied in surgery to the mortification of parts of bones.

Necrosis, or Spotting. In Botany, a disease of plants, chiefly found upon the leaves and soft parenchymatous parts of vegetables. It consists of small black spots, below which the substance of the plant decays.

NE′CTAR, in the Mythology of the Greeks and Romans, was the supposed drink of the immortal gods (ambrosia being their food), and was fabled to contribute largely to their immortality. If we believe the accounts of the poets, the qualities of this liquor must have been of a most delicious character. It imparted youth, bloom, and vigour to the body, and possessed the power of repairing all the defects and injuries of the mental constitution.

NECTA′RIUM. (Lat. nectar, *honey*.) Any part of a flower that secretes a honey-like substance. It is variously applied to modifications of the petals, stamens, and disk, and is now not much employed.

NEE′DLE, MAGNETICAL. A slender magnetized bar of steel, which, when suspended freely on a pivot or centre, arranges itself in the direction of the magnetic force of the earth. *See* Compass, Magnetism, Variation.

NEEDLE ORE. (From the acicular form of its crystals.) A native sulphuret of bismuth, copper, and lead: it occurs in the gold mine of Schlangenberg, in Siberia.

NEEDLE STONE. A species of acicular zeolite found in Iceland.

NE EXEAT REGNO. In Law, a writ to detain a person from going out of the kingdom without the king's licence, directed to the sheriff, or to the party himself. The use of the writ is to prevent a party from withdrawing his person and property from the jurisdiction of the courts in England; but this purpose was served at common law before the late Insolvent Act by arrest, and bail obtained. This writ lies, therefore, where there is a suit in equity for a demand for which the plaintiff could not arrest at law; and is always granted upon a bill just filed in equity.

NE′GATIVE, in Logic, denotes the quality of a proposition which denies the agreement between the subject and predicate.

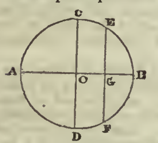
NE′GATIVE SIGN. In Algebra, the sign of subtraction, —. Any quantity to which this sign is prefixed is called a *negative* quantity.

The doctrine of negative quantities is attended with considerable difficulties, and has given rise to much discussion. When a negative quantity is preceded by a positive quantity greater than itself, nothing is simpler than the accurate notion of its signification. For instance, in the expression $a - b$, where a is greater than b, no difficulty can arise about the nature of the operation which is indicated. But in algebra quantities are constantly occurring of the form $a - b$, where b is greater than a; or of the form $-a$, where the negative quantity stands by itself; and it is often no easy matter, if indeed it be possible, to discover any exact principle by which such expressions are to be interpreted.

The definitions usually given by writers on algebra of isolated negative quantities are reducible to two:—1st, that negative quantities are less than nothing; and, 2d, that they are of the same nature as positive quantities, but taken in a contrary sense, or opposite direction. The first of these definitions, which, indeed, presents itself the most naturally, was adopted by Newton in the *Arithmetica Universalis*, and also by Euler, in his *Introductio in Analysin Infinitorum*. The second definition has been generally adopted by writers on the application of algebra to geometry and mechanics. But it has been shown by D'Alembert, and more particularly by Carnot, in his *Geométrie de Position*, that both definitions lead to inaccurate notions.

With regard to the first definition, D'Alembert reasons in this manner:—Let there be the proportion $1 : -1 :: -1 : 1$, which is true, because the product of the extremes is equal to the product of the means. Now, if -1 be less than nothing, much more will it be less than 1; therefore, the second term is less than the first; consequently the fourth must be less than the third: that is to say, 1 must be less than -1; therefore, -1 is both less than 1 and greater than 1, which is absurd. Carnot further remarks, that a multitude of paradoxes, or rather absurdities, arise from the notion that negative quantities are less than 0; for example, -3 must be less than 2, yet $(-3)^2$ would be greater than 2^2, because $(-3)^2$ is 9, and 2^2 is 4; that is to say, of two unequal quantities, 2 and -3, the square of the greater would be less than the square of the smaller, which is contrary to any clear and distinct notions that can be formed of the nature of quantity.

The principle that negative quantities are quantities taken in a different sense, or opposite direction to positive quantities, is shown by Carnot to lead to error by the following example:—Let A C B D be a circle, of which O is the centre, and A B a diameter; we have then A B = A O + O B. Through the centre O draw C D perpendicular to A B, and through any point in the circle E draw the chord E F parallel to C D, meeting A B in G.



Let A be the origin of the abscissa; and make A G $= x$, and G E $= y$; then, putting $a =$ the radius of the circle, we have the equation $y^2 = 2ax - x^2$. The solution of this quadratic gives $y = \pm\sqrt{2ax - x^2}$, which, according to the theory under consideration, shows that y has two values equal and directly opposite to each other; namely, G E represented by the positive root, and the other, G F, represented by the negative root; that is to say, we have G E $= +\sqrt{2ax - x^2}$, and G F $= -\sqrt{2ax - x^2}$, equations which ought to be true whatever be the value of A G or x. Let us, therefore, suppose A G = A O $= a$ · G E will then become O C, and G F will become O D; therefore, the two equations will become G E $= +a$, and G F $= -a$, and, consequently, G E + G F = 0; that is, A B = 0, which is absurd, although rigorously deduced from the theory. The theory, therefore, is false. It may be possible, Carnot remarks, to oppose metaphysical subtleties to this conclusion; but he thinks that no clear and satisfactory answer can be given to the argument.

Without entering into metaphysical subtleties, we may remark that there is an evident fallacy in the above conclusion, which arises from first assuming the signs + and − to be *symbols of interpretation*, and then considering them as *symbols of operation*; without regard to their directive signification. On making $x = a$, the two roots of the above quadratic are $+a$ and $-a$, and the signs are by the theory assumed to signify opposition or contrariety of direction. But in the equation $+x - a = o$ (from which G E + G F $= o$ is derived), the directive signification is entirely lost sight of; the signs are regarded as merely symbols of operation; and the equation being interpreted in the usual way simply affirms that the difference between the two roots, *in respect of absolute magnitude*, is nothing.

Having shown that the usually received notions respecting negative quantities are obscure and inaccurate, Carnot proceeds to establish the true principles of their theory. He concludes, 1st, That an isolated negative quantity is a mere creation of the mind, and that those which result from the operations of the calculus are nothing more than simple algebraic forms, incapable of representing any real and effective quantity whatever. 2d, That each of these forms, taken without reference to its sign, is nothing more than the difference of two other absolute quantities, of which the one that was the greater in the case on which the reasoning was founded, becomes the less in the case to which the results of the calculus producing that form is applicable.

According to this theory, the true meaning to be attached to the expression *negative quantity* is this:—An absolute quantity, which does not belong to the system on which the reasoning has been established, but to another system related to the former in such a manner that in order to render the formulæ for the first system applicable to it the sign which precedes it must be changed from + to −, or from − to +. For example, if y represent the difference between the two quantities a and z, it does not follow that, by substituting $-y$ for $+y$, the quantity represented by y becomes negative; but merely that, of the two quantities a and z, the one which was the greater in the case in which y has the sign + becomes the smaller when the sign of y is changed into −. The preceding remarks will suffice to give a notion of the nature of the difficulties which attend the rigorous interpretation of the negative sign in symbolical algebra. For full information on this abstruse subject, the reader is referred to the following works:—Carnot, *Geométrie de Position; Maseres on the Use of the Negative Sign; Warren on the Geometrical Representation of the Square Roots of Negative Quantities*, 1828; *Peacock's Algebra;* Id. *Report of the British Association for* 1834; *De Morgan's Trigonometry; Young's Mathematical Dissertations;* and the articles connected with the subject in the *Penny Cyclopædia*.

NE'GLIGENCE. (Lat. negligo, *to neglect.*) In the Fine Arts, a want of observance of admitted rules and principles in the several parts of a work; such as in costume, in the disposition of the light and shade, &c.

NE'GROES. The Ethiopian or fourth variety of the human race, according to the division of Blumenbach and his followers, widely spread over the surface of the earth; occupying almost the whole of Africa south of that great belt of desert which extends, in the latitude of the tropic of Cancer, from the Atlantic to the Red Sea. The distinctions of this race are marked aud peculiar; but they are not universal, or every where the same. Thus, the colour varies, although less so, perhaps, than that of any other of the great varieties of mankind; the Hottentots, and various southern tribes belonging to the Ethiopian race, are in this and other respects widely different from their brethren. The woolly hair, dark jet colour, and some external peculiarities of conformation, seem chiefly to belong to those numerous tribes which inhabit the west coast of Africa, between the equator and the tropic of Cancer. But, even within that region, some tribes are to be found whose physiognomy is very different from that which we are accustomed to regard as representing the Negro type. South of the equator many of the tribes are inferior in strength and stature, and very different in appearance: from this region many of the Brazilian negroes are imported. In New Guinea, off the south-eastern extremity of Asia, a native population is found with most of the characteristics of the African negro.

The Negro race appears to have been subjected to the tribute of furnishing slaves to its more powerful and intelligent neighbours from a very remote period of antiquity. Many ages before the first European slave ship had visited the coasts of Africa, the Arabs bore off slaves in their caravans, across the Sahara, to the northern coasts of the continent; and even in classical writers (Terence, for example), we find mention made of black or Ethiopian slaves. *See* SLAVE TRADE.

By the mixture of the Negro and white races the mulatto is produced; the Sambo is the offspring of a Negro and an American Indian. The numerous varieties of these mixed races, according to the proportion of Negro, European, or Indian blood in each, are classed and denominated accurately in the West Indies. It may, probably, be estimated that there are now on the continent and islands of America, including Negroes, Mulattos, but excluding those mixed races which have a larger proportion of European blood, about ten million individuals of African descent; viz.

In the United States - - -	3,500,000
British colonies - - - - -	900,000
Hayti - - - - -	700,000
Spanish, French, &c. West Indies -	1,200,000
Brazil - - - - - -	2,500,000
The free states of continental America, formerly Spanish colonies -	1,000,000
	9,800,000

Of whom five or six millions are now in a state of slavery;

the remainder, except in Hayti, forming an inferior and generally an oppressed class of free inhabitants. The ultimate destiny of this multitude of human beings is a matter of very anxious speculation. Hayti, peopled by the slaves of the French colony of St. Domingo, who threw off the yoke at the period of the French revolution, is the only region in which they have as yet established an independent community; and the progress of that community in civilization is not such as to encourage the sanguine hopes of the philanthropist.

It has long been a favourite theory of many philosophers that the negro races are naturally inferior in point of intellect, and do not possess the same capacity for improvement as the Europeans, or people of the Caucasian variety. This supposition has, however, been vehemently denied; and it has been contended over and over again that the peculiar circumstances under which they have been placed sufficiently account for the condition of the Africans — for their want of a literature and their low civilization. That great weight should be attached to the considerations now mentioned is true; but still we do not think that they are sufficient wholly to account for the existing state of things. Egypt was, at a very remote period, the principal seat of science and of art; and various nations of Africa were in contact with, and had a pretty extensive intercourse with, the Egyptians, and also with the Phœnicians, and afterwards the Romans. But they seem to have profited little or nothing by this association. And while the people of Greece, Asia Minor, and Magna Græcia raised themselves in a comparatively brief period to the highest pitch of civilization and refinement, the nations of Africa continue, without a solitary exception, down even to the present day, immersed in the grossest barbarism. Surely, however, during the space of 3000 or 4000 years, opportunities must have been afforded to some of them to make some advances. But if so, not one has had sagacity to profit by by them. Africa, in fact, does not seem to have produced a single great man. She has had no Hercules, no Minos, no Theseus, no Confucius, no Manco Capac. Among all the varieties of superstition that exist in it, we look in vain for hero-worship — for the divine honours paid in rude but improving nations in other parts of the world, by the public gratitude, to departed heroes, legislators, and authors of important discoveries in the arts.

With the exception of that of the ancient Egyptians and Ethiopians, whose descent is involved in the greatest uncertainty, almost all the civilization that exists in Africa seems to be of foreign origin. The introduction of Mohammedanism, though in a debased form, has gone far to banish cannibalism from many countries; and some of them have also adopted the letters and literature of Arabia. But the progress they have hitherto made is not such as to lead to any very sanguine anticipations as to their future advancement; and it would not, indeed, be very philosophical to suppose that those who have been wholly unable to produce any thing original should attain to much eminence in the practice of foreign arts and sciences.

It is unnecessary to enter into any examination of the *vexata questio* whether the varieties of the human race in Africa originally sprung from different sources, or whether they all belong to the same stock, but changed to the state in which we find them by the influence of circumstances in the lapse of ages. Whatever conclusion may be come to on this point cannot in anywise affect the question as to the comparative intelligence of the African people. The same circumstances that are supposed by those who contend for the original identity of the races to have so greatly affected their appearance and physical capacities, could hardly fail to have an equally powerful influence over their mental faculties. This in fact is substantially admitted by Dr. Pritchard, who has ably contended for their common origin, and the equality of their intellect with that of the other races. "The tribes," says he, "in whose prevalent conformation the negro type is discernible in an exaggerated degree, are uniformly in the lowest stage of human society; they are either ferocious savages, or stupid, sensual, and indolent. Such are the Papals, Bulloms, and other rude hordes on the coast of Western Guinea, and many tribes near the Slave coast, and in the Bight of Benin; countries where the slave trade has been carried on to the greatest extent, and has exercised its usually baneful influence. On the other hand, wherever we hear of a Negro state the inhabitants of which have attained any considerable degree of improvement in their social condition, we constantly find that their physical characters deviate considerably from the strongly marked or exaggerated type of the Negro. The Ashantee, the Sulema, the Dahomans, are exemplifications of this remark. The Negroes of Guber and Hausa, where a considerable degree of civilization has long existed, are, perhaps, the finest race of genuine Negroes in the whole continent, unless the Jolofs are to be excepted. The Jolofs have been a comparatively civilized people from the æra of their first discovery by the Portuguese." — (*Researches into the History of Man*, ii. 338. 3d ed.)

Here we have it distinctly laid down that the existence of the distinguishing features of the Negro race in a strongly marked degree is uniformly associated with the lowest state of barbarism; and that as they recede from this strongly marked type, we find a greater degree of civilization and improvement. The inevitable conclusion is, that every variety of the Negro type, which comprises the inhabitants of almost all central Africa, is indicative of mental inferiority; and that ferocity and stupidity are the characteristics of those tribes in which the peculiar Negro features are found most developed. We believe that this is a perfectly correct statement; and we do not know that any thing that can be said could show more conclusively the radical inferiority of the great bulk of the African people.

But we do not form our opinion as to their inferiority on their configuration and appearance, but on the fact that while numberless European and Asiatic nations have attained to a high state of civilization, they continue, with few exceptions, in nearly primeval barbarism. It is in vain to pretend that this is the result of the unfavourable circumstances under which they have been placed. An intelligent enterprising people contend against unfavourable circumstances, and make them become favourable; but the Africans, with the questionable exception of the ancient inhabitants of the valley of the Nile, have never discovered any considerable degree of enterprise or invention, or any wish to distinguish themselves either in arts or arms. From the remotest antiquity down to the present day they have been hewers of wood and drawers of water for others, and have made little or no progress; and the only legitimate inference from this lengthened induction seems to be, that they are incapable of making it; that civilization will not spring up spontaneously amongst them; and that if it ever grow up it must be introduced from abroad and fostered and matured under foreign auspices. (For full information on this subject, see the elaborate article on Africa in the *Geographical Dictionary*.)

NEHALLE'NIA. The name of an ancient Dutch and Flemish divinity who presided over commerce and navigation. Her origin and general character are unknown, and even her name suggests only forced and unsatisfactory associations; but the sixteen altars whereon her image and name were represented, which were found in the island Walcheren in 1647, leave no doubt of her former influence. (See *Grimm's Deutsche Mythologie*, and the authorities there cited.)

NEÏTH. One of the most ancient Egyptian deities, supposed to be identical with the Grecian Minerva or Rhea. Her name, according to Jablonski, indicates old or harmonious. She was regarded as an incarnation of nature, and as the patroness of all the arts. Her most celebrated temple was at Sais, where she was worshipped with peculiar veneration, and where stood the veiled image so famous in the mythology of Egypt, the rash inspection of which cost the adventurer either his life or his reason. (See Schiller's poem, "*Das verschleierte Bild zu Sais.*")

NEMATOI'DEANS, *Nematoidea*. (Gr. *νημα, a filament*, and *ειδος, form.*) The name of an order of *Cœlelmintha*, or cavitary intestinal worms, comprehending those which are diæcious, and have a round, filiform, elongated body.

NE'MATONEU'RA. (Gr. *νημα*, and *νευρον, nerve.*) A name proposed for that division of the *Radiata* of Cuvier, including animals in which nervous filaments are distinctly traceable, and the alimentary canal floats loosely in a distinct abdominal cavity.

NEM. CON. A contraction for *nemine contradicente*, signifying no one contradicting: *nem. diss.*, contracted for (Lat.) *nemine dissentiente*, signifies no one dissenting.

NE'MEAN GAMES. One of the four great national festivals of Greece, in which all the states participated. (*See* GAMES.) They were celebrated at Nemæa (whence their name), a village in the north-eastern part of Argolis. By some they are said to have been established by the Epigoni, children of the warriors who besieged Thebes, in memory of Ophaltes; but others relate that they were first instituted by Hercules, in honour of Jupiter, after his victory over the Nemean lion. They were held every third year, under the presidency of citizens chosen by lot from the states of Argos, Corinth, and Cleonæ. The games were the same as those of Olympia. The victorious combatants were crowned with parsley. See especially *Wachsmuth's Historical Antiquities of Greece*, Oxf. transl. vol. ii. 162.; and a memoir by Villoison, in the 38th volume of the *Mémoires de l'Ac. des Inscriptions*.

NE'MESIS. A Greek divinity, worshipped as the goddess of vengeance. According to Hesiod, she was the daughter of Night, and was represented as pursuing with inflexible hatred the proud and insolent. The reluctance of the Greeks to speak boastfully of their good fortune,

lest they should incur a reverse, is well known; and from various passages in the *Anthologia*, and other ancient writings, it is clear that this feeling originated in a desire to propitiate this divinity. The worship of this goddess was very extensive. Temples were erected to her honour, not only in Greece, but throughout the Roman empire. Nowhere, however, was her worship so pompously celebrated as at Rhamnus, a town of Attica, where she had a statue 10 cubits high of a single stone, and so exquisitely beautiful as to equal even the finest productions of Phidias. A fragment supposed to be the head of this statue was presented to the British Museum in 1820, where it may still be seen.

NEMO'CERA. (Gr. νημα, *a thread*, and κερας, *horn.*) The name of a family of Dipterous insects, including those which have long filiform antennæ.

NEMOGLOSSA'TA. (Gr. νημα, and γλωσσα, *a tongue.*) The name of a tribe of Hymenopterous insects, including those which have a long filiform tongue, as the bee tribe.

NEO'CORUS. (Gr. ναος, *temple*, and κορεω, *I take care of.*) In Grecian antiquities, the title of officers employed as guardians of temples and their treasures. (See *Mem. de l'Ac. des Inscr.* vol. xviii. 140.)

NE'OLOGISM, NE'OLOGY. (Gr. νεος, *new*, and λογος, *word.*) A new phrase or word introduced into a language, or any innovation on ordinary modes of expression. Most European tongues have their classical diction fixed by precedent and authority; and words introduced by bold or careless writers, since this standard was established, go by the name of neologisms until usage has added them at last to the received national vocabulary. *Neology*, in the last century, was the name given by orthodox divines in Germany to the novel system of interpretation which then began to be applied by many to the records of revealed religion. *See* RATIONALIST.

NEOME'NIA. (Gr. νεος, *new*, and μην, *a month.*) A festival observed by the Greeks at the beginning of every lunar month in honour of all the gods, but more especially of Apollo, thence called Νεομηνιος, as being the author of all light, and the grand luminary from which all time receives its distinctions and divisions. At these solemnities the Athenians offered up prayers and sacrifices, in the temple of Erechtheus, for the prosperity of their city during the month that had commenced. Games were also instituted during their celebration, and grand entertainments given by the richer to the poorer citizens.

NE'OPHYTE. (Gr. νεος, *young*; φυτος, *planted.*) In the primitive church newly converted Christians were so termed; and the same appellation is still given, in the Roman Catholic church, to converts made by missionaries among the heathen, to any person entering on the priestly office, and to those persons newly received into the communion of the church.

NE'OPLATONI'CIANS, or NEOPLATONISTS. In Ancient Literature, the mystical philosophers of the school of Ammonius Saccas and Plotinus are commonly so called, who mixed some tenets of ancient Platonism with others derived from a variety of sources, and particularly from the demonology of the East. They flourished in the 4th and 5th centuries of the Christian era. Some, however, have contended that this title is more properly applicable to the eclectic Platonists, or school of Antiochus and Philo. (*See* PLATONISTS, ECLECTICS.) For a singular view of the doctrines and tendency of the Neoplatonists, the reader may consult the *Quart. Rev.* July, 1840.

NEPE'NTHE. (Gr. νη, priv., and πενθος, *sorrow.*) A species of magic potion, mentioned by the Greeks and Romans, which was supposed to have the power of obliterating all pain and sorrow from the memory of those who partook of it. It is now used figuratively to express any efficient remedy in giving rest and consolation to an afflicted mind.

NEPHA'LIA. (Gr. νηφαλιος, *sober.*) Grecian festivals or sacrifices instituted in honour of various deities, as Aurora, Venus, &c. They were so called because no wine was offered during their celebration. It was chiefly at Athens that these festivals were observed.

NE'PHELINE. (Gr. νεφελη, *a cloud.*) A mineral from Somma, near Vesuvius, and Capo di Bova, near Rome; in nitric acid its transparent fragments become *cloudy*. It is a double silicate of alumina and soda. It is also known by the name of *sommite*.

NE'PHRITE. A hard tough mineral composed chiefly of silica, with lime, soda, and potash. It is difficult to break, cut, or polish; it is slightly translucent, and usually of a greenish colour. It is occasionally manufactured into sword and knife handles, and has even been cut into the form of a chain, which, from its extreme toughness, is not easily broken. Little plates of it were formerly suspended from the neck for the cure of *nephritic* complaints, whence its name. The Chinese are celebrated for articles composed of it. Its essential components are silica, alumina, and magnesia.

NEPHRI'TIS. (Gr. νεφρος, *a kidney.*) Inflammation of the kidney. This disease is attended by pain in the affected part, extending along the ureter, and increased on walking, or in the upright posture: nausea and vomiting are common attendants, and the appearance of the urine is generally far from healthy. Bleeding, warm baths, sudorifics, and aperients, with opiates and diluents, are the principal remedies resorted to.

NEPHRO'TOMY. (Gr. νεφρος, and τεμνω, *I cut.*) The operation of extracting a stone from the kidney.

NE'POTISM. A word invented to express a peculiar characteristic of many high ecclesiastics in Roman Catholic countries, and more particularly of popes: a propensity, namely, to aggrandize their family by exorbitant grants and favours conferred on members of it; literally, on nephews (nepotes). Many of the highest and wealthiest families of the Roman nobility owe their elevation entirely to this species of patronage.

NE'PTUNE. The Italian name of the deity called by the Greeks Poseidon (Ποσειδων). He was brother of Jupiter, and, in the partition of empire after the death of Saturn, the sea fell to his share, but in subservience to the former. His queen was Amphitrite, and his paramours nearly as numerous as those of his brother; but their progeny was not so celebrated, with the exception of the hero Pelops.

His most famous temples were at the Corinthian isthmus, Helicê, Træzen, and the promontories of Sunium and Tænarus; to which may be added the magnificent temple of Pæstum, in Italy, still in existence. Neptune was said to preside over horses and the manger. He is represented similar in appearance to Jupiter, but his symbols are a trident and the dolphin. *Neptunalia* were festivals celebrated by the Romans, during the months of July, in honour of Neptune. There were other festivals in honour of Neptune in his capacity of presiding over horses, called *consualia;* but the former were instituted to him in his character of god of the sea. During the solemnity it was customary to live in booths erected on the banks of the Tiber.

NEPTU'NIAN THEORY. The geological theory of Werner, which refers the formation of all rocks and strata to an aqueous origin.

NEREI'DEANS, *Nereideæ*. The name of the family of Dorsibranchiate Anellidans of which the genus *Nereis* is the type. The characters are, an even number of tentacula attached to the sides of the base of the head, and a little farther forwards two others which are biarticulate, between which are two simple ones. Their branchiæ consist of small laminæ, between which is spread a network of vessels; each foot is also furnished with two tubercles, two packets of bristles, one cirrus above and another beneath.

NE'REIDES. (Gr. Νηρειδες.) The daughters of Nereus and nymphs of the sea. They were originally conceived to be of a beautiful form, but later fictions degraded them to the idea of a mermaid. The nereids are said by most ancient writers to have been fifty in number, but Propertius makes them a hundred. Among the most famous of these goddesses were Amphitrite, Galatæa, Dido, Thetis, &c. Their worship was almost invariably connected with that of Neptune.

NE'REUS. (Gr. Νηρευς.) A marine Grecian deity, son of Ocean and Earth. He possessed the gift of prophecy, and was distinguished for his knowledge and love of truth and justice.

NERI'TA. (Lat. *Nerita*, the name of a shell-fish in Pliny.) This term was applied by Linnæus to a genus of his Vermes Testacea, characterized by having a shell with the columella in a straight line, which renders the aperture of a semicircular form: this aperture is always closed by an operculum. The genus is ranked by Cuvier amongst his Pectinibranchiate Gastropods, and is subdivided into the subgenera *Natica*, Lam., *Nerita*, *Voluta*, and *Neritina*, Lam. *Nerita* proper is a marine shell, while *Neritina* is an inhabitant of fresh waters. Examples of both genera are found fossil in the strata of the Paris basin.

NE'ROLI. The name given by perfumers to the essential oil of orange flowers. It is procured by distillation with water in the same way as the other volatile oils.

NE'RVINE. A medicine resorted to in nervous affections.

NE'RVOUS FEVER. A low fever in which nervous symptoms, or sensorial debility, are especially prevalent: the treatment consists in allaying nervous irritation and supporting the strength.

NERVOUS SYSTEM. In Physiology. The nerves are fibrous chords in direct or indirect connection with the brain, and extending their ramifications into every part of the body; their ultimate structure is filamentous, and they consist of a peculiar grey substance, their size depending upon the number of filaments enclosed in the common sheath. They are often so interwoven as to form a kind of network or *plexus;* and some of them have what are termed *ganglia*, or rounded masses of nervous matter, not fibrous, but apparently composed of globules disseminated through a vascular network.

There are two distinct systems of nerves; one of which is connected with the brain and with the spinal chord,

and are media of sensation and of voluntary motion: they are termed the nerves of *animal life*, or the *cerebro-spinal* nerves. The other system is only in communication with the brain and spinal chord, or with the cerebro-spinal nerves, by very small filaments, and they have numerous ganglions throughout their course; they preside over the nutritive functions, upon which the mind has no direct influence: these are the nerves of *organic life*, or *ganglionic* or great *sympathetic* nerves.

The cerebro-spinal nerves convey impressions from their extremities to the brain, and they also convey the influence of the will from the brain to the voluntary muscles; these passing and repassing, or receptive and emissive influences, are conveyed by distinct sets of nervous filaments, which, however, are generally enclosed in the same sheath, and therefore appear to form a single nerve: the terms *centripetal* and *centrifugal* filaments have been distinctively applied to them.

The history of the nervous system in all its details forms an extended and complicated, but a highly important part of anatomy and physiology, the investigations connected with which have led to many useful practical results, which, however, have thrown but little light upon the cause of the phenomena, or the ultimate nature of the nervous influence. The works of Sir Charles Bell, Dr. Marshall Hall, and Dr. Wilson Philip must be consulted in reference to the functions of the different classes of nerves; there is a good general account of the subject in Baly's translation of *Müller's Physiologie*.

NERVOUS SYSTEM. In Comp. Anat. In some of the lowest-organized animals the nervous system has been detected in the form of simple filaments; these are afterwards found connected with a nervous ring surrounding the œsophagus. As organization advances, nervous matter begins to be accumulated upon the ring, forming a brain; and upon different parts of the radiating filaments, forming ganglions.

When the principal gangliated filaments are not parallel, or not symmetrical in their course, they are associated with the type of organization which characterizes the molluscous or *heterogangliate* division of animals. When the gangliated filaments are two in number, symmetrical, and run parallel with each other along the ventral aspect of the body, they are associated with and bespeak the type of organization characteristic of the articulate or *homogangliate* division. When the brain ceases to present the form of a ring, and sends down the back a prolongation of its substance, called the spinal marrow, the rest of the organization is that which characterizes the vertebrate or *myelencephalous* subkingdom, or primary division of animals. In the vertebrate and articulate animals the superficial tract of the spinal or ventral chords is "sensitive," the deeper seated tract "motive."

NERVU'RES, in Entomology, are corneous tubes for expanding the wing and keeping it tense, and to afford protection to the air vessels: they are termed costal, post-costal, mediastinal, externo-median, interno-median, anal, axillary, &c., according to their relative positions. In Botany *nervures* are the veins of leaves.

NESS. The termination of several names of places in Great Britain where there is a headland or promontory, as Inverness, Sheerness. The word is probably derived from the Fr. nez, or the Germ. nase, *nose*.

NESTO'RIANS. The followers of Nestorius, patriarch of Constantinople, in the first half of the fifth century. This prelate agitated the Christian world, after the Arian controversy had been quietly settled, by the introduction of certain subtle disputations concerning the incarnation of our Lord, from whence debates and contentions arose which harassed the church for the space of more than two centuries. He affected to distinguish with peculiar precision between the divine and human natures united in Christ; and, in guarding over carefully against the propensity which he discovered in the Christians of his own day to confuse the two, and look upon them as absorbed into one compound substance, he forbade men to entertain any combined notion at all, and kept constantly before their eyes both the god and the man. He insisted, for instance, that the Virgin should not be entitled *Mother of God*, but *Mother of Christ*, or of *Man*, the human nature being essentially distinct from and only inhabited by the divine, as a temple by its divinity. The opinions of the Nestorians were, indeed, little more than subtle logical refinements upon mysteries which will not bear the application of such tests; and it was the habit of mind which they engendered that chiefly rendered them pernicious, and the fierce passions with which they were combined that gave them their celebrity and widely extended influence. Nestorius himself was condemned by the third general council held at Ephesus, in the year 431: his principal adversary being the president of the assembly, Cyril, the learned patriarch of Alexandria. The heretical prelate was deposed, and banished by the emperor to an oasis in Upper Egypt, where he died. His opinions, however, spread throughout Asia, and appear to have been carried along, with the advancing stream of Christianity, to the furthest parts of India and China. In more central regions, they were soon afterwards counteracted by the spread of the opposite heresy of Eutyches. For notices of the opinions which sprang out of these rival dogmatists, see INCARNATION, EUTYCHIANS, MONOPHYSITES, MONOTHELITES. Besides the well-known authorities, the reader may consult Doucin, *Hist. du Nestorianisme*, 1698; *Assemann's Biblioth. Orientalis*; and *Grant's Residence among the Nestorian Christians*, 8vo, 1841.

NESTS, ESCULENT. A species of nests built by swallows peculiar to the Indian islands, and very much esteemed in China and other parts of the world. These nests resemble in form those of other swallows; they are formed of a viscid substance, and in external appearance as well as consistence are not unlike fibrate ill-concocted isinglass. Esculent nests are principally found in Java, in caverns usually situated on the sea-coast. Nothing satisfactory is known as to the substance of which these nests are composed. (See the *Commercial Dict.*, art. "Birds' Nests.")

NET, or NEAT. In Commerce, something pure and unadulterated with any foreign mixture. Thus, wines are said to be *net* when not falsified; and coffee, rice, &c., to be so, when the filth and ordures are separated from them. The word *net* is also used for what remains after the tare has been taken out of any merchandize; *i. e.* when it is weighed clear of all package. (*See* TARE.) *Net Produce* (Ital. netto proceduto) is used in mercantile language to express what any commodity has yielded, after all tare and charges have been deducted.

NET (Germ. netz), is a textile fabric of knotted meshes for catching fish, and other purposes. Each mesh should be so secured as to be incapable of enlargement or diminution. The French government offered in 1802 a prize of 10,000 francs to the person who should invent a machine for making nets upon automatic principles, and adjudged it to M. Buron, who presented his mechanical invention to the *Conservatoire des Arts et Métiers*. It does not appear, however, that this machine has accomplished the object in view; for no establishment was ever mounted to carry it into execution. Nets are usually made by the fishermen and their families during periods of leisure. The formation of a mesh is too simple a matter to require description in this dictionary.

NE'THINIMS. Among the Jews, the servants of the priests and Levites, employed in the lowest and meanest offices about the temples. They were, as the Scripture expresses it, "the hewers of wood and drawers of water for the house of God." To this office the descendants of the Gibeonites were originally condemned by Joshua; but at a later period the same duties were assigned to the Canaanites who had surrendered themselves and were spared.

NE'TTINGS. Nets of small rope placed in a ship for various purposes, as stowage, or defence against accidents; also against boarding.

NE'TTLERASH. An eruption upon the skin much resembling the sting of a nettle. It usually lasts for a few hours, and then disappears or changes its place; it is relieved by bathing the affected part with a mixture of one part of vinegar and eight or ten of water, and by mild aperient medicines.

NEURA'LGIA. (Gr. νευρον, *a nerve*, and αλγος, *pain*.) An acute painful affection in the course of the nerves, generally subject to intermission. One of the most distressing forms of this disease is the *tic douleureux*.

NEURO'LOGY. (Gr. νευρον, and λογος, *a description*.) The doctrine of the nerves. *See* NERVOUS SYSTEM.

NEURO'MA. (Gr. νευρον.) A tumour formed in or upon a nervous trunk.

NEURO'PTERANS, *Neuroptera*. (Gr. νευρον, *a nerve*, πτερον, *a wing*.) The order of Tetrapterous Mandibulate insects, including those in which the nervures of the wings are so disposed as to form a more or less regular network. They are distinguished from the Coleopterous, Orthopterous, and Hemipterous orders of four-winged insects, by the first or anterior pair of wings being membranous, diaphanous, and resembling the second pair in texture and properties. The abdomen is unprovided with a sting. The antennæ are usually setaceous. Some neuropterans merely pass through a semi-metamorphosis, the rest a complete one; the larvæ have always six hooked feet. Many of these insects are carnivorous in their first state and their last. The dragon-fly may be regarded as the type of this order.

NEURO'TOMY. (Gr. νευρον, and τεμνω, *I cut*.) The cutting of a nerve.

NEU'TER (Lat. *neither*), in Grammar, signifies that gender which nouns possess that are neither masculine nor feminine. *Neuter* or *intransitive* verbs are those which represent the properties of a state or process, as *I rest*, *I fall*, *I grow*, &c. *See* GRAMMAR.

Neuter was the name given to the "labourers" of the hive-bee before it was discovered that they were essentially females, though infertile.

NEUTRA'LITY. In International Law, the condition of a state which does not take part in a war between other states. A neutral nation has the right of

furnishing to either of the contending parties all supplies which do not fall within the description of *contraband of war* (*see* CONTRABAND OF WAR), and to conclude treaties with either unconnected with the subject of the war. It appears to have been the old principle, with regard to the maritime trade of a neutral nation, that the property of an owner belonging to the hostile country might be seized by a belligerent on board a neutral power's vessel; but the general rule now asserted is that the flag covers the cargo: by which means right of search, except for specific purposes, is rendered unnecessary. But this rule is in effect set aside, according to the will or necessities of the most powerful belligerent, as it was during the last wars between England and the Continental powers.

NEUTRA'LIZATION. (Lat. neuter, *neither.*) In Chemistry, the combination of an acid and alkali in such proportions that the peculiar properties of each are rendered inert.

NEU'TRAL SALTS. Combinations of acids and bases which are neither acid nor alkaline, but in which the acid is exactly *neutralized* by the base.

NEUVAI'NES. (Fr. neuf, *nine.*) In the Roman Catholic Church, prayers offered up for nine successive days, in order to obtain the favour of Heaven. (See the *Dict. de la Conversation.*)

NEW CONNEXION METHODISTS, or KILHAMITES; so called from Mr. Alexander Kilham, who was the immediate means of their separation from the Wesleyans, and withdrew from this body on the ground of the almost irresponsible power exercised by the Conference. Having petitioned this convocation that the people might have a voice in the formation of the laws by which they were to be regulated, the choice of their own pastors and other officers, and the disposal of their own property, and those demands having been refused, the petitioners receded, and formed (1793) a distinct party, on a more liberal basis. The members of this body do not exceed 13,000. (*Life of Kilham*, by Thom and Grundel; *General Rules of the New Connexion Methodists.*)

NE'WEL. (Fr. noyau.) In Architecture, the space, either solid or open, round which the steps of a staircase are turned about.

NEW RED SANDSTONE. The sandstone immediately above the coal measures. *See* GEOLOGY.

NEWS. (Germ. neues, Lat. novus, Gr. νεος.) Literally, fresh information. This word has been fancifully derived from the initial letters of the four cardinal points of the compass, *n*orth, *e*ast, *w*est, and *s*outh.

NEW'SPAPERS. Publications in numbers, consisting commonly of single sheets, and published at short and stated intervals, conveying intelligence of passing events. In Rome, under the government of the emperors, periodical notices of passing events (diurna, acta diurna) were compiled and distributed for general reading; but our accounts of these ancient newspapers, derived from classical sources, are somewhat obscure and uncertain. In modern Europe, the earliest occasional sheets of daily intelligence seem to have appeared at Venice, during the war of 1563 against the Turks (*see* GAZETTE); and the earliest regular paper to have been a monthly one, published in the same city by the state: but these were distributed in manuscript, and, owing to the jealousy of the government, continued to be so down to very late times. Extraordinary gazettes are said to have been published in England by authority, during the time when the arrival of the Spanish Armada was apprehended; but the specimens preserved in the British Museum, and so long regarded as authentic, seem now to be demonstrated forgeries. The *Mercuries, Intelligencers*, &c. of the civil wars, seem to have been the first English papers which appeared regularly. The *Gazette de France* appeared regularly from 1631 to 1792, forming a collection of 163 volumes; it was continued, also, but with some interruptions, through the period of the Revolution; and the name still exists, the journal so called being at present one of the organs of the Carlist party. From their first imperfect beginning newspapers have gradually increased in number, matter, and consequence, until they form, in many European countries, one of the most important features in the social economy of the people; exercising a marked influence on domestic manners, literature, and usages, but more especially powerful as a great political instrument. In France newspapers are generally undertaken in shares. The editors and principal writers are more responsible and more generally known than in England: this is either a cause or an effect of the general prejudice in that country against anonymous writing, which is by no means so common as among ourselves; but, perhaps, one of its consequences is, that newspapers are more notoriously under the control of particular sections of the political world, or of powerful individuals. Political newspapers have their subsidiary articles on subjects of theatrical or literary criticism added in the shape technically termed *feuilleton*, a subdivision of the page. This custom was introduced about 1800 in the most influential paper of that period, and has since been generally followed. The periodical press of France was under strict control during the Empire: the censorship was continued until 1819, and re-established in 1820, but again abolished in 1821. At that period a law was passed compelling the proprietors to give security for the good conduct of their journals, under a penalty of 10,000 francs in Paris, and various lesser sums in the departments. The censorship was, however, again instituted, and again abolished in 1827. By the famous ordinances of 1830 the liberty of the periodical press was suspended. Since the revolution of that year there has been no attempt at re-establishing the censorship, although, in 1835, laws of a very severe character were passed, to subject the proprietors of journals to easier conviction, and heavier punishment, in case of trangressing the existing laws of libel against government or individuals, and extending and multiplying the provisions of that law. There were published in Paris, in 1839, 309 journals of all sorts, political, literary, scientific, &c.

In Great Britain newspapers are subjected to several statutory enactments. By 38 G. 3. c. 78. no person can print or publish any newspaper until an affidavit has been delivered at the stamp office, stating the name and places of abode of the printer, publisher, and proprietor; specifying the amount of shares in the undertaking, the title of the paper, and description of the building in which it is intended that the paper shall be printed. A copy of every newspaper is to be delivered, within six days after publication, to the commissioners of stamps, under a penalty of 100*l.* Persons publishing newspapers without the name and place of abode of the printer affixed may be apprehended and carried before a magistrate; and peace officers, by virtue of a warrant from a justice of the peace, may enter any place to make search, &c. By 60 G. 3. c. 9. every periodical pamphlet or paper, published at intervals not exceeding 26 days, containing public news or intelligence, or any remarks thereon, or on any matter in church or state, not containing more than two sheets, or published at a less price than sixpence, shall be deemed newspapers, and subject to the same regulations and stamp duties. By 1 W. 4. c. 73. securities may be demanded, to the amount of 400*l.* or 300*l.*, from both principal and sureties, when it is intended to publish a newspaper or pamphlet of the description mentioned in 60 G. 3. c. 9. These securities are intended to secure payment of damages or costs which may be incurred in an action for libel against the conductor of the paper. The laws respecting the stamp duties on newspapers have been recently placed on a new footing (in 1836). The effect of these restrictive provisions, and of the heavy rate of duty imposed on newspapers in England, is to create, especially in London, great monopolies, and to diminish the number of periodical papers, at the same time that their importance, and, according to the defenders of the system, their respectability and usefulness, is increased. There have rarely been more than five or six daily morning papers in London, and about as many evening. Of one of the former (*The Times*) the net profits have been estimated in some years at 24,000*l.* A morning paper in considerable circulation generally employs an editor, a sub-editor, from ten to fourteen regular reporters (*see* NEWSPAPER REPORTING), from thirty to thirty-five compositors, &c.; while the power and rapidity of the machinery which produces these huge sheets has been greatly increased of late years by the application of the steam engine. The evening newspapers, the apparatus of which is in other respects less costly, go to an enormous expense in procuring rapid intelligence from distant quarters. The irregular or occasional reporters are a numerous class: they multiply copies of the pieces of intelligence which they collect by means of polygraphs, and send them round to different newspapers to take the chance of their insertion.

The following calculation was formed, in 1827, of the number of periodical papers appearing in various countries, since which period it is probable that there has been a considerable increase:—Great Britain and Ireland, 483; France, 490; Russia, 288; Netherlands (Holland and Belgium), 160; German Confederation, excluding Austria and Prussia, 305; Sweden, 82; Denmark, 80; States of the Church, 6 only. It is obvious that without an approximation to the amount of copies of each newspaper, this calculation furnishes no grounds whatever for speculating on the proportion between the demand and supply of newspapers and the population in these respective countries; and wherever (as in England) newspapers are subjected to a heavy duty, each individual paper must necessarily sell a greater number of copies than elsewhere, in order to afford a profit; but the circulation of some French newspapers is said to exceed that of any among ourselves. The United States, at the same time, had 800 newspapers, and have at present upwards of 1000: about fifty of these appear daily. (See, among other antiquarian authorities as to early newspapers, *D'Israeli's Curiosities of Literature*, vol. i.; *Chalmers's Life of Ruddiman;* and the *Conv. Lexicon*, art. "Zeitung." See also the *Commercial Dictionary.*)

NEWSPAPER REPORTING. The name given to that system whereby the parliamentary debates and speeches delivered at public meetings, &c. are promulgated throughout the country. As it is contrary to the rules of both Houses that any stranger should be present, the publication of the debates is held to be a breach of privilege; but this regulation has always been defeated, either, as in former times, by the means adopted by Dr. Johnson and others of publishing the speeches of the different members under fictitious names, or, as at present, by the Houses themselves tacitly giving their sanction to the practice. The foundation of the present system of parliamentary reporting may be fairly ascribed to the late Mr. William Woodfall, whose retentive memory enabled him, after having listened to the debates, daily to communicate to the public, in what he called *A hasty Sketch of the Proceedings in Parliament last Night*, a full and most accurate account of the different speeches. Secret deliberations, however, have been so long renounced, that the right of the public to be present through their agents, the reporters, is as clearly established now as if no theoretical privacy had ever existed; but if any member were repeatedly to insist upon the exclusion of 'strangers,' as all are called who neither are members nor officers of the house, there can be no doubt that this abuse of the privilege must lead to such a modification of the standing order as would deprive individual members of any control over a matter so interesting to the nation. The process of parliamentary reporting, and the qualifications of those by whom the task is performed, cannot be adequately described within the narrow limits of this article; but it is hoped that the reader may be enabled to form some idea of both from the following brief outline. Every publication not copying from, or abridging any other, but giving original reports, keeps one of a series of reporters constantly in the gallery of the Lords, and another in the Commons. These, like sentinels, are at stated periods relieved by their colleagues, when they take advantage of the interval to transcribe their notes, in order to be ready again to resume the duty of note-taking, and afterwards that of transcription for the press. A succession of reporters for each establishment is thus maintained, and the process of writing from their notes never interrupted till an account of the whole debates of the evening has been committed to the hands of the printer. There are only seven publications for which a reporter is constantly in attendance; and these include the London morning newspapers, from which all others that give debates are under the necessity of copying or abridging them. The number of reporters maintained by each varies from ten or eleven to seventeen or eighteen. They are for the most part gentlemen of liberal education — many having graduated at the Universities of Oxford, Cambridge, Edinburgh, Glasgow, or Dublin; and they must all possess a competent knowledge of the multifarious subjects which come under the consideration of parliament. The expedition and ability with which their duties are performed must be admitted by every one who attends a debate and afterwards reads a newspaper, while the correctness and rapidity with which their manuscript is put in type and printed has long been a subject of surprise and admiration. (See the ***Parliamentary Companion***, a valuable brochure.)

NEW STYLE. In Chronology. *See* STYLE.

NEW TESTAMENT. The name given to that portion of the Bible which comprises the writings of the apostles and their immediate disciples. It consists of five historical books, viz. the respective Gospels of Matthew, Mark, Luke, and John, and the Acts of the Apostles (attributed to Luke); of twenty-one apostolical epistles, of which the early fathers have unanimously ascribed fourteen to St. Paul, three to St. John, two to St. Peter, one to St. James, and one to St. Jude; and of the book known by the name of the Apocalypse or the Revelation of St. John. *See* BIBLE, EPISTLE, EVANGELISTS.

NEWTO'NIAN PHILOSOPHY. This term is used in various senses. Sometimes it is used to denote the doctrine of the universe as delivered by Sir Isaac Newton in the *Principia;* sometimes the corpuscular, or modern, or experimental philosophy, as opposed to the the theories of Descartes and others; but most frequently, perhaps, the mathematical theory of universal gravitation. *See* GRAVITATION, PHYSICS.

NEW YEAR'S DAY. The celebration of the commencement of the new year dates from high antiquity. The Jews regarded it as the anniversary of Adam's birthday, and celebrated it with splendid entertainments, — a practice which they have continued down to the present time. The Romans also made this a holiday, and dedicated it to Janus with rich and numerous sacrifices; the newly elected magistracy entered upon their duties on this day; all undertakings then commenced were considered sure to terminate favourably; the people made each other presents of gilt dates, figs, and plums; and even the emperors received from their subjects new year's gifts, which at a later period it became compulsory to bestow. From the Romans the custom of making presents on New Year's Day was borrowed by the Christians, by whom it was long retained; but even in those countries where it lingered longest, in France and Scotland for instance, it is falling rapidly into desuetude, and congratulatory wishes are now almost universally substituted for the more substantial presents that were formerly conferred on this day as marks of affection and esteem.

NEX'I. (Lat. necto, *I bind.*) In Roman Antiquities, persons freeborn, who, for debt, were delivered bound to a creditor, and obliged to serve him until they could discharge it.

NIBELUNGEN, LAY OF THE. The name given to the most ancient existing monument of German epic poetry. The origin of this poem is veiled in great obscurity; it is supposed to have existed, in substance at least, two centuries before the reign of Charlemagne, and, like the early compositions of poets in all ages, to have consisted originally of detached ballads and poems, which were afterwards gradually collected, and at length moulded into the complete form in which they at present exist. The last of the modifications which it underwent took place towards the end of the 12th century, and is attributed to the Minnesaenger Henrich von Ofterdingen. The story turns upon the adventures of Chrimhold of Burgundy, who is first won by the valiant Siegfried, and after he is treacherously murdered gives her hand to Attila, king of the Huns, chiefly in the hope that through his power and influence she may be revenged on the murderers of her former lord. The assassins, accordingly, and all their kin, are induced to visit Attila, when, by the instigation of the queen, a deadly feud arises, in the course of which almost the whole army on both sides is cruelly slaughtered. By the powerful but reluctant aid of Diederich of Bern, however, the murderer of Siegfried is at last vanquished, and brought bound to the feet of the queen, who relentlessly raises the sword of the departed hero, and with her own hand strikes off the head of his enemy. The famous Hildebrand, whose exploits are depicted on the *Helden-Buch*, instantly avenged the atrocious and inhospitable act by stabbing the queen, who falls exulting on the body of her hated victim. The work is divided into thirty-eight books. The *Nibelungen Lied* formed for many centuries the chief traditionary record of the romantic deeds and sentiments of the German nation, but at the era of the Reformation it sank wholly into oblivion; from which, however, it has within the last thirty years been rescued, and permanently placed by the labours and commentaries of Hagen, Zeune, Simrock, and Schlegel, among the most conspicuous monuments of human genius. All the questions relating to its origin, nature, and characteristics are discussed with great interest by the German literati, to many of whom indeed it forms a distinct branch of study; and we cannot refrain from inserting in our pages Schlegel's notice of this poem which, whatever interest it has excited in Germany, is still comparatively unknown in England.

Among the heroic poems of those nations which, in contradistinction to those of the Greeks and Romans, whose skilful unfolding of incidents and dramatic vividness of representation were peculiar and unrivalled, have remained satisfied with a more simple mode of poetry, the *Nibelungen Lied* claims a very high place, — perhaps among all the heroic chivalrous poems of modern Europe, it is entitled to the first. It is peculiarly distinguished by its unity of plan; or rather it is a series of pictures, each naturally following the other, and all delineated with great boldness and simplicity and a total disregard of all superfluities. The German language appears in this work in a state of perfection to which in the subsequent periods of its early history it had no pretensions. In addition to all its natural liveliness and strength, it seems at that time to have possessed great flexibility, which soon afterwards gave place to a style of affectation, roughness, and indistinctness. The heroic legends of all nations have a great deal in common, so far as their essence and purpose are concerned; their variety is only produced by their being imbued with the peculiar feelings and composed in the peculiar measures of different nations. In the *Nibelungen Lied*, in the same manner as in the legends of Troy and of Iceland, the interest turns on the fate of a youthful hero, who is represented as invested with all the attributes of beauty, magnanimity, and triumph, but dearly purchasing all these perishable glories by the certainty of an early and predicted death. In his person, as is usual, we have a living type both of the splendour and the decline of the heroic world. The poem closes with the description of a great catastrophe borrowed from a half-historical incident in the early traditions of the north. In this respect also, as in many others, we cannot fail to perceive a resemblance to the *Iliad*. If the last catastrophe of the German poem be one more tragical, bloody, and titanic than any thing in Homer, the death of the German hero, on the other hand, has in it more solemnity and stillness, and is withal

depicted with more exquisite touches of tenderness, than any similar scene in any heroic poem with which we are acquainted. The *Nibelungen Lied* is, moreover, a poem abounding in variety; in it both sides of human life, the joyful as well as the sorrowful, are depicted in all their reality. The promise of the opening stanza is fulfilled:—

Von Freuden und Festes Zeiten, von Weinen und von Klagen,
Von kühner Helden Streiten, mögt Ihr nun Wunder hören sagen.

(*Schlegel's History of Literature*, Edin. 1818, vol. i. p. 270. 272.) See, for further information, the *Conversations-Lexicon*, and the works there referred to.

NICARA'GUA WOOD. The wood of the *Cæsalpina echinata*, a tree growing in Nicaragua; it is a species of Brazil wood. It is used with solution of tin as a mordant to dye a bright but fugitive red. Nicaragua woods differ greatly in their quality as well as price; one sort being so deficient in colouring matter that six pounds of it will only dye as much wool or cloth as one pound of Brazil wood, while another variety of it will produce nearly half the effect of an equal quantity of Brazil wood, and will sell proportionally dear. (*Bancroft on Colours*, vol. ii. p. 332.)

NICE, COUNCIL OF. The first, and, according to most writers, the most important, œcumenical council held in the Christian church. It was convened, A. D. 325, at Nicæa, by the emperor Constantine, in order to settle differences that had arisen in the Christian church in respect to the doctrines of Arius. This council was attended by upwards of 250 bishops, of whom a great majority came from the East, besides presbyters, deacons, and others from all parts of the Christian world. The chief question, as was remarked above, was the Arian heresy; and the council issued in the excommunication of Arius. (*See* ARIANS.) The decision of this council had not the effect of restoring tranquillity to the Eastern church, for the Arian controversy was still warmly carried on; but it has supplied that mode of stating the doctrine of the Divinity (as far as relates to the Father and Son) in which it has ever since been received by the orthodox. *See* NICENE CREED, COUNCIL.

NICE'NE CREED. The confession of faith in which the consubstantiality of the Father and Son is asserted against the Arians. (*See* art. ARIANS.) This creed was commenced by the council of Nice, A. D. 325, and completed by the second general council of Constantinople, A. D. 381. But the words "and the Son," after those "who proceedeth from the Father," were added by the Latin church (certainly before A. D. 411), expressing a point of doctrine in which it differs from the Greek. The Nicene creed was generally used by the Eastern churches in the administration of baptism; but was not inserted in their daily service till the fifth century. In the service of the church of Rome it was inscribed A. D. 1014.

NICHE. (Fr. niche.) In Architecture, a square or cylindrical recess in a wall, usually made for the reception of a statue.

NICKEL. A white metal, ductile, malleable, attracted by the magnet, and which, like iron, may be rendered magnetic. Its specific gravity when hammered is about 9. It is rather more fusible than pure iron; is not altered by exposure to air and moisture at common temperatures, but is slowly oxidized at a red heat. It is found in all meteoric iron; but its principal ore is a copper-coloured mineral found in Westphalia, and called *kupfernickel*, nickel being a term of detraction used by the German miners, who expected from the colour of the ore to find that it contained copper. The salifiable oxide of nickel consists of 30 nickel + 8 oxygen. Its salts are mostly of a grass-green colour, and the ammoniacal solution of its oxide is deep blue, like that of copper. Ferrocyanate of potassa precipitates it of a white or very pale green colour.

Since the manufacture of German silver, or *argentane*, became an object of commercial importance, the extraction of nickel has been undertaken upon a considerable scale. The cobalt ores are its most fruitful sources, and they are now treated by the method of Wöhler to effect the separation of the two metals. The arsenic is expelled by roasting the powdered *speise* first by itself, next with the addition of charcoal powder, till the garlic smell be no longer perceived. The residuum is to be mixed with three parts of sulphur and one of potash, melted in a crucible with a gentle heat, and the product being edulcorated with water leaves a powder of metallic lustre, which is a sulphuret of nickel free from arsenic; while the arsenic associated with the sulphur, and combined with the resulting sulphuret of potassium, remains dissolved. Should any arsenic still be found in the sulphuret, as may happen if the first roasting heat was too great, the above process must be repeated. The sulphuret must be finally washed, dissolved in concentrated sulphuric acid, with the addition of a little nitric; the metal must be precipitated by a carbonated alkali, and the carbonate reduced with charcoal.

In operating upon kupfernickel, or speise, in which nickel predominates, after the arsenic, iron, and copper have been separated, ammonia is to be digested upon the mixed oxides of cobalt and nickel, which will dissolve them into a blue liquor. This being diluted with distilled water deprived of its air by boiling, is to be decomposed by caustic potash till the blue colour disappears, when the whole is to be put into a bottle tightly stoppered, and set aside to settle. The green precipitate of oxide of nickel, which slowly forms, being freed by decantation from the supernatant red solution of oxide of cobalt, is to be edulcorated and reduced to the metallic state in a crucible containing crown glass. Pure nickel in the form of a metallic powder is readily obtained by exposing its oxalate to moderate ignition. (*Ure's Dict. of Arts, &c.*)

NICOLAI'TANS. One of the earliest Christian sects, mentioned in the Revelations of St. John, where the angel of God reproaches the church of Pergamos with harbouring persons of this denomination. They are there characterized as inclining to the licentious and pagan practices of the Gentiles; but the fathers have also accused them of partaking in a great measure of the Gnostic opinions. It is doubtful, however, whether on this point there be not some confusion between the Nicolaitans of the first and the followers of Nicolaus of the second century. (See *Mosheim* (transl. 1790.), i. 143. *Gieseler's Text Book* (transl.), i. 69.)

NICOTI'NA. A poisonous alkaline base, extracted from the leaves and seed of the *Nicotiana tabacum*, or common tobacco. It derives its name from Nicot, a Frenchman, who about 1560 first sent tobacco into France.

NICTITA'TION. (Lat. nicto, *I wink.*) Winking of the eyes. This is generally a nervous affection, and very frequently it becomes a trick or habit. Where it arises from any local irritating cause, bathing the eyes with warm water affords relief.

NIDDUI. A sort of minor excommunication among the Hebrews, which continued usually about a month. If not removed within that period, it was prolonged for sixty or even ninety days. If during this term satisfaction was not made, the excommunicated person fell into the *cherem*, which was the second species of excommunication; and afterwards into the *scammatha*, which was the most dreadful of all.

NIDIFICA'TION. (Lat. nidus, *a nest;* facio, *I make.*) The process by which birds construct their nests.

NIE'LLO. (Ital.) A method of engraving on plate. *See* art. ENGRAVING, where the process is described.

NIGHT. (Lat. nox, Ger. nacht.) The part of the natural day during which the sun is below the horizon.

NIGHT HERON. *See* ARDEA.

NIGHTINGALE. A migratory species of Passerines, and the sweetest of song-birds; the type of the subgenus *Luscinia*, which is more closely allied, according to Mr. Blythe, to the thrush family, than to the fauvettes (*Currucidæ*), among which it is placed by Cuvier. The males of the nightingale reach the southern counties of England sometimes in April, but more commonly not till the beginning of May; the females do not arrive till a week or ten days after the males. Migrating from the south, they visit this country for the purpose of breeding, and the famed song of the male is his "love chant," and ceases when his mate has hatched her brood. "Vigilance, anxiety, and caution now succeed to harmony; and his croak is the hush, the warning of danger and suspicion, to the infant charge and the mother bird." If by accident his mate be killed, the male resumes his song; and will continue to chant very late in summer unless he can attract, as he commonly soon does, another female. The nightingale feeds chiefly on the larvæ of insects, which abound at the season of its arrival in this country. The nest is built near the ground; the eggs are four or five in number, of a uniform dark brown colour: the young are excluded in the month of June, and are ready to accompany the parents in their southward migration in the month of August.

NIGHT-JAR. The name of a remarkable British bird, the type of the genus *Caprimulgus*, distinguished by the wide gape of its beak, whence perhaps has arisen the popular idea of its sucking the teats of cattle, and its other common name "goat-sucker," the equivalent of which it has received in most European languages, and which Linnæus has continued in its generic designation. It is scarcely necessary to observe that the structure of the bill renders the act of sucking impracticable in the night-jar or any other bird. The genus *Caprimulgus* is characterized by a wide and deeply-cleft beak, armed with strong bristles, and capable of engulphing the larger insects; the nostrils placed at its base are like small tubes; the wings are lengthened; the feet short, feathered to the toes, which are connected together by a membrane at their base; the claw of the middle toe is commonly pectinated at the base. The night-jars are most active and hunt their prey in the dusk; they have the same light and soft plumage as other nocturnal birds. Our common species (*Capr. Europæus*) is remarkable

for the loud sound it emits, like the burr or jarring of a spinning-wheel.

NIGHTMARE. An oppressive sensation and struggle during sleep, otherwise called *incubus* (which see); produced usually by indigestion.

NI'GHTSHADE. *See* DULCAMARA and BELLADONNA.

NIGHT WATCH. A period of the night as distinguished by a change of the watch. Among the Romans the night was divided into four watches, each of three hours' duration, and styled first, second, third, and fourth watches, according to the military usage, by which the guard was relieved four times during the night. The first watch began at six in the evening and lasted till nine, according to our mode of computing time; the second lasted from nine till twelve or midnight; the third from midnight till three in the morning (called *cock-crowing*); and the fourth commenced at three and ended at six, thus completing the twelve hours. The Jews originally divided the night into three watches; but at a later period, and previously to the appearance of our Saviour, they adopted the Roman division of the night, which is frequently alluded to in the New Testament. In the Roman mythology, Nox was the goddess who presided over the night. She is represented clothed with a tunic thickly set with stars; and in her honour the Romans sacrificed a cock during the night.

> Nocte deæ Nocti cristatus cæditur ales,
> Quod tepidum vigili provocet ore diem. OVID.

NI'GRINE. (Lat. niger, *black*.) Silico-calcareous oxide of titanium. It occurs in Ceylon and Transylvania.

NI'MBUS. (Lat.) In Painting and Sculpture, a circular disk round the heads of divinities, and sovereigns and saints.

NIMBUS CLOUD. In Meteorology. *See* CLOUD.

NI'NSIN ROOT. A bitter root, possessed of the medicinal qualities of ginseng. It is the root of the *Sium ninzi*.

NI'NTH. In Music, one of the dissonant intervals in music, being properly the second double.

NI'OBE. In Classical Mythology, daughter of Tantalus, and one of the Pleiades, married to Amphion, king of Thebes. Proud of her numerous and flourishing offspring, she provoked the anger of Apollo and Diana, who slew them all: she was herself changed by Jupiter, in Phrygia, into a rock, from which a rivulet, fed by her tears, continually pours. The subject of Niobe and her children was a great favourite with the poets of antiquity. Besides the beautiful story in Ovid (*Met.* vi. 146.), there are numerous epigrams in the Greek *Anthology*, which appear to be descriptive either of the group of figures to which we refer below, or to some similar group. See more especially that beginning,

> Ταντᾰλε και Νιοβα κλυ' εμαν φατιν αγγελον ατας.

This fable has also afforded a subject for art, and particularly for the sculptor of the beautiful group in the tribune at Florence, known by the name of Niobe and her Children. Some antiquaries attribute it to Scopas: Winkelman inclines to believe it the workmanship of Praxiteles. It is beautifully characterized by Hazlitt, in his "Treatise on Art," in the *Ency. Britannica*.

NI'PPERS. In Sea language, small ropes or selvages for attaching the messenger to the cable.

NI'SI PRIUS. In Law, a term originating in a legal fiction, when the pleadings in a cause in one of the superior courts of common law (*see* PLEADING) are concluded, and an issue of fact is raised between the parties. The issue is appointed, by the entry on the record or written proceedings, to be tried by a jury from the county, of which the proceedings are dated, at Westminster, *unless before* the day appointed (nisi prius) the judges shall have come to the county in question. The judges of assize, by virtue of their commission of nisi prius, try the causes thus appointed on their several circuits, unless they are dated of London or Middlesex; in which case they are tried in London or in Westminster, at the sittings during or after term. *See* COURTS, SUPERIOR; and TERM.

NITRA'TES. Salts of the nitric acid; thus *nitrate* of potassa is a compound of one atom of nitric acid and one atom of potassa. *See* NITRE.

NI'TRE, *Nitrate of Potassa, Saltpetre*. This salt consists of 54 nitric acid + 48 potassa; its equivalent, therefore, is 102. It is spontaneously generated in the soil, and crystallizes upon its surface in several parts of the world, especially in India, whence nearly the whole of the nitre used in Britain is derived. It has occasionally been produced artificially in *nitre beds*, formed of a mixture of calcareous soil with animal matter; in these nitrate of lime is slowly formed, which is extracted by lixiviation, and carbonate of potash added to the solution, which, by double decomposition, gives rise to the formation of nitrate of potash and carbonate of lime: the latter is precipitated; the former remains in solution, and is obtained in crystals by evaporation. Nitre crystallizes in six-sided prisms, soluble in seven parts of cold water and in less than its weight of boiling water. It has a cooling saline taste, and is anhydrous. At 616° it fuses, and at a red heat is decomposed. Its great use is in the manufacture of gunpowder, and in the production of nitric acid. It is also employed in the preservation of meat.

Nitrate of soda crystallizes in rhombic crystals; hence termed *cubic nitre*. It is found plentifully in Peru, and is imported into England from America. It is used as a manure and as a source of nitric acid, but, being slightly deliquescent, it cannot be employed in the manufacture of gunpowder.

Nitre has sometimes been mistaken for Glauber's salt, and, when taken in the quantity of half an ounce or an ounce, it acts as a powerful poison. In such cases the stomach should be evacuated as rapidly as possible, and the symptoms of spasm relieved by opiates. In doses of 5 to 15 grains it is diuretic and diaphoretic.

NITRIC ACID. This acid is a compound of 1 atom or equivalent of nitrogen = 14, and 5 of oxygen (8×5) = 40; hence its equivalent in the dry or anhydrous state, as it exists, for instance, in nitre, is $14 + 40 = 54$. As it usually occurs in the liquid state, it is a compound of 1 equivalent of dry acid, 54, and 2 of water (9×2), 18; hence the equivalent of the liquid acid is 72. It is commonly known in commerce under the name of *aqua fortis*, and is prepared by distilling a mixture of sulphuric acid and nitre. It is commonly yellow, or even deep orange coloured; but it may be deprived of nitric oxide, which occasions this colour, by heat, and is then colourless. It is intensely corrosive and sour, fumes when exposed to air, and has a specific gravity of 1·50 when in its utmost state of concentration. It boils at 248°, and freezes at −50°. It is a most powerfully oxidizing agent, and is decomposed with more or less rapidity by almost all the metals.

The salts which it forms are called *nitrates;* they are all soluble in water; they are decomposed by heat, and, when mixed and gently heated with sulphuric acid, they evolve nitric or nitrous acid.

NI'TRIC OXIDE, or NITROUS GAS. This gas was discovered by Hales, and more accurately studied by Priestley. It is obtained during the action of nitric acid diluted with about two parts of water upon metallic copper; it is copiously evolved, and may be collected over water. 100 cubical inches of this gas weigh between 32 and 33 grains; its density, therefore, compared with air, is 1037. It is at once easily recognized by forming orange-coloured fumes whenever it escapes into the air or comes into contact with oxygen, so that this gas and oxygen are excellent tests of each other's presence. It consists of equal volumes of nitrogen and oxygen, or of 1 equivalent of nitrogen and 2 of oxygen; hence it is termed a binoxide or deutoxide of nitrogen. The respective weight of its components, therefore, are 14 nitrogen + 16 oxygen, and the equivalent of the gas is 30.

NITRI'TES. Salts of the nitrous acid; thus *nitrite* of potassa is a compound of 1 atom of nitrous acid and 1 atom of potassa, &c.

NI'TROGEN. (Gr. νιτρον, and γεννασιν, *to produce*.) A simple gaseous body which forms a constituent part of nitric acid, and which, being unrespirable, has also been termed *azote:* from α, privative, and ζωη, *life*. It was identified as a peculiar gas by Dr. Rutherford in 1774, and shown to be one of the components of atmospheric air by Lavoisier in 1774. It is generally obtained by burning a piece of phosphorus in a jar full of air inverted over water. The phosphorus during its combustion combines with the oxygen of the air to form phosphoric acid, which is dissolved by the water, and the remaining element of the air, namely, the nitrogen, remains. Nitrogen is a colourless, inodorous, and tasteless gas, not absorbed by water, and having no action on vegetable colours. It extinguishes all burning bodies, and is itself uninflammable. It is a little lighter than atmospheric air, 100 cubic inches weighing 30·16 grains. Its equivalent is 14, and it combines with oxygen in 5 proportions, giving rise to the following compounds:—

	By volume. N. O.	By weight. N. O.	Equiv.	Symbols.
1. Nitrous oxide	$100 + 50$	$= 14 + 8$	$= 22$	$= n + o$.
2. Nitric oxide	$100 + 100$	$= 14 + 16$	$= 30$	$= n + 2\,o$.
3. Hyponitrous acid	$100 + 150$	$= 14 + 24$	$= 38$	$= n + 3\,o$.
4. Nitrous acid	$100 + 200$	$= 14 + 32$	$= 46$	$= n + 4\,o$.
5. Nitric acid	$100 + 250$	$= 14 + 40$	$= 54$	$= n + 5\,o$.

NI'TROMURIA'TIC ACID. Nitrohydrochloric acid of modern nomenclature. The mixture of nitric and of muriatic (or hydrochloric) acid; formerly called *aqua regia*, from its solvent power over gold, the *king* of the metals.

NITRONA'PTHALASE. A compound resulting from the action of nitric acid on napthalin: a modification of it has been termed *nitronapthalese*.

NITROSA'CCHARIC ACID. By the action of sulphuric acid on gelatine a peculiar saccharine matter is formed, which combines with nitric acid, and forms a crystallized acid designated as above.

NITROSULPHU'RIC ACID. An acid resulting from the mixture of one part of nitre with eight or ten parts of sulphuric acid. It was originally proposed by Mr. Keir as a useful agent for separating the silver from the copper of old plated goods. At the temperature of about 200° it dissolves silver, while it scarcely acts upon copper or lead, unless diluted, or at higher temperatures.

NI'TROUS ACID. When two volumes of nitric oxide and one of oxygen are mingled in an exhausted glass globe they form a dense orange-coloured vapour, which may be liquified by cold, and which is *nitrous acid*. Its elements are so condensed that 1 volume of nitrogen and 2 of oxygen form 1 volume of nitrous acid vapour, the specific gravity of which is 3·17. The presence of this vapour renders nitric acid red and fuming, in which state it is commonly termed *nitrous* acid.

NI'TROUS OXIDE. Protoxide of nitrogen; a gas obtained by heating nitrate of ammonia, which salt is thus resolved into nitrous oxide gas and water. When nitrous oxide is respired, it produces effects somewhat similar to those of intoxication; hence it has been called *laughing gas*.

NIZAM. The title of one of the native sovereigns of India, between whom and the East India Company many subsidiary treaties exist. This title is derived from Nizam-ul-Mulk, who in the beginning of last century obtained possession of the Mohammedan conquests in the Deccan; his successors in the sovereignty having assumed his name as their title of dignity, which they have retained to this day.

NOBILISSIMUS, was a title of dignity given to the princes of the imperial family of Rome. It is said by Doucine to have originated with Justin, but others hold it to be of much more ancient date.

NOBI'LITY. The general appellation for a distinguished order of society which exists in every civilized country, with the exception of the United States and Norway. (*See* PEERAGE.) In Roman antiquity persons were not noble by birth, but in consequence of the public offices held by their ancestors, who had the sole right to bequeath their images to their descendants (*jus imaginum*). (*See* HERALDRY.) Originally the patricians were the only nobles, they alone being eligible to the magistracy; but when the *equites*, and even the *plebs* were admissible, the great body of the nobles began to be formed. The first in any family who was raised to a curule dignity was styled *novus homo*. *See* NOVI HOMINES.

NO'BLE, an English coin of the middle ages, value 6*s*. 8*d*., current in the reign of Edward III. According to Knighton, the *rose noble* was a gold coin in use about the year 1344.

NOCTHORA. *See* SAGOUIN.

NOCTILU'CA. A term applied by Boyle and some of the older chemical philosophers to phosphorus.

NOCTU'RN. (Lat. nox, *night*.) An office consisting of psalms and prayers, celebrated in the Roman Catholic church at midnight, after the example of David (Ps. 118.). It was said to have been introduced into the West by St. Ambrose. It now forms part of the service of matins.

NOCTU'RNALS, *Nocturnæ*. (Lat. *nox*, night.) A tribe of Raptorial birds, including those which fly by night, and have the eyes directed forwards: also a family of Lepidopterous insects, which, in like manner, are active chiefly in the night season.

NODE, in Surgery, is a hard tumour upon a bone, which creates considerable pain, and often is attended by caries or necrosis. They are most common upon the tibia and bones of the head and fore-arm, where they are thinly covered by flesh.

NODES, in Astronomy, are the two points in which the orbit of a planet intersects the plane of the ecliptic. The point in which the centre of a planet passes from the south to the north side of the ecliptic is called the *ascending node*, and in astronomical computations is usually indicated by the symbol ☊; the opposite point, or that in which the planet passes to the south side of the ecliptic, is called the *descending node*, and is indicated by ☋. The straight line which joins these two points, formed by the intersection of the plane of the planet's orbit with the plane of the ecliptic, is called the *line of the nodes*. The nodes of the lunar orbit were anciently called the head and tail of the dragon.

The position of the nodes on the ecliptic is one of the elements by which the situation of the plane of an orbit in space is defined: in fact, it is easy to see that, if the position of the line of the nodes, and also the inclination of the orbit to the ecliptic, be known, the position of the plane of the orbit is entirely determined. The two nodes being distant 180°, it is only necessary to indicate the position of one of them: the longitude of the ascending node, or its distance from the first point of Aries, is the element used by astronomers. In all the planetary orbits the line of the nodes is variable, having a retrograde motion from east to west in respect of the fixed stars, but so slow that it amounts only to a few seconds in a year. The regression of the moon's nodes is very considerable, as it completes a revolution in about 19 years. (*See* MOON.) This retrograde motion of the nodes of all the planets is a necessary consequence of their mutual attractions. For the positions and variations of the nodes of the different planets, see PLANET.

NO'DULE. (Lat. nodus, *a knot*.) Rounded irregular lumps or masses.

NO'DUS. In Botany, a point situated upon the axis of a plant, whence a leaf or leaf-bud originates.

NOËL. The French name of Christmas Day, derived either from *dies natalis* (Lat. *birthday*), or from an abbreviation of the word Emmanuel.

NOE'TIANS. In Ecclesiastical History, a sect so called from Noetus, an Ephesian, the master of Sabellius. They acknowledged only one person in the divinity; and, consequently, were accused of maintaining that God the Father had suffered on the cross. *See* PATRIPASSIANS.

NOGGING. In Architecture, brickwork carried up between upright pieces or quarters.

NO'GGING PIECES. In Architecture, the horizontal pieces of timber fitting in between the quarters, to which they are nailed in a brick-nogged partition, which they serve to steady and strengthen.

NO'LI ME TA'NGERE, in Surgery, is a disease of the skin, commencing with small ulcerations which destroy the part. They sometimes affect the cartilage of the nose, which is destroyed by their progress; almost all applications rather increase the progress than allay it.

NO'LLE PRO'SEQUI. In Law, an acknowledgment or agreement by the plaintiff in a suit that he will not further prosecute it, either as to the whole or a part of the cause of action (as, for instance, where, on the defendant's demurring to one count in a declaration, the plaintiff enters a nolle prosequi as to that count, and proceeds to trial on the other counts); or as to one or more out of several defendants.

NO'MADES. (Gr. *νομαδες*; from *νομος*, *pasture*.) Tribes of men without fixed habitation. The nomades of classical times were generally tribes devoted to pastoral pursuits; for the ancients knew of no races of savages subsisting wholly by the chase. The principal nomadic tribes of antiquity were those of southern Russia and the interior of Asia, from whom sprung, in the decline of the Roman empire, many of the tribes which overran western Europe; and, at a later era, those which conquered empires in western and southern Asia.

NOME. (Gr. *νομος*; from *νεμω*, *I divide*.) The Greek name for the provinces into which Egypt was divided from the most remote antiquity. According to Diodorus Siculus, the division into nomes was performed by Sesostris, whom some modern writers consider as identical with the Remeses II. of the monuments; but it is supposed to have subsisted from the time of the earliest Pharaohs. There were 36 nomes, which, in the time of Strabo, were thus divided: — 10 in the Thebaïd, 16 in the Heptanomis, or intermediate district (which, according to its name, probably consisted in earlier times of 7 only), 10 in the Delta. This division was not materially altered until the latest age of the Roman government. (See D'Anville, *Mémoires sur l'Egypt*; *Wilkinson's Manners and Customs of the Ancient Egyptians*, vol. ii.)

NO'MENCLA'TOR. An officer employed by the candidates for the great state offices of Rome, to accompany them through the streets and whisper them the names of such citizens as they might meet, in order that they might then address them by name, and canvass their votes. It is derived from Lat. nomen, and the old word calo, *I call*.

NO'MENCLA'TURE, was originally applied to a catalogue of the most ordinary words in any language, with their significations, &c., drawn up for the purpose of facilitating their use and retention to those who are endeavouring to acquire a language. But, in a more general sense, this term is employed to denote the language peculiar to any science or art: thus we speak of the nomenclature of chemistry, botany, &c.

NO'MINALISTS. A term originally applied to a scholastic sect which arose in the 11th century. Its founder was John Roscelin, a churchman of Compiegne, who asserted that general terms have no corresponding reality either in or out of our minds, being, in truth, words, and nothing more (*flatus vocis*). This doctrine naturally excited great consternation among the schoolmen, with whom, hitherto, all that was real in nature was conceived to depend on these general notions or *essences*. Its promulgator underwent much persecution for his opinions, and was ultimately compelled to retract them, as inconsistent with the doctrine of the Trinity as it was then stated. He found, however, an able successor in the person of Peter Abelard, who attracted numerous disciples by his dialectical skill and eloquence, and, with his followers, whom he led in a body to Paris, was the occasion of founding the celebrated university of that city. After his death the ancient realism was restored to its supremacy; nor do we meet with a nominalist until the 13th century, when William of Occam revived his doctrines under some modifications. The last-mentioned philosopher may, in fact, with greater justice, be styled a conceptualist, as he distinctly stated

the formation of general terms to depend on the conditions of thought, and hence to possess a species of subjective reality, as the sign or indication of an actual process of thought, though not either distinct objects of consciousness or realities in nature. Those who hold either of the latter theories are realists. The controversy is one which has excited great attention among modern philosophers, among whom Hobbes and Dugald Stewart may be considered strict nominalists, while Locke and Dr. Thomas Brown style themselves conceptualists. There are, however, expressions in Locke's writings which would rather stamp him as a realist, under the former of the two modifications which we have given above. (See articles SCHOLASTIC PHILOSOPHY, THOMISTS, SCOTISTS.) There are very profound observations on the subject of this controversy in the first volume of *Hallam's Literature of the Middle Ages*. See also *Brucker's Historia Critica Philosophiæ*.

NO'MINATIVE CASE. In Grammar, that form of a noun which names or designates a substance *absolutely*, or without relation to any other substance.

NOMO'CANON. (Gr. νομος, *law*; κανων, *canon* or *rule*.) In Ecclesiastical Law, a work in which canons of the church, and imperial laws touching the same subjects, are collected and compared. The first was made by Joannes Scholasticus (A.D. 551). The most celebrated was that of Photius, patriarch of Constantinople.

NO'MOPHY'LACES. (Gr. νομος, *the law*, and φυλακες, *guardians*.) Among the Athenians, magistrates or legal officers, whose business it was to see that neither the privileged citizens nor the lower classes made any innovation upon the laws. They held seats in all the public assemblies, and during the public games and festivals had chairs erected for them opposite to those of the archons. This was also the appellation of those officers appointed to communicate to the combatants the laws of the Olympic games.

NOMO'THETÆ. (Gr. νομος, *law*, and τιθημι, *I lay down*.) A body of citizens at Athens, chosen by lot out of such as had been judges in the court Heliæa, to the number of a thousand. Their office seems to have been a sort of inspectorship of existing laws, with the duty of proposing amendments.

NO'NÆ ET DECIMÆ. In Ecclesiastical Law, the contributions of tenants of the church were anciently so called: the nonæ, or ninth part, standing for a species of rent, the decimæ for the tithe due to the church.

NONAGE. In Law. *See* INFANT, MINORITY.

NONAGE'SIMAL (Lat. nonagesimus, *the ninetieth*), in Astronomy, is the *ninetieth* degree of the ecliptic, reckoned from either of the points in which it is intersected by the horizon. It is therefore the highest point of the ecliptic at any instant, and its altitude is equal to the distance of the pole of the ecliptic from the zenith. The nonagesimal is used in calculating the parallaxes of the moon.

NO'NAGON. (Lat. novem, and γωνια, *angle*.) In Geometry, a plane figure having nine angles, and consequently nine sides. The area of a regular nonagon is $= \frac{9}{4}$ tan. $70^\circ = 6{\cdot}1818242$, the side being 1.

NON COMPOS MENTIS. (Lat.) In Law, a general term for those afflicted with mental incapacity. *See* LUNACY, IDIOT.

NO'NCONDU'CTOR. This term is generally limited to certain phenomena connected with the transfer of heat and electricity through bodies; those substances which resist the direct passage of those influences (and occasionally also of sound) are called *nonconductors*.

NONCONFOR'MISTS. A general term under which all the religious communities which do not conform to the liturgy of the church established in England may be comprehended. It belongs more properly to the large body of clergy who, at the Restoration, refused to subscribe to the Act of Uniformity, and were in consequence ejected from their benefices on St. Bartholomew's day, 1662. This act was first promulgated by Elizabeth, and required all the clergy to use the *Book of Common Prayer*, and inflicted severe penalties upon any one who should be convicted of speaking or preaching against it. The act of Charles II. contained still stricter provisions, enjoining every beneficed person not only to use the book, but to declare his assent and consent to every part of it; and enacting that unless this were done on a certain day he should be, *ipso facto*, ejected. Other declarations were also to be subscribed; as, "That it is unlawful to take arms against the king on any pretence whatsoever;" "That no obligation from the covenant lies upon himself or any other person." It is said that two thousand persons resigned their preferments in consequence; and even after this their party was subjected to the further infliction of the conventicle acts, which forbade more than five persons besides the family to assemble together in any house for religious worship; and the five mile act, which subjected to penalties and imprisonment any nonconformist clergyman who should take up his residence within five miles of any corporate town, or other place where he had been minister. *See* DISSENTERS.

NONES. (Lat. novem, *nine*.) In the Calendar, one of the three divisions of the Roman month, and so called because they fell on the *ninth* day, reckoned inclusively, before the ides. In the months of March, May, July, and October, the ides fell on the 15th day of the month, and the nones, consequently, on the 7th. In the other months, the ides were on the 13th day, and the nones on the 5th. *See* CALENDAR, CALENDS, IDES.

NON EST INVENTUS. (*He is not found.*) In Law, the formal Latin words anciently used in the sheriff's return to a writ of capias, that the defendant was not to be found within his bailiwick.

NO'NIUS. A name frequently given to that useful contrivance, the vernier, for subdividing the divisions of graduated arcs or scales into minute parts, from its invention having been erroneously ascribed to Pedro Nunez, or Nonius, a Portuguese, who lived in the early part of the 16th century. The contrivance employed by Nonius was widely different from the vernier now universally used. It consisted in describing within the same quadrant 45 concentric arcs, dividing the outermost into 90 equal parts, the next into 89, the next into 88, and so on, the innermost being consequently divided into 46 only. With this instrument the observed altitude of an object could be read off on the outermost arc only to degrees, but the fractions were obtained in the following manner: — The plumb-line, or moveable index, must intersect one of the concentric arcs at, or very near, a point of division. Now, it is evident that the number of parts read off at this point must be in the same proportion to the degrees and fractions of a degree intercepted on the outermost arc, as the number of parts into which the arc containing the point is divided, is to 90°. The division read off being therefore multiplied by 90, and divided by the number of parts in the arc, gives the observed altitude to fractions of a degree. Thus, if the plumb-line intercept 25 parts exactly on the arc in which the number of parts is 78, the angle measured will be $28{\cdot}846^\circ$: the fraction is easily converted into minutes and seconds. Nonius supposed that this artifice was known to Ptolemy. It was adopted by Tycho Brahe; but soon abandoned by him for the method of diagonal divisions, in consequence of the difficulty of dividing accurately the different arcs. (*Robins's Mathematical Tracts*, vol. ii.) *See* VERNIER.

NON-JU'RORS. In English History, that party among the clergy of the national church who refused to take the oath of allegiance to the new government after the Revolution. As many of these clergy, at the same time that they opposed a conscientious resistance to the usurpations of James II. had nevertheless continued to preach submission to his authority, on the principle of his divine right by hereditary succession to the obedience of his subjects, it became impossible for them with consistency to submit to a monarch crowned only by authority of parliament. It was therefore much desired by many friends of the new government to make some exception in their favour, and relieve them from the necessity of taking the oaths; not an amendment made by the House of Lords in the act requiring this oath, which purposed to excuse the clergy from taking it unless called on by the privy council, was rejected by the Commons. Eight bishops, including the primate Sancroft, with about four hundred clergy, were in consequence excluded from their sees and benefices. The original non-jurors were peaceable and honest men for the most part; but many of them soon became implicated in all the violence of the Jacobite faction. *See* JACOBITES, PRETENDER.

NON-NA'TURALS. A term applied by the old physicians to certain matters which are necessary to life, but do not form a part of the living body; such as air, food, excretions, sleep, &c.

NONPARE'IL. *See* PRINTING.

NON-RESISTANCE, THE DOCTRINE OF, in Politics, is that which inculcates the unlawfulness, on religious grounds, of resistance by force to the commands of a prince or magistrate. This is strongly laid down by the inspired writers, and especially by St. Paul, in the 13th chapter of his Epistle to the Romans. In the ordinary acceptation of the doctrine, it is taken to enforce the duty of obedience to the lawful commands of magistrates. But, in that peculiar sense which is attached to it in English constitutional history, it means unqualified obedience to every command, especially of the prince or supreme magistrate, whether lawful or not; and consequently condemns all forcible opposition even to tyranny or usurpation. But the advocates of non-resistance, in this extended sense, do not appear to have ever contended that it applied to commands of inferior magistrates in the same sense and degree as to those of the highest: they therefore supposed a peculiar sanctity in the person and office of the ruler which no other officer possessed; and thus combined the doctrine of divine right with that of passive obedience or non-resistance. These doctrines are plainly laid down in the homilies of the church of England; in which, in the phrase of Bolingbroke (*State of Parties*), they *skulked* until the reign of James I. (See especially that *On Wilful Disobedience and Rebellion.*)

But in that reign they were more generally avowed by the learned and loyal; and in 1622 the University of Oxford sanctioned them by a solemn decree. The events which led to and followed the great rebellion naturally led men's minds to pay greater attention to the speculative part of politics; and, while Hobbes was framing a theory of absolute monarchy on the principle of the social contract, a different class of reasoners arrived at the same result through a peculiar interpretation of scripture. Sir Robert Filmer (especially in his *Patriarcha*), Bishop Sanderson, and others, made the regal power originate in the patriarchal; and endeavoured to prove that all other forms of government, being unrecognized by scripture, were usurpations. Dean Sherlock, the ablest writer of the school of divine right (see his *Case of Resistance to Supreme Powers*, 1684), endeavoured to prove the absurdity of the theory of the social contract, and to show from scripture the unlawfulness of resisting any command, even of an usurping power. It is in answer to these reasoners that *Locke's Essay on Government* was written. In it he confutes the arguments for unqualified non-resistance, by showing that scripture and reason make no distinction between inferior and superior magistrates, and reducing his opponents to the absurdity of affirming that any command, however extravagant, of the lowest magistrate, must be obeyed. In 1683, the University of Oxford pronounced its second decree in favour of the tenets of divine right and non-resistance. But the current of court opinion changed at the Revolution. The doctrine of non-resistance was almost proscribed; but maintained by the non-jurors, who professed to *obey* the usurping government, while they refused to *recognize* it. In 1709 it was preached by Sacheverell, with the apparently inconsistent result of a riot. His sermon, together with the Oxford decree, were burntby order of the House of Lords. But the doctrine is at this day frequently asserted by the high church party. (See *Dr. Pusey's Sermon on the 5th of November*, 1838.)

NO'NSUIT, in Law, is the renunciation of a suit by the plaintiff. It is either adjudged, in consequence of certain neglects or delays in the prosecution of the suit, or it is voluntarily elected by the plaintiff. It is usual to call on the plaintiff, when he is unable to make out a case to support his pleadings for default of the necessary evidence, and the jury are about to give their verdict, to elect, if he pleases, to abandon his prosecution and submit to a nonsuit, upon payment of costs. The effect of which is, that as a nonsuit is not, except in certain cases, a peremptory bar, he is able to bring another action afterwards for the same cause.

Judgment as in case of a nonsuit, arises from the statute 14 G. 2. c. 17., which enacts that where any issue is joined in an action in the courts of record at Westminster, and the plaintiff has neglected to bring the issue to be tried, the court may, unless it sees reason for allowing the plaintiff farther time, give judgment for the defendant as in case of a nonsuit, which has the same force as a nonsuit, both as to costs and as to its effects on the action.

NOOTH'S APPARATUS. A series of three glass vessels, placed vertically, for the purpose of impregnating water with carbonic acid gas. The lower vessel contains the marble and muriatic acid for the evolution of the gas; the central vessel holds the water through which it is made to pass, under the pressure of the column of water in the third or upper vessel, which is closed by a conical stopper, which serves as a safety valve.

NO'PAL. The *Cactus opuntia*. The plant upon which the cochineal insect chiefly breeds.

NORFOLK CRAG. A tertiary formation which rests on London clay or chalk, and includes marine shells. A line drawn from Cromer on the northern coast of Norfolk to Wayburn, about six miles west, and thence extending southerly about eighteen miles towards Norwich, includes all the regular beds of this rock. *See* GEOLOGY.

NO'RMAL. (Lat. norma, *a rule*.) An adjective signifying that the ordinary structure peculiar to a family, a genus, or a species, is in nowise departed from.

NO'RMAL. A term sometimes used for perpendicular. In the geometry of curve lines, the normal to a curve at any point is a straight line perpendicular to the tangent at that point, and included between the curve and the axis of the abscissa.

NORMAN ARCHITECTURE. *See* ARCHITECTURE, and ENGLISH ARCHITECTURE.

NORNS. In Scandinavian Mythology, the three Fates, equivalent to the Moirai of the Greeks. Their names were Urd, Wörand, and Skuld; or *Past*, *Present*, and *Future*. They were represented as endowed with great beauty, but of a melancholy and sombre disposition; they were consulted even by the gods, and their decrees were sure and irrevocable.

NO'RROY. *See* KING AT ARMS, HERALD.

NORTH. (Germ. nord.) In Geography, one of the four cardinal points of the horizon; that which in European latitudes is opposite the sun at mid-day.

NORTHERN LIGHTS. The name popularly given to the *aurora borealis*.

NO'RTHING, in Navigation, is the difference of latitude made by a ship in sailing northwards.

NOSING OF A STEP. In Architecture, the projecting rounded edges of the tread of a step.

NOSO'LOGY. (Gr. *νοσος, a disease*, and *λογος, a discourse.*) The doctrine of diseases. The term is generally applied to the classification and nomenclature of diseases, and to their general methodical arrangement. *See* DISEASE.

NOSTA'LGIA. (Gr. *νοστεω, I return*, and *αλγος, grief.*) A species of melancholy, resulting from absence from home and country.

NOSTRUM. (Lat.) Literally, *our own;* applied to quack medicines retained for profit in the hands of the inventor or discoverer, or of his assignee.

NO'TABLES. In French history, the deputies of the states under the old régime, appointed and convoked on certain occasions by the king. In 1786 this assembly was summoned, 160 years after its last meeting, and proposed various reforms in different branches of the government: it again met, for the last time, in 1788.

NO'TACA'NTHA. (Gr. *νωτος, the back*, and *ακανθα, a spine.*) The name of a family of Dipterous insects, comprehending those in which the upper part of the thorax or scutellum is armed with teeth or spines.

NO'TARIES, APOSTOLICAL AND IMPERIAL. Public notaries appointed by the popes and emperors, in virtue of their supposed jurisdiction over other powers, to exercise their functions in foreign states. Edward II. forbade the imperial notaries to practise in England. Charles VIII. of France, in 1490, abolished both these classes of notaries, and forbade his lay subjects to employ them.

NO'TARY, or NOTARY PUBLIC. In English Law, one who publicly attests documents or writings, chiefly in mercantile matters, to make them authentic in a foreign country; protests foreign bills of exchange, and the like. The statutes 41 G. 3. c. 79. and 3 & 4 W. 4. c. 70. regulate the admission of notaries in England. In London, they must have been apprenticed seven years to a notary before such admission.

The name notary, among the Romans, appears to have signified a short-hand writer, and to have denoted originally the persons who acted in that capacity, especially at meetings of the senate. Afterwards, the notarii were secretaries to courts, officers, &c. In modern Europe, the notary is an officer whose attestation is necessary to the validity of certain instruments; and his duties are more or less important in different countries. In France, the notary is the necessary maker of all contracts, &c. where the subject matter exceeds 150 francs; and his instruments, which are preserved and registered by himself, are the originals, the parties retaining only copies. The presence and administration of a notary is also essential to the division of lands or goods of inheritance.

NOTA'TION (Lat. notatio), is defined by Dr. Johnson to be "the act or practice of recording any thing by marks, as by figures or letters."

Mathematical notation embraces two distinct subjects; namely, symbols of number and quantity, and symbols of operation. The system of numerical notation adopted in all European countries depends on the very refined idea of giving to each symbol a *local* as well as an absolute value. A refinement of this sort could only have been adopted by a people considerably advanced in the arts of civilization; but though the present system has been traced to the Hindus, among whom it appears to have been in use two thousand years ago, the epoch and country of its origin are entirely unknown. It is probable that the first numeral characters consisted simply of strokes or straight lines, which could be easily cut in wood or stone, and would be alike intelligible to all nations. Such characters are, in fact, preserved in the Roman notation with very little change. Thus, assuming a perpendicular line | to signify *one*, two lines | | would express *two*, the addition of a third | | | *three*, and so on till the reckoner had reached *ten*, which completed the first series of the numerical scale. He might then be supposed to throw a dash across the last stroke or unit to mark the completion of the series; and thus X would come to signify *ten*. The continued repetition of this mark would denote *twenty*, *thirty*, and so forth, till he arrived at a hundred, or *ten* tens, which completes the second series, and might be denoted by adding another dash to the mark for ten, or by merely connecting three strokes, thus ⊏. The repetition of this symbol would in like manner indicate the successive hundreds, the *tenth* of which would be marked by the addition of another stroke, so that four combined strokes ΛΛ would express a thousand. Such were the symbols originally employed in the Roman notation; in process of time it would be perceived that the inconvenience in writing, arising from so many repetitions of the same character, might be avoided, by adopting symbols for the intermediate numbers; and those were furnished by the division of the

symbols already in use. Thus, having parted in the middle the two strokes X, either the under half Λ, or the upper half V, was employed to signify *five*. Next, the mark ⊏ for a hundred was divided into Γ or L, either of which represented *fifty*. Again the four combined strokes having come, in the progress of the arts, to assume a round shape ↀ, was frequently expressed thus (|); and this last form, by partition, gave the two portions (| , or |), to represent *five hundred*. (*Leslie's Philosophy of Arithmetic*, Introd.)

The numeral notation of the Greeks, though far less convenient than that now in use, was formed on a perfectly regular and scientific plan, and could be used with tolerable effect as an instrument of calculation, to which the Roman system was totally inapplicable. They divided the twenty-four letters of their alphabet into three classes, and, by adding another symbol to each class, they had characters to represent the units, tens, and hundreds.

Thus, instead of the digits 1, 2, 3, 4, 5, 6, 7, 8, 9, they represented the units by the letters α, β, γ, δ, ε, ϛ, ζ, η, θ: the tens were denoted by ι, κ, λ, μ, ν, ξ, ο, π, ϟ; and the hundreds by ϱ, σ, τ, υ, φ, χ, ψ, ω, ϡ.

To represent the thousands they employed the first series with the iota subscribed, ͵α, ͵β, ͵γ, ͵δ, ͵ε, ͵ϛ, ͵ζ, ͵η, ͵θ. With these symbols they could express any number under 10,000; thus ͵θϡϟθ, denoted 9999; ͵ηλγ, denoted 8033; ͵δα, 4001, and so with the others. To denote the myriads they made use of the initial letter M, writing the number over it. Thus, $\overset{\alpha}{M}$, $\overset{\beta}{M}$, $\overset{\gamma}{M}$, &c., corresponded respectively to 10,000, 20,000, 30,000, &c. $\overset{\lambda\eta}{M}$ expressed thirty-eight myriads, or 380,000; $\overset{\delta\tau o\beta}{M}$ was equal to 43,720,000; so that the letter M placed under any number produced the same effect as is produced in our system by writing four ciphers to the right of the number. Diophantus and Pappus expressed the myriads more simply by a point after the number: thus, ͵δτοβ·ηκε denoted 43,728,025; and in this manner they proceeded to 9999·9999, or to any number under 100,000,000, which was the extent of their notation before the time of Archimedes, who showed how it might be extended indefinitely. By assuming 100,000,000, or the square of the myriad, as a new unit, and taking this any number of times capable of being expressed by the previous notation, he could represent any number which is expressed in the modern notation by sixteen digits. Assuming, again, the number which in our system is denoted by 1 with sixteen zeros as a second new unit, he was enabled to express any number consisting of twenty-four digits. This method can obviously be continued to any length. A great improvement was afterwards introduced by Apollonius, who proposed the simple myriad, instead of its square, for the root of the system; and thus any large number was constituted of periods of four characters, the first of which, on the right hand, represented units, the next, towards the left, the number of myriads, the third the square of the myriads, and so on to infinity. The different periods were distinguished by breaks or blanks. In this manner a *local* value was given to the symbols, and a single step only was wanting to assimilate this notation entirely to our own. It only required that to be done for the simple tens which had been done for the myriads or tens of thousands. (For an account of the Greek notation and arithmetic, see Delambre, *Astronomie Ancienne*, tome ii.)

From an inspection of the manuscripts preserved in public libraries, it appears that the Arabians had not generally adopted the denary numerals before the beginning of the 13th century of our era. For several ages after the formation of their empire, they hired Christian scribes to keep their accounts; and though, like most other oriental nations, they wrote from right to left, yet they implicitly followed the Greek mode of ranging the numerals and performing the calculations. It is probable that they derived their knowledge of the Indian digits through the medium of the Persians, but the subject is involved in much obscurity. The epoch at which the denary numerals were introduced into Europe is also uncertain; but it appears to have followed, at no great interval, the Saracen conquests in Spain. Vossius places this epoch about the year 1250; Du Cange thinks they were unknown before the 14th century; and they are very rarely to be found in the dates of any writings before the year 1400. They appear to have been first used by astronomers, and afterwards circulated over Europe in the almanacs.

Symbols of quantity are entirely arbitrary; but the letters of the alphabet may be said to be exclusively adopted by mathematicians. When the quantities belonging to any investigation are numerous, it may be necessary to have recourse to different alphabets; and it is always of very great importance to select such symbols as will most readily suggest the thing signified, as the initial letter of a word, or letters which have acquired a sort of conventional right to be applied to particular purposes. It is unfortunate that so little attention has been paid to this subject, and that some general principles have not been adopted by mathematicians to regulate the choice of symbols, inasmuch as the diversity of notation renders it often a troublesome task to compare with one another different investigations of the same problem, or the results of different methods of analysis. There are, however, a few rules, which, though altogether arbitrary, seem to be recognized by all modern writers of any authority. Thus, in algebra, the letters at the beginning of the alphabet are the symbols of quantities supposed to be known, and those at the end of the quantities sought. In analytical geometry and mechanics, x, y, and z are always used to denote the rectangular co-ordinates of a point in space. In trigonometry, the sides of a triangle are usually denoted by a, b, and c, and the angles opposite by A, B, and C respectively. In astronomy, the Greek letters are most frequently used to represent angles. Indices are usually employed when it is desirable to retain the same letters for the same class of quantities.

Symbols of operation are equally arbitrary with those of quantity, but there is much less diversity in the manner of employing them. The signs + and −, universally used to signify addition and subtraction, seem to have been introduced by Stifelius, a German, as the oldest work in which they are found is his *Arithmetica Integra*, published at Nuremberg in 1544. Stifelius also introduced the character $\surd$, originally r, the initial letter of *radix* (root), to denote the root of a quantity. The sign of equality = was introduced by Robert Recorde, and he gives as a reason that "noe 2 thynges can be moare equalle," namely, than the two parallel lines. In the modern calculus the letters of the alphabet are used as symbols of operation; thus, d for the differential and $\int$ for the integral of a quantity. Finite differences and sums are denoted by the corresponding Greek letters Δ and Σ. The fluxional notation introduced by Newton, and which continued to be used in this country till foreign books began to be more freely imported, after the last war, has at length been entirely abandoned for the differential notation of Leibnitz and the Bernoullis. The former is, in fact, utterly incapable of representing the extremely general processes of modern analysis. (See Notes to the English translation of *Lacroix's Elem. Treatise on the Diff. and Integral Calculus; Lubbock on Notation*, in the *Memoirs Roy. Astr. Soc.* vol. iv.; art. "Notation," *Edinburgh Encyclopædia*.)

NOTCHBOARD. (It. nocchia.) In Architecture, the board which receives the ends of the steps in a staircase so called; because it is notched out to receive the ends of the steps.

NOTE. (Lat. nota.) In Music, a character by which the elevations and depressions of sounds are marked, as well as the swiftness or slowness of their motions.

NOTES (Lat. notæ), in Literature, were originally marks affixed by the critics who reviewed the works of an author to those places which they considered to be spurious or faulty, or which on any other account were worthy of remark. In modern times the meaning of the term has been enlarged, being now used as synonymous with *annotation* or *commentary*. Among the Romans praiseworthy passages were usually marked with LL. (*i.e.* laudabiles loci); and faulty passages indicated by θ, a contraction, or, more properly, a symbol for αθετησιν. (*Per. Sat.* iv. 12.) Among the Greeks, good passages with the letter X, signifying χϱηστον, excellent, and against those which were condemned the word αχϱηστον was written, which Gellius calls *ad notamentum culpæ*.

Notes, in Printing, are — shoulder notes: these are at the top of the page in the outer margin, and contain the book, chapter, or date, or both of them; side notes or marginal notes, which give an abstract of the text, as in acts of parliament; or parallel passages, and different readings, as in the Bible; and bottom notes, or foot notes, which are placed at the bottom of the page, and generally contain commentaries and explanatory annotations.

NO'THING. (*No thing*, the negation of being.) In Mathematical language, the term *nothing* is of frequent occurrence, and denotes either the absence of magnitude in circumstances in which magnitude might have existed, as when equals are taken from equals; or it denotes the limit to which a variable magnitude approaches by continual diminution, as when it is said that a magnitude is susceptible of all values between nothing and infinity.

NOTICE, in Law, is that by which a party is supposed to communicate, or to receive, that presumed or real knowledge which is necessary to affect the receiver with legal liabilities. For instance, when a party proceeds to recover premises by ejectment, notice must be served by him, according to certain prescribed formalities, on the tenant in possession, in order to compel him to come in and defend the action. This is an instance of actual notice. Constructive notice is that which is presumed to arise from certain facts: as, for instance, in equity, a purchaser is presumed to have notice of a suit

pending which may affect the subject matter of the sale, except where, by a late enactment (2 Vict. c. 11.), express notice was rendered necessary.

NO'TODO'NTA. (Gr. νωτος, *back;* ὀδους, *tooth.*) The name of a genus of Lepidopterous insects.

NO'TONECTIDÆ. (Gr. νωτος; νεχτω, *I swim.*) The family of Hemipterous insects of which the water-boatman (*Notonecta*) is the type.

NOTTU'RNO. In Music, originally synonymous with serenade (which see); but applied at present to a piece of music in which the emotions chiefly of love and tenderness are developed. Of modern composers Chopin, Field, and Herg are the most distinguished in this department.

NOUN. (Lat. nomen, *a name.*) In Grammar, that part of speech which denotes a *conception;* in contradistinction to an affirmation or judgment, which is expressed by a *verb*. Nouns are divided into substantives and adjectives; the first denoting real or supposed *substances*, the second qualities or properties conceived as belonging to substances. *See* GRAMMAR.

NOVA'CULITE. (Lat. novacula, *a razor.*) The stone of which hones are made for sharpening razors. It is of a slaty structure, and owes its quality of giving an edge to the metal to the fine silicious particles which it contains.

NOVA'TIANS. The followers of Novatian, a presbyter of Rome, who was stigmatized as a schismatic and heretic, and founded a sect of this name in the 3d century, which continued to flourish to the end of the 5th. The aim of Novatian was to deny readmission into the church to all persons who, in time of persecution, or on other accounts, had once lapsed from the faith. In this extreme severity of sentiment he was opposed by the greater number of the clergy of Rome, and especially by one Cornelius, upon whose election to the see Novatian, who was a disappointed candidate, withdrew from the communion of the majority, and established a society of which he became himself the first bishop. This sect was also known by the title of Cathari, or Puritans, which they assumed to express the high sense they entertained of the excellence attainable by, and necessary to, all professors of Christianity.

NO'VEL. (From the Italian novella, derived from the Latin novus, *new.*) A species of prose fictitious composition.

The Italian novella, of which the best and earliest specimens are those contained in the *Decameron* of Boccaccio, was rather a short tale, turning on an event, or on a series of adventures of humour, pathos, or intrigue, than a novel in the modern acceptation of the term. In its present signification in the English language it seems to express a species of fictitious narrative somewhat different from a romance; yet it would be difficult to assign the exact distinction, and, in the French language, the same name (roman) is used for both; while it differs from a tale merely in the circumstance that a certain degree of length is necessary to constitute a novel.

Although, in fact, the terms novel and romance are often used indifferently, yet they have also often been treated as distinct classes of composition in English literature. Perhaps, if we seek to draw the distinction with as much of accuracy as the subject will admit, we may say that the proper object of a novel is the delineation of social manners, or the development of a story founded on the incidents of ordinary life, or both together. Thus will be excluded from the class of novels, on the one hand, tales of which the incidents are not merely improbable (for this may be the case in a novel), but occurring out of the common course of life, and such as are founded on imaginary times and imaginary manners, tales of supernatural incidents, chivalrous romances, pastoral romances, &c.; and, on the other hand, we must exclude from the same class fictitious narratives, in which the author's principal object is neither the story nor the costume, but which are obviously written with an ulterior view, although their incidents and character may perhaps, in other respects, fall under the definition suggested above. Thus, political, philosophical, and satirical fictions are clearly not to be ranked as novels. But it obvious that no definition can be drawn which shall, on this subject, entirely satisfy the caprices of popular language.

Of the novel, in this confined sense, the works of Richardson, and those of Fielding and Smollet, afforded, perhaps, the first examples in English literature. The first of these authors gave birth to the sentimental novel, the latter two to the comic or humorous. Marivaux, Prévost, &c. spread the former style of composition in France; where, as well as on the Continent generally, it attained a high degree of vogue. The novel of manners, whether comic or serious, has, perhaps, been always a more popular species of fiction in England. It may be doubted whether the historical fiction, to which Sir Walter Scott has given such universal popularity, belongs strictly to the class of novel or romance. By aiming at the delineation of real, although past manners, and by the general turn of the story, it seems to resemble the former; while the romantic character of many of its incidents seems to assimilate it to the latter.

For the general history of prose fictitious composition, see ROMANCE.

NO'VELS. (Lat. novellæ constitutiones, *new constitutions.*) In the Roman Law, supplementary constitutions of some emperors, so called because they appeared after the authentic publications of law made by them. Those of Justinian are the best known, and are commonly understood when the general term is used. The *Novels*, together with the *Code* and *Digest*, form the whole body of law which passes under the name of that emperor.

NOVE'MBER. (Lat. novem, *nine.*) The eleventh month of the Julian year; but the ninth month in the old Roman year, which began with March. *See* CALENDAR, YEAR.

NOVEMSILES. The name given by Romulus to the gods of the Sabines, whom he adopted after the conquest of that people. The term was afterwards applied to those heroes or demigods who, in consequence of their power or virtues, were deified after death.

NOVENNALIA (Lat. novem, *nine*, and annus, *a year*), among the Romans, signified, as the derivation of the term implies, festivals held in honour of the dead every *nine years*.

NO'VICE. (Lat. novitius.) A person admitted into a religious community as an inmate, for the purpose of preparation for becoming a member. The state of preparation is termed *novitiate*. The custom of giving novices the religious dress did not begin until the 12th century. The age of profession is fixed by the Council of Trent at sixteen years. During the period of the novitiate the novice is still at liberty to relinquish his intention. The term *novice* was applied to recruits in the ancient Roman soldiery; from which circumstance it appears to have been borrowed in ecclesiastical usage.

NOVI HOMINES, among the Romans, were such persons as, by their own personal merit, had raised themselves to curule dignities without the aid of family connections. This reproach, as is well known, was addressed by Catiline to Cicero.

NOX. (Lat.) In Mythology, the goddess of night. In the Grecian mythology, she was the daughter of Chaos, the sister of Elpen and Erebus, and the mother of Æther, Hemera, Manatas, Momus, the Fates, &c. &c.; which were all personifications of the natural phenomena life, sleep, death, &c.

NOYADES. (Fr. noyer.) The name given to a peculiar punishment resorted to in the first French revolution. The *noyades* were effected by drawing out a plug inserted in the bottom of a boat in which the wretched victims were launched. The genius of iniquity, says a writer in the *Edin. Review*, often displays itself in the same invention. It will be remembered that when Nero was desirous of despatching his mother, and found himself at a loss for an expedient, Anicatus proposed to him "the model of a ship upon a new construction, framed in such a manner that a part might be withdrawn, and the unsuspecting passenger committed to the waves." (*Tac. Ann.* lib. xiv. ar. 3.)

NOYAU. (Fr.) A delightful liqueur; it is flavoured with bitter almonds, or the kernels of peach stones, and contains prussic acid.

NU'CLEUS. (Lat.) Literally any thing round which matter has accumulated, or to which it is affixed. In Botany, it is used in various significations:—1. The central fleshy pulpy mass of an ovule. 2. That part of a seed contained within the testa, and consisting of either the embryo and albumen, or of the embryo only. 3. In lichens, the disk of the shield, which contains the sporules and their cases. 4. In the language of the older botanists what is now termed by gardeners a *clove;* that is, the secondary bulb of a bulbous plant.

NUCLEUS. In Astronomy, the solid part or body of a comet, as distinguished from its nebulosity. *See* COMET.

NU'CULA. (Lat. nux, *a nut.*) Either the fruit, called otherwise a gland or acorn, or any small, hard, one-seeded pericarp; or the female organ of the plant Chara.

NU'DIBRA'NCHIANS, *Nudibranchiata.* (Lat. nudus, *naked;* branchia, *gills.*) The name of an order of hermaphrodite Gastropodous Mollusks which have the branchiæ exposed on some part of the back.

NU'DIPEDA'LIA. (Lat. nudus, *naked*, and pes, *a foot.*) A religious ceremony among the Greeks, Romans, and other nations, observed on account of some public calamity, as famine, drought, pestilence; in the celebration of which (as the word imports) the votaries appeared with the feet uncovered. In various other religious observances this practice was adopted; thus, the Roman matrons, when they offered up supplications to the goddess Vesta, always walked to her temple barefooted: —

Huc pede matronam nudo descendere vidi. — OVID.

A similar ceremony existed among the Jews.

NU'DITIES. (Lat. nuditas, *nakedness.*) In the Fine Arts, figures entirely divested of drapery.

NUI'SANCES, in Law, are of two kinds: public or common, which annoy the king's subjects in general; and private, which are defined "any thing done to the hurt or annoyance of the lands, tenements, or hereditaments of another." The general remedy for public nuisances is by indictment or presentment; for private nuisances, by action on the case for damages.

NU'LLIPORES, *Nullipora.* (Lat. nullus, *no,* porus, *a pore.*) The name of a family of Lithophytous Polypes, the axis of which presents no visible pores on its surface.

NU'MBER (Lat. numerus), is defined by Euclid to be an assemblage or collection of units or things of the same species. This definition excludes the unit itself, or 1. Newton defines number as the abstract ratio of one quantity to another quantity of the same species; and hence there are three kinds of numbers, namely, integers, fractions, and surds. Number, abstractedly considered, conveys merely the notion of *times* or *repetitions.*

Mathematicians consider numbers under different points of view, or with relation to different properties; and hence arise the various distinctions which have been introduced, as even or odd, whole or fractional, rational or irrational, perfect or imperfect, prime or composite, abundant or defective, &c. Numbers also acquire various denominations from the manner in which they are composed; as triangular numbers, pyramidal numbers, polygonal numbers, &c. (See the respective adjectives.)

The theory of numbers forms one of the most subtle parts of the algebraic analysis. Judging from the fragments which have been preserved, the ancient mathematicians had pushed their researches into the properties of numbers to a considerable extent; but until the invention of algebra, and the introduction of a more convenient notation, the difficulties of the subject could only be partially overcome. The most ancient existing work on algebra is that of Diophantus, and it is devoted entirely to numbers. From the time of Diophantus, who lived in the 3d century, to that of Vieta, Bachet, and Fermat, who flourished in the 16th, no advancement was made in the theory; but the discoveries of these illustrious mathematicians carried it far beyond its ancient limits. Euler was the next from whom it received any considerable extension; he was followed by Lagrange, who added many important theories; and it has received its latest perfection from the hands of Gauss and Legendre. The theory of numbers may be studied in the following works: — the *Arithmetic* of Diophantus, with a Commentary by Bachet, and notes by Fermat, Toulouse, 1670; *Waring's Meditationes Algeb.*; Euler, *Introd. in Anal. Infinitorum, Opuscula Analytica,* and various papers in the *Petersburg Memoirs;* Lagrange, in the *Berlin Memoirs;* Gauss, *Disquisitiones Arithmeticæ,* or the French translation; Legendre, *Essai sur la Théorie des Nombres,* 2d edit. 1808. For the mystical properties of numbers the curious reader may consult *D. S. Boetii Arithmetica,* Parisiis, 1521; *P. Bungi Numerorum Mysteria,* 1591; *Taylor's Theoretic Arithmetic,* 1816.

NUMBERS, BOOK OF. *See* PENTATEUCH.

NUME'NIA. (Gr. νεος, *new,* and μην, *a month.*) Grecian festivals celebrated at the commencement of every lunar month, in honour of all the gods, demigods, and heroes of antiquity. They were observed with games and public entertainments, the expense of which was defrayed by the wealthy citizens. *See* NEOMENIA.

NUME'NIUS. The name under which Cuvier separated the curlews, as a distinct genus, from the other *Scolopaces* of Linnæus. They have a beak arcuated like that of the ibis, but it is more slender, and is cylindrical throughout; the tip of the upper mandible extends beyond the end of the lower one, and projects a little downwards in front of it. The toes are palmated at the base.

NUMERALS. The symbols or characters by which numbers are expressed. *See* NOTATION.

NUMERATION, is the art of classing and expressing numbers. Though the mode of reckoning numbers by *tens* or *decads* has prevailed among all civilized nations, and has become incorporated with the very structure of language, there is nothing in the nature of the subject which rendered its adoption a matter of necessity. Any other number might have been chosen for the root of the numerical scale; and, in fact, if a scale were now to be selected by mathematicians familiar with the properties of numbers, there are several considerations which would lead them to adopt *twelve,* in preference to ten. The selection of ten, therefore, which has been almost universal, implies the influence of some common determining principle; and it is easy to see that it arose from the practice, so familiar in the early stages of society, of counting by the fingers on both hands. In various languages, however, traces are found of an earlier and simpler mode of reckoning. We may suppose the earliest of all to be that of combining units in *pairs.* It is still familiar among sportsmen, who reckon by *braces* or *couples.* To count by *threes* was another step, and has been preserved by the same class of men under the term *leash,* meaning the strings by which *three* dogs, and no more, can be held at once in the hand. The numbering by *fours* has had a more extensive application: it was evidently suggested by the custom of taking, in the rapid tale of objects, a pair in each hand. Our fishermen, who generally count in this way, call every *double pair* (of herrings, for instance) a *throw* or *cast;* and the term *warp,* which has exactly the same import, is employed to denote *four,* in various articles of trade. It is alleged that the Guaranis and Lulos, two of the lowest races of savages inhabiting the forests of South America, count only by fours; at least they express the number *five* by four and one, *six* by four and two, and so forth. The quinary system, which reckons by *fives* or *pentads,* has its foundation in nature, being evidently derived from the practice of counting over the fingers of one hand. It appears, from the relations of travellers, to have been adopted by various savage nations of America; and we learn from Mungo Park that it is practised by the Yolofs and Foulahs of Africa, who designate 10 by two hands, 15 by three hands, and so progressively. It is even partially used in this country among wholesale traders. In reckoning articles delivered at the warehouse the person who takes charge of the *tale,* having traced a long horizontal line, continues to draw, alternately above and below it, a *warp,* or four vertical strokes, each set of which he crosses by an oblique score, and calls out *tally* as often as the number *five* is completed. (*Leslie's Philosophy of Arithmetic.*)

The mode of reckoning by *twelves* or *dozens* may be supposed to have had its origin in the observation of the celestial phenomena; there being twelve months or lunations commonly reckoned in a solar year. It appears in the subdivision of weights and measures, as twelve ounces to a pound, twelve inches to a foot; and is still very generally employed in wholesale business, extending to the second and even the third term of the progression. Thus *twelve* dozen, or 144, make the long hundred of the northern nations, or the *gross* of traders, and twelve times this again, or 1728, make the *double gross.* Traces of reckoning by *twenties* or *scores* remain in our own and other European idioms. The expression *three score and ten* is familiar. The French language has no terms for the numbers in the second series of the denary scale above *soixante,* or sixty. *Eighty* is expressed by *quatre-vingts,* and *ninety* by *quatre-vingts et dix, four twenties and ten.* The inhabitants of Biscay are said still to reckon by the powers of twenty, or the terms of progressive scores; and, according to Humboldt, the same mode of numeration was employed by the Mexicans. *See* ARITHMETIC, BINARY, DUODECIMALS, SEXAGESIMALS.

The primary object of numeration is to find names for the different numbers; and, as there are an infinity of numbers, while the number of words is limited, it became necessary to devise some systematic method of combining a few words, so as to express by means of them any number whatever. It is obvious that when large numbers are to be expressed, the lower scales, as the binary, ternary, &c., would be exceedingly inconvenient, on account of the multitude of words that would be required. On the other hand, as a name is required for at least every unit in the scale, a very high scale would be no less inconvenient. In the denary scale, the nomenclature is sufficiently convenient, and in our language almost perfectly regular. A name is given to the 9 units of the first order; the unit of the second order is *ten;* and, by the different combinations of this word, all numbers are named to 99: eleven and twelve are only *apparent* exceptions. A new appellation is wanted for the unit of the third order, or *hundred.* This suffices till we reach the fourth order, or *thousands;* and might even have sufficed to a hundred *hundreds,* or ten thousand. A thousand thousands is called a million, and a million millions a billion; further continuation is useless.

The second object of numeration is to express the nomenclature thus formed by the combinations of a small number of written symbols. This is most conveniently effected by the very refined artifice of giving to each symbol a *local* as well as an *absolute* value. So that the same symbol, 3 for example, is made to express not only 3 *units,* but 3 *tens,* 3 *hundreds,* 3 *thousands,* &c.; or 3 *tenth parts,* 3 *hundredth parts,* &c., according to its distance towards the left or right from the unit's place in any combination of symbols. *See* NOTATION.

NU'MERATOR, in Arithmetic, is that part of the numerical expression of a fraction which indicates how many of those parts into which the unit is supposed to be divided are expressed. Thus, in the fraction $\frac{7}{12}$, the lower number 12 is the denominator, and shows that the unit is divided into 12 parts; 7 is the numerator, and shows how many of those parts are to be taken.

NUMISMA'TICS. (From the Greek νόμισμα, Latin nummus, *a coin.*) The science of coins and medals. The distinction between these classes of objects is, in modern times, that the coin is struck for the purpose of circulation as money; the medal not as a piece of money,

but as a token commemorative of some person or event. But ancient coins are often termed, in common language, medals. The parts of a coin or medal are, the obverse or face, containing generally the head, bust, or figure of the sovereign or person in whose honour the medal was struck, or some emblematic figure in the coins of commonwealths; and the reverse, containing various figures or words. The words around the border of the coin form what is termed the *legend*, those in the middle the *inscription;* when occupying the lower extremity of the pieces, and separated from the rest by a horizontal line, they are termed the *exergue*.

The earliest Grecian coins which we possess appear to have been nearly of a spherical shape: they contain, on the obverse, some emblems of the particular cities which struck them; and on the reverse, deep indentations made by the puncheon in which the metal was held while the obverse was struck. These marks, or the dye, were soon brought into a more regular shape, sometimes forming a neat square, sometimes a circle. Types were afterwards introduced on both surfaces of the coin, by inserting some small object in one compartment of the dye. Ancient coins have been divided into various historical series, as exhibited in the following table:—

Grecian.	1. Civic.	Of Græcia Propria and the Islands. Of Greek colonies. Of Græco-Asiatic cities.
	2. Monarchic.	Kings of Macedon. Kings of states formed out of the Macedonian conquests: Syria, Egypt, &c. &c.; and the independent princes of Epirus and Syracuse.
Roman.	1. Consular.	Roman asses. Coins of the families.
	2. Imperial.	Roman. Grecian. — Provinces, Colonies, and Municipia.
	3. Medallions.	Grecian. Roman.
Barbarian.	1. European; of Thrace, &c. 2. Asiatic; of Persia, &c. 3. African.	

The objects on Grecian civic coins are either, 1. the emblems of the cities; 2. figures of deities, and their attributes; 3. miscellaneous or general symbols, usurped by many states and cities, usually consisting of warlike objects. The legends on Greek republican coins are either the name of the city or its initial letters; or monograms,—*i. e.* figures forming a portion of the name, in which the characters are so interlaced that a limb of one applies to many.

The earliest coins which bore the heads of princes were those of Macedon, commencing with Alexander the Great, and closing with the extinction of the dynasty of the Lagidæ in the Augustan age. Four principal series of Grecian monarchical coins (either of Greek states, or such as adopted the Greek language and customs) have been formed:—1. Of Macedon; 2. Of Sicily, Caria, Cyprus, Heraclea, Pontus; 3. Of Egypt, Syria, the Cimmerian Bosphorus, Thrace, &c. &c., from the era of Alexander the Great down to that of Christ; 4. Of dynasties which flourished subsequently to the latter era; including some kings of Thrace, Bosphorus, and Parthia, with those of Comagene, Edessa, Judæa; to which may be added some lines of Romanized monarchs, as those of Mauritania. The most beautiful monarchic series are those of the Seleucidæ in Syria, and Ptolemies in Egypt. The unit of the Grecian silver coinage, in point of value, may be considered as the drachma, which is of a size between our sixpence and shilling; the smallest silver coin is the dichalcos, only $\frac{1}{24}$th of the drachma; the largest, the tetradrachma, containing four drachmæ. The commonest gold coin is the didrachma, weighing two silver drachmæ, and in value 20, or 15*s.* sterling. Grecian copper coins are generally small.

The Roman coinage differs from the Grecian in many respects; the greater size of the copper coins in early times, and their superior workmanship in later, the prevailing simplicity of devices, &c., form characteristic marks of difference. In the first period of the republic they were cast. The consular copper coins have separate symbols for the pieces, according to their respective value; as the head of Janus for the *as*, Jupiter for the *semis*, &c. The *as* also bore the impress I, to denote its quality of unity as a measure of value. The name *family coins*, applied to many coins of the republic, arose from the custom of inserting the name of some distinguished family in the field of the coins. A silver coinage was first introduced into Rome 266 B. C. The oldest coin was the denarius, equivalent to ten asses: the earliest of these have the head of Janus, for which that of Rome was afterwards substituted on the obverse, with a variety of symbols on the reverse. The coinage of gold was introduced into Rome sixty years after that of silver: the pieces were, the scrupulum, one third of the denarius in weight; a coin weighing two thirds, and another weighing a whole denarius. Afterwards the chief gold coin was the *aureus* (twice the weight of the denarius), and its parts. The imperial Roman coins form by far the most complete and varied series which we possess of ancient or modern times. The symbols on the reverse have been arranged under four heads: as relating to religion, war, games, and the embellishments of the city, under the numerous subdivisions of these subjects. The obverses contain the portraits of emperors and empresses. The characters on the reverses of the coins are, generally speaking, explanatory of the type; expressing, in a few brief words, the history of some occurrence immediately after which the coin was struck, &c. The legends on the obverse mostly contain titles annexed to the imperial dignity, often expressed in abbreviations productive of not a little obscurity.

Not less than three hundred portraits are preserved in the series of Roman imperial coins. The term *medallion* is applied to those productions of the Roman or provincial mints which, in gold, exceed the size of the aureus; in silver, of the denarius; in copper, of the largest copper coin of ascertained value. It is doubtful whether they were intended for circulation as coins, or struck, like medals among ourselves, as commemorative tokens.

Modern coins present so wide a variety as to render it impossible to include any classification of them within the limits of the present notice. In England, Roman coins were current until the arrival of the Saxons: we have the coins of five out of the seven kingdoms of the heptarchy; among them some small copper coins, the only specimens of that metal coined before the reign of Elizabeth. Coins struck prior to the reign of Charles II. had their devices impressed by the blows of a hammer. The system of lettering on the edges, which was succeeded by graining, was invented in order to obviate the fraudulent practice of clipping and filing the current coin.

NUMMULI'TES. (Lat. nummus, *money*, and Gr. λιθος, *a stone*.) An extinct genus of the order of Molluscous animals called Cephalopoda, of a thin lenticular shape, divided internally into small chambers. These occur so abundantly in some parts of the chalk formation, that the name of nummulite limestone is given to the strata so characterized.

NU'NCIO. An envoy of the pope to the court of an emperor or king to negotiate ecclesiastical affairs. (*See* LEGATE.) Previously to the council of Trent the papal nuncios acted as judges in the first instance of matters which lay within ecclesiastical jurisdiction; but since that time they have formed a kind of court of appeal from the decisions of the respective bishops. This jurisdiction, however, holds good only in those countries which still hold themselves subject to the decretals and discipline of the council of Trent; for in other kingdoms and states, such as France, Austria, Tuscany, &c., which, though Roman Catholic, hold themselves independent of the Roman pontiff in matters of discipline, the papal nuncio has no jurisdiction whatever, and is invested merely with a diplomatic character, like the ambassadors of any secular power. The term *nuncio* is the Italian form of the Lat. *nuntius*.

NU'NCUPATIVE WILL. (Lat. nuncupo, *I name*.) In Law, a will orally delivered by the testator. *See* WILL.

NU'NDINÆ. (Lat. nonus, *ninth*, and dies, *a day*.) The market-days or fairs at Rome were so called, because they recurred every ninth day. On this day the people from the country and neighbouring towns flocked to Rome with the produce of their farms or industry. On that day, also, all public proclamations were made, causes heard, witnesses cited, and judgments given. The nundinæ were originally considered as *dies nefasti*, on which no other business could be done; but, for the convenience of the country people, this prohibition was removed by the *Lex Hortensia*.

NUNS. Female devotees among the Roman Catholics, who, like the monks of the other sex, seclude themselves in religious communities, and make profession of perpetual chastity. *See* MONACHISM.

The origin of this institution is commonly ascribed to St. Syncletica, the contemporary of St. Anthony. Among nuns, as among monks, there are various orders; some abandoning themselves entirely to contemplation and spiritual exercises, but many others to the more active duties of private and public charity.

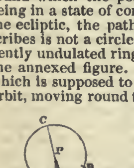
NU'RSERY. In Gardening, a plot of ground, or an entire garden, set apart for the propagation of plants, more particularly trees and shrubs. The situation ought to be open and airy, and the soil of an average quality, neither too heavy nor too light, so as to be adapted to the majority of plants; but in a complete nursery there ought also to be shady borders for plants requiring shade, and beds or compartments of peat-soil, or other peculiar soils, for such plants as are not readily propagated and grown in ordinary soils. Where tender plants are propagated, or where hardy plants are to be raised from seeds or struck from cuttings which are not easily ger-

minated or rooted in the open ground and in the ordinary manner, hot-beds, frames, and hand-glasses are also requisite. Every private garden of any extent requires a nursery to raise and bring forward young plants as a reserve for supplying failures by disease or accident in the general garden; and in every country where private gardens or plantations of trees are frequent, public or commercial nurseries are formed by persons who adopt nursery gardening as a business.

NUTA'TION. In Astronomy, the name given to a small gyratory movement of the earth's axis, in virtue of which, if it subsisted alone without the precession of the equinoxes, the pole of the equator would describe among the stars, in a period of about nineteen years, a small ellipse, having its longer axis equal to 18·5″, and its shorter to 13·74″; the longer being directed to the pole of the ecliptic, and the shorter, of course, at right angles to the longer.

In order to understand the nature of this phenomenon, it is necessary to consider it in connection with that of precession; both depending on the same physical cause, and forming, in fact, essential constituent parts of one and the same great phenomenon. The action of the sun and moon on the protuberant mass about the earth's equator tends constantly to draw the plane of the equator towards that of the ecliptic, or to diminish the angle between them. In consequence of the earth's rapid rotation about its axis, the inclination of the two planes is not permanently altered, but a motion is communicated to the plane of the equator, of such a kind that its axis revolves with a slow conical motion about the axis of the ecliptic; or, which is the same thing, the pole of the equator describes a circle in the heavens about the pole of the ecliptic as a centre, keeping constantly at the same mean distance of about 23° 28′ from it. The direction of this motion is from east to west, and its velocity amounts only to 50·1″ annually, so that the whole circle requires for its description a period of 25,868 years.

Let us now consider what would be the effect of the moon's action independently of that of the sun. The lunar orbit does not coincide with the ecliptic; it is inclined to it in an angle of about 5° 9′; and the position of the line in which the two planes intersect, that is, the line of the nodes, goes back on the ecliptic with a motion which carries it through a complete revolution in about eighteen years and seven months. The axis of the lunar orbit, therefore, also describes a conical motion about that of the ecliptic, or its pole describes a small circle in the heavens about the pole of the ecliptic, at the distance of 5° 9′, and in the same period of about eighteen years and seven months. Now, the effect of the moon's attraction on the parts of the terrestrial spheroid exterior to the inscribed sphere is to produce a slow conical motion of the earth's axis, not about the pole of the ecliptic, but about the pole of the lunar orbit, which is itself in a state of comparatively rapid motion about the pole of the ecliptic. The point, therefore, in the sphere of the heavens round which the pole of the earth's equator revolves, being in a state of continual circulation round the pole of the ecliptic, the path which the pole of the equator describes is not a circle, but a sort of epicycloidal curve, or gently undulated ring. This will be rendered evident by the annexed figure. Let P be the pole of the ecliptic, which is supposed to be fixed; A the pole of the moon's orbit, moving round the small circle A B C D in the space of nearly nineteen years; *a* the pole of the earth's equator, which at each moment moves in a direction perpendicular to the varying position of the line A *a*, and with a velocity varying with the intensity of the acting forces during the revolution of the moon's nodes, but, on the whole, so slow as to carry it round only in 25,868 years. When, therefore, A arrives successively at B, C, D, and E, the line A *a* will take the positions B *b*, C *c*, D *d*, E *e*: the earth's pole will thus, in one tropical revolution of A, have arrived at *e*; and its direction having been always perpendicular to B *b*, C *c*, &c., the path which it will have described will be of the form *a b c d e*. The same thing will be repeated at each succeeding revolution of the moon's node; and it is this alternate increase and diminution of the distances *P a*, *P c*, *P e*, which constitute the phenomenon of the nutation.



As the effect of the sun or moon in giving the earth a motion about its centre of gravity varies with the distance of the attracting body from the plane of the equator, it is evident that the effect of the sun is greatest at the solstices, and is reduced to nothing at the equinoxes. On this account, the obliquity of the ecliptic is subject to a small semi-annual variation, depending on the sun alone. This is called the *solar nutation*. Its existence is, however, only a deduction from the theory of attraction; for its amount, which is less than half a second, is too small to be sensible to observation. The result produced by the combined action of the sun and moon is called the *luni-solar nutation*; though the sensible part of it is produced only by the moon, and follows exactly the period of the moon's nodes.

The uranographical effect of the nutation is to produce a periodical fluctuation of the apparent obliquity of the ecliptic, and of the velocity of the regression of the equinoctial points. Hence arises the distinction between apparent and mean right ascension and declination; the former being given by direct observation, and the latter being the results obtained when the observed places of objects have been cleared of the periodical fluctuations arising from nutation. Formulæ and tables, for the reduction of observations to a common epoch, are given in all works on practical astronomy.

The discovery of the nutation of the terrestrial axis belongs to Bradley, and was a consequence of his other great discovery, the aberration of light. In prosecuting his observations with a zenith sector, with a view to establish his theory of the aberration, he found a greater apparent change in the declinations of stars near the equinoctial colure than could arise from a precession of 50″ in a year; and at the same time exactly the reverse effect in the case of stars near the solstitial colure. In the course of five years, the changes in question amounted, in some instances, to 9″ or 10″; and as it was evident that they could not be explained by any alteration of the quantity of precession, Bradley reverted to an idea which had previously occurred to him, in attempting to account for the phenomenon of aberration. "I suspected," says he, "that the moon's action upon the equatorial parts of the earth might produce these effects. For if the precession of the equinoxes be, according to Sir Isaac Newton's principles, caused by the action of the sun and moon upon those parts, the plane of the moon's orbit being at one time above ten degrees more inclined to the equator than at another, it was reasonable to conclude that the part of the whole annual precession which arises from her action would, in different years, be varied in its quantity; whereas the plane of the ecliptic wherein the sun appears keeping nearly always the same inclination to the equator, that part of the precession which is owing to the sun's action may be the same every year; and from hence it would follow that although the mean annual precession proceeding from the joint actions of the sun and moon were 50″, yet the apparent annual precession might sometimes exceed and sometimes fall short of that mean quantity, according to the various situations of the nodes of the moon's orbit."

A long series of observations on stars situated in different parts of the heavens proved the correctness of this theory; and it was found that all the phenomena were capable of being explained on the hypothesis that the pole of the equator describes a small circle about its mean place, contrary to the order of the signs, and in the same period as that of the revolution of the moon's nodes. Bradley himself afterwards remarked that they would be still more accurately represented by supposing the curve described by the pole about its mean place to be an ellipse instead of a circle. This is confirmed by accurately calculating, from theory, the amount of all the forces which tend to displace the terrestrial equator. The result shows the path of the pole to be an ellipse, and gives nearly the same values of its semi-transverse and conjugate axes as are given by observation. These values were found by Von Lindenau from a series of 810 observations, embracing three complete revolutions of the moon's nodes, to be 80·977″ and 6·682″ respectively. The value of the semiaxis major of the small ellipse imagined by Bradley is called the *constant of nutation*, and enters as an element into all reductions of astronomical observations. Von Lindenau's determination, above stated, is adopted by the German astronomers. The value generally used by British astronomers is 9·25″, which was deduced by Dr. Brinkley, Bishop of Cloyne, from his own observations with the Dublin circle. Very recently this important astronomical element has been investigated by Dr. Robinson of Armagh from the Greenwich observations with the mural circle from 1812 to 1835, and the result at which he arrives is 9·23913″. (*Memoirs Roy. Astr. Soc.* vol. xi. 1840; *Airy's Math. Tracts; Herschel's Astronomy*.) *See* PRECESSION.

NU'THATCH. The name of a shy and solitary bird of the genus *Sitta* (*S. Europæa*). It frequents woods, and feeds on insects chiefly; but also eats the kernel of the hazel nut, which it cracks by fixing it in a chink, and striking it from above with all its force. The nuthatch lays her eggs in holes of trees, and hisses like a snake when disturbed.

NUT OF A SCREW. In Architecture, a piece of wood, iron, or other metal, pierced cylindrically, wherein is cut a spiral groove, adapted to an external cylindrical spiral cut on a bolt. Its use is to screw two bodies together, a head being placed on one end of the bolt to counteract the action of the nut. Two bodies are thus held together by compression, the bolt between the head and the nut being a tie.

NUTRIA, or NEUTRIA. The commercial name for the skins of *Myopotamus Bonariensis* (Commerson), the *Coypou* of Molina, and the *Quoiya* of D'Azara. In France the skins were, and perhaps still are, sold under the name of *racoonda;* but in England they are imported as *nutria* skins — deriving their appellation, most probably, from some supposed similarity of the animal which produces them, in appearance and habits, to the otter, the Spanish name for which is nutria. Indeed, Molina speaks of the *coypou* as a species of water rat of the size and colour of the otter.

Nutria fur is largely used in the hat manufacture; and has become, within the last 15 or 20 years, an article of very considerable commercial importance. The imports fluctuate considerably. In 1823, they amounted to 1,570,103 skins; but they have not in any other year been much more than half that number. In 1826, they were only 60,871. In 1837 and 1838, the imports were, at an average, 358,280 skins a year. Those entered for home consumption pay a duty of 1½*d.* a skin. They are principally brought from the Rio de la Plata. Nutria skins are very extensively used on the Continent. Geoffrey mentions* that, in certain years, a single French furrier (M. Bechem) has received from 15,000 to 20,000 skins.

Like the beaver, the coypou is furnished with two kinds of fur; viz. the long ruddy hair which gives the tone of colour, and the brownish ash-coloured fur at its base, which, like the down of the beaver, is of much importance in hat-making, and the cause of the animal's commercial value.

The habits of the coypou are much like those of most of the other aquatic Rodent animals. Its principal food, in a state of nature, is vegetable. It affects the neighbourhood of water, swims perfectly well, and burrows in the ground. The female brings forth from 5 to 7 at a time; and the young always accompany her.

The coypou is easily domesticated, and its manners in captivity are very mild. (See *Martin*, in the *Proceedings of the Zoological Society*, 1835.)

NU'TRITION. *See* FOOD, DIGESTION.

NUTMEG. The fruit of the *Myristica moschata*, a beautiful tree of the family of the *Laurineæ* of Jussieu, which grows in the Molucca islands. All the parts of this tree are very aromatic; but only those portions of the fruit called mace and nutmeg are sent into the market. The entire fruit is a species of *drupa*, of an ovoid form, of the size of a peach, and furrowed longitudinally. The nutmeg is the innermost kernel or seed, contained in a thin shell, which is surrounded by the mace; and this again is enclosed in a tough fleshy skin, which opening at the tip separates into two valves. The nutmeg tree yields three crops annually; one in April, which is the best; one in August; and one in December.

Good nutmegs should be dense, and feel heavy in the hand. When they have been perforated by worms, they feel light; and though the holes have been fraudulently stopped, the unsound ones may be easily detected by this criterion.

Nutmegs afford two oily products. 1. Butter of nutmeg, vulgarly called oil of mace, is obtained in the Moluccas, by expression, from the fresh nutmegs, to the amount of 50 per cent. of their weight. It is a reddish-yellow butter-like substance, interspersed with light and dark streaks, and possesses the agreeable smell and taste of the nutmeg, from the presence of a volatile oil. It consists of two fats; one reddish and soft, soluble in cold alcohol; another white and solid, soluble in hot alcohol. 2. The volatile oil is solid, or a *stereoptène*, and has been styled *myristicine*. (*Ure's Dict. of Arts, &c.*)

NUTS. (Lat. nux.) The fruit of different species of *Coryli* or hazels. The kernels have a mild farinaceous oily taste, agreeable to most palates; a kind of chocolate has been prepared from them, and they have sometimes been made into bread. The expressed oil of hazel nuts is little inferior to that of almonds. Besides those raised at home, nuts are imported from different parts of France, Portugal, and Spain, but chiefly from the latter. The Spanish nuts in highest estimation, though sold by the name of Barcelona nuts, are not shipped from thence, but from Tarragona, whence the annual average export is estimated at from 25,000 to 30,000 bags, 4 to the ton. The annual entries of nuts for home consumption amount to from 100,000 to 125,000 bushels; the duty of 2*s.* a bushel yielding from 10,000 to 12,000*l.* nett. (*Commercial Dict.*)

NU'TTALITE. A mineral associated with calcspar, from Bolton, in Massachusetts: it occurs in prismatic crystals, and appears, from Dr. Thomson's analysis, to be an alumino-silicate of lime, potash, and iron.

NUX. A kind of fruit, hard, dry, not splitting, and containing only one seed; it is also extended by some writers to any similar fruit, whether it contains one cell or more than one. *See* NUTS.

NUX VOMICA. (Lat.) The fruit of a species of strychnos growing in the East Indies. It produces the alkaloid salts, strychnia, and bruchia, and is a very virulent poison.

NY'CTALOPS. (Gr. νυξ, *night*, and οπτομαι, *I see.*) One who only sees distinctly in twilight, or the dusk of evening.

NYMPH, *Nympha*. (Gr. νυμφη, *a nymph.*) The Metabolian insects are so called when in the second stage of their metamorphosis, especially when they possess the power of locomotion. *See* PUPA.

NYMPHÆ'A, was the name given to some public baths at Rome consecrated to the nymphs, with whose statues they were adorned.

NYMPHA'CEA. In Zoology, a name given by Lamarck to a family of Bivalves.

NYMPHÆA'CEÆ. (*Nymphæa*, one of the genera.) In Botany, a natural order of plants, containing the water lilies of various parts of the world; they are Polypetalous Polyandrous Exogens, with the sides of the cells of the fruit covered with numerous seeds. Their stems burrow among the mud of the places where they grow, and have slightly astringent narcotic properties. The species are most valued for the beauty of their flowers, which, in *Victoria regia*, are the largest in nature, measuring as much as four feet in circumference.

NYMPHA'LIS. A genus of diurnal Lepidopterous insects, now the type of a family.

NYMPHI'PARA. (Gr. νυμφη, *a nymph;* pario, *I produce.*) A hybrid name applied by Reaumur to a family of Dipterous insects, and changed by Latreille into *Pupipara*. See that word.

NYMPHS. (Gr. νυμφαι.) Female beings, in Grecian Mythology, partaking of the nature of gods and men. They peopled all the regions of earth and water, and were variously designated according to the places of their abode. Thus, the Naiades inhabited the streams, the Oreiades the mountains, the Dryades the woods, the Hamadryades trees, with which they were born and died. They are represented as very beautiful; they constituted the attendants of various of the higher female divinities, especially Diana, and were also considered as having been the nurses of many of the gods, as Jupiter and Pan. *See* NAIADS, NEREIDS.

NYSTA'GMUS. (Gr. νυσταγμος.) A winking of the eyes, as observed in a drowsy person.

O.

O. A letter of the vowel series, which, if arranged according to the nature of the sound, occupies a position between *a* and *u*. It is susceptible of numerous interchanges, for which the reader is referred to the *Penny Cyclopædia*. The Greeks had two forms of this letter, ο (ομικρον, or little *o*), and ω (ομεγα, or large *o*); the former of which was equivalent to the short, and the latter to the long pronunciation of this letter in other countries. Among the Irish, the letter O prefixed to a name was originally considered as a mark of family dignity; it is now, however, we believe, considered to be merely equivalent to *Fitz* in England and *Mac* in Scotland, indicating *son*.

O. In Music, the O, circle, or double C, or semicircle, is a note which we call a semibreve, and the Italians *circolo;* used by them to mark what they call *tempo perfetto*, and what we call triple time.

OAK. (Germ. eiche.) The general name of a well-known hard-wooded forest tree, much cultivated for the purposes of timber, particularly in ship-building, and in other cases when much exposure to the weather is required. There are several varieties of this valuable tree; but the common English oak (*Quercus robur*) claims precedence of every other. The oak timber imported from America is very inferior to that of this country: the oak from the central parts of Europe is also inferior, especially in compactness and resistance of cleavage. The knotty oak of England, the "unwedgeable and gnarled oak," as Shakspeare called it, when cut down at a proper age (from 50 to 70 years), is the best timber known. Some timber is harder, some more difficult to rend, and some less capable of being broken across; but none contains all the three qualities in so great and equal proportions; and thus, for at once supporting a weight, resisting a strain, and not splintering by a cannon shot, the timber of the oak is superior to every other.

A fine oak is one of the most picturesque of trees: it conveys to the mind associations of strength and duration which are very impressive. The oak stands up against the blast, and does not take, like other trees, a twisted form from the action of the winds. Except the cedar of Lebanon, no tree is so remarkable for the stoutness of its limbs: they do not exactly spring from the trunk, but divide from it; and thus it is sometimes difficult to know

* *Annales du Muséum*, vol. vi. p. 82. The figure given is, generally speaking, good; but the tail is too hairy, and contradicts the description.

which is stem and which is branch. The twisted branches of the oak, too, add greatly to its beauty; and the horizontal direction of its boughs, spreading over a large surface, completes the idea of its sovereignty over all the trees of the forest.

The oak is raised from acorns, sown either where the oak is to stand, or in a nursery whence the young trees are transplanted.

The colour of oak wood is a fine brown, and is familiar to every one: it is of different shades; that inclined to red is the most inferior kind of wood. The larger transverse septa are in general very distinct, producing beautiful flowers when cut obliquely. Where the septa are small, and not very distinct, the wood is much the strongest. The texture is alternately compact and porous; the compact part of the annual ring being of the darkest colour, and in irregular dots, surrounded by open pores, producing beautiful dark veins in some kinds, particularly pollard oaks. Oak timber has a particular smell, and the taste is slightly astringent. It contains gallic acid, and is blackened by contact with iron when it is damp. The young wood of English oak is very tough, often cross-grained, and difficult to work. Foreign wood, and that of old trees, is more brittle and workable. Oak warps and twists much in drying; and, in seasoning, shrinks about $\frac{1}{32}$d of its width.

Oak of a good quality is more durable than any other wood that attains a like size. Vitruvius says it is of eternal duration when driven into the earth: it is extremely durable in water; and in a dry state it has been known to last nearly 1000 years. The more compact it is, and the smaller the pores are, the longer it will last; but the open, porous, and foxy-coloured oak, which grows in Lincolnshire and some other places, is not near so durable.

Besides the common British oak (*Quercus robur*), the sessile-fruited bay oak (*Quercus sessiliflora*) is pretty abundant in several parts of England, particularly in the north. The wood of this species is said by Tredgold to be darker, heavier, harder, and more elastic than the common oak; tough, and difficult to work; and very subject to warp and split in seasoning. Mr. Tredgold seems disposed to regard this species as superior to the common oak for ship-building. But other, and also very high authorities, are opposed to him on this point; and, on the whole, we should think that it is sufficiently well established that for all the great practical purposes to which oak timber is applied, and especially for ship-building, the wood of the common oak deserves to be preferred to every other species. A well-informed writer in the *Quarterly Review* has the following remarks on the point in question: —

"We may here notice a fact long known to botanists, but of which our planters and purveyors of timber appear to have had no suspicion, that there are two distinct species of oak in England — the *Quercus robur*, and the *Quercus sessiliflora;* the former of which affords a close-grained, firm, solid timber, rarely subject to rot; the other more loose and sappy, very liable to rot, and not half so durable. This difference was noted so early as the time of Ray; and Martyn in his *Flora-Rustica*, and Sir James Smith in his *Flora Britannica*, have added their testimonies to the fact. The second species is supposed to have been introduced some two or three years ago from the Continent, where the oaks are chiefly of this latter species, especially in the German forests, the timber of which is known to be very worthless. But what is of more importance to us is, that *de facto* the imposture abounds, and is propagated vigorously in the New Forest and other parts of Hampshire, in Norfolk and the northern counties, and about London; and there is but too much reason to believe that the numerous complaints that were heard about our ships being infected with what was called, improperly enough, *dry rot*, were owing to the introduction of this species of oak into the naval dockyards, where, we understand, the distinction was not even suspected. It may thus be discriminated from the true old English oak: — The acorn stalks of the *robur* are *long*, and its leaves *short;* whereas the *sessiliflora* has the acorn stalks *short*, and the leaves *long:* the acorns of the former grow singly, or seldom two on the same footstalk; those of the latter in clusters of two or three close to the stem of the branch. We believe the Russian ships of the Baltic that are not of larch or fir are built of this species of oak; but if this were not the case, their exposure on the stocks, without cover, to the heat of summer, which, though short, is excessive, and the rifts and chinks which fill up with ice and snow in the long winter, are enough to destroy the stoutest oak, and quite sufficient to account for heir short-lived duration."

OA'KUM. The yarns of which rope is composed when twisted into fibre. When mingled with pitch it is used for stopping leaks.

OA'NNES. In ancient Mythology, the most celebrated divinity of the Babylonians. He was represented as a sea monster, with human feet and hands; and was said to dwell in the abysses of the Red Sea, whence he was in the habit of issuing daily, and proceeding to Babylon, where he communicated instruction on religion, the science of government, and the useful arts. It has been generally supposed that Oannes was identical with the god Dagon,

> —— Sea monster, upward man,
> And downward fish;

and it is certain that the worship of marine animals constituted a leading feature in the religious observances of the Syrians and the adjacent nations. *See* DAGON.

OAR. In Nautical Affairs, a long piece of timber, flat at one end, and round or square at the other, by which a boat, barge, or galley, &c. is propelled through the water. The flat part dipped into the water is called the *blade;* the other end is the *loom*, which terminates in the handle. The fulcrum of the oar is the hole in the gunwale called the *rowlock*, or between two pins called *thole pins*, or one thole pin with a loose strap for confining the oar. There are various nautical phrases contingent upon this term, a few of which may not, perhaps, be out of place here. *To boat the oars* signifies to lay them in from rowing; *to feather the oar*, to hold the blade horizontally, so as not to catch wind; *to lie on the oars*, to suspend rowing for any interval; this is also the salute given to persons of distinction in passing; to *ship* and *unship the oars*, respectively to fix them and throw them out of the rowlocks.

OA'SIS. (Derived from the Coptic ouah, Arab. wâh.) The name given to those fertile spots, watered by springs and covered with verdure, which are scattered about the great sandy deserts of Africa. The most noted are situated in the Lybian desert. The oases of Egypt are nothing more than valleys or *depressions* of the lofty plain which forms the extensive table-land of Eastern Africa. They bear, in many respects, a similarity to a portion of the valley of Egypt, being surrounded by steep cliffs of limestone at some distance from the cultivated land, which vary in height in the different oases, those rising from the southern oases being the highest; neither do they present a continuation of cultivable soil, all of them being intersected by patches of desert. They no doubt owe their origin to the springs with which they abound, the decay of the vegetation thence arising having produced the soil with which they are now covered. Their fertility has been deservedly celebrated; but the glowing eulogiums of travellers on their surpassing beauty are probably in a great measure to be ascribed to the striking contrast they present to the deserts of burning sand with which they are surrounded. It may appear contradictory, considering the high opinion the ancients entertained of the fertility and beauty of the oases, that they should have selected them for places of banishment; but that such was the case, at least under the Romans, is certain. A law of the *Digest*, lib. 48. tit. 22., refers to this practice; and it has been supposed that the poet Juvenal was one of those who suffered a temporary banishment (*relegatio*) to the oases, though the evidence of this is by no means clear. (*Biographie Universelle*, art. *Juvenal.*) But the fact of their being selected as places of banishment is not in anywise inconsistent with the received opinions as to their salubrity and fertility. They were selected, not because of their being naturally noxious or disagreeable, but because of their being, as it were, out of the world, and from the extreme difficulty of escaping from them. The larger oases have some fine remnants of antiquity; the most celebrated of which is the temple of Jupiter Ammon, at Siwah. (See the *Geo. Dict.* art. "Egypt," and the authorities there referred to.) *See* DESERT.

OAST. The term applied to a kiln for drying hops, and which differs from a kiln for drying corn chiefly in being heated by a stove with flues, instead of an open fire, the smoke and heat of which passes up through the corn.

OAT FIELD. *See* OPEN FIELD LAND.

OAT GALLS. *See* GALL NUTS.

OATH, is defined by Paley "the calling on God to witness, *i. e.* take notice of what we say; and invoking his vengeance, or renouncing his favour, if what we say be false, or if what we promise be not performed." By the jurisprudence of nearly all known nations it has been admitted, in one form or another, as the solemn test of truth in judicial proceedings. Thus, as a general rule, all evidence in such proceedings must be given on oath by English law; and the having taken such oath subjects the witness to the penalties of perjury if his testimony be false. The only exceptions are, 1. In favour of Quakers, Moravians, and Separatists, whose "affirmation" is now admissible in all judicial proceedings, whether civil or criminal. The 1 & 2 Vic. c. 77. extends this privilege to persons who have been Quakers or Moravians, but have left those communities, retaining their objections. 2. Persons entitled to privilege of peerage give in their answers, in chancery, "upon their honour," instead of on oath; and corporations put in answers under the great seal. Oaths are administered publicly in court,

where the witness is about to give his evidence viva voce; and by competent authority, where the evidence is reduced into writing, the attestation of the witness being termed his "affidavit."

Any believer in a definite form of religion can be a witness, and the oath may be administered "according to such forms and ceremonies as he may declare to be binding." (1 & 2 Vic. c. 108.) But persons who cannot take an oath are incapable of being witnesses; such, therefore, as will not declare their belief in God, in a future state of rewards and punishments, and that perjury will be punished by the Deity, are excluded; as well as those who, from their years or ignorance, are incapable of comprehending the nature of an oath.

Oaths are still required by law on many occasions besides the giving evidence in judicial proceedings, and were formerly in a still greater number, until the 5 & 6 W. 4. c. 62., which substituted declarations in a great variety of cases, especially relating to the customs, excises, and post-office. Besides the Quakers and Moravians, several small sects of Christians profess conscientious objections to oaths, grounded on the express language of the scriptures. The church of England, in common with the Catholic church in all ages, and with most varieties of Christians, considers judicial oaths lawful, and declares them so by her 39th article. They have also been held mischievous or unnecessary by some philosophical writers, especially Bentham, in his *Rationale of Evidence*. The only answer to his reasoning appears to be, that however unreasonable the belief that the duty of truth is rendered more imperative by the formality of an oath, still, while such belief is a prevalent one, or while the imagination of witnesses in general is impressed by its solemnity, the convenience of retaining the practice overbalances the disadvantages.

OATS. *See* AVENA.

OBE'DIENCE, PASSIVE, in Politics, signifies the unqualified obedience which, according to some political philosophers, is due from subjects to the supreme power in the state; insomuch that not only its lawful, but its unlawful commands, may not be forcibly resisted without sin. The doctrine of passive obedience or non-resistance was strongly professed by the church of England in the time of King James I.; much commented on by writers, both for and against it, under Charles and James II.; and condemned at the Revolution. *See* NON-RESISTANCE, and DIVINE RIGHT.

O'BELISK. (Gr. ὀβελίσκος, dim. from ὀβελος, Lat. obelus, *a needle, or dart.*) A lofty quadrangular monolithic column, "diminishing upwards, with the sides gently inclined, but not so as to terminate in an apex at the top; neither is it truncated or cut off at the summit, but the sides are sloped off so as to form a flattish pyramidal figure, by which the whole is suitably finished off and brought to a point, without the upper part being so contracted as to appear insignificant." Egypt was, properly speaking, the land of obelisks; and they are unquestionably to be reckoned among the most ancient monuments of that extraordinary people. Much learning and ingenuity has been expended in endeavouring to ascertain their origin, and the purposes for which they were erected; but it does not appear that any satisfactory solution of the problem has hitherto been given. It has been frequently asserted that obelisks were originally erected in honour of the sun, of which they were said to be symbolical, and that they served the purposes of a gnome or sun-dial; but this opinion is now almost totally rejected, and it is generally believed that obelisks were nothing more than monumental structures, serving as ornaments to the open squares in which they were generally built, or intended to celebrate some important event and to perpetuate its remembrance. They were usually adorned with hieroglyphics; and we learn from the testimony of Diodorus and Strabo that the inscriptions with which they were charged declared the amount of gold and silver, the number of troops, and the quantity of ivory, perfumes, and corn which all the countries subject to Egypt were required to furnish. The two largest obelisks were erected by Sesostris in Heliopolis. They were formed of a single block of granite, and measured 180 feet in height. When Egypt became a Roman province, Augustus removed these obelisks to his own capital; and this practice found numerous imitators both in some of his successors to the imperial throne, and, at a much later period, in many of the Roman pontiffs from the 16th century down to the present times. Of these obelisks that of the Lateran, which is the largest now known, being 105 feet in height exclusive of the pedestal, and weighing 440 tons, was brought by Constantine from Heliopolis to Alexandria, and thence by Constantius his son to Rome, where it was erected in the Circus Maximus. The obelisk next in size to that of the Lateran was placed originally in the Vatican circus by Caligula, but it now stands in the piazza of St. Peter's; its entire height is 132 feet, including the pedestal, &c. The obelisks most generally known, at least in name, are the Luxor, which was removed to Paris in 1833; and the two monoliths called Cleopatra's Needles, of which one is standing, and the other on the ground; but these are smaller than those we have adverted to, the Luxor being 76 feet in height, and the Needle of Cleopatra which still stands being about 63 feet in height, exclusive of the pedestal, &c. A full consideration of the Egyptian obelisks would involve us in the discussion of several most important questions, on which our limits preclude us from entering. Of these perhaps the most extraordinary is the wonderful knowledge of mechanical power which the Egyptians evinced in erecting and removing such gigantic structures,—a feat which it would require the greatest skill and ingenuity of modern engineers, even in the present comparatively perfect state of mechanical science, to accomplish. (See the learned treatise of Zoega on Obelisks; see also *Sir G. Wilkinson's Egyptians*, vol. iii., *passim*, which contains some excellent illustrations of the different methods adopted by that people for removing their huge structures from place to place.)

O'BELUS. In Diplomatics, a mark so called from its resemblance to a needle (Gr. ὀβελος); usually thus — or thus ÷ in ancient MSS. It was used by Origen, in his *Hexapla*, to mark the passages where something is found in the Septuagint which is not in the Hebrew. The common use of the line — in modern writing is to mark the place of a break in the sense, where it is suspended, or where there is an ungrammatical transition; but a paragraph introduced where the sense is suspended is more properly marked by the sign of a parenthesis.

O'BERON. In Mediæval Mythology, the King of the Fairies. Wieland's beautiful poem, and Weber's romantic opera of this name, the *Midsummer Night's Dream*, and innumerable other poems and tales of which he is the hero, have made the name of Oberon so familiar that it will be unnecessary to do more in this place than to state the origin of the fable. The name Oberon first appears in the old French *fabliaux* of Huon of Bordeaux; it is identical with Auberon, or Alberon, the first syllable of which is nothing more than the old German word Alb, *elf* or *fairy*, which, in the Helden-Buch and other old German poems, is expressed variously by Alberich or Alban. (See *Grimm's Deutsche Mythologie*, p. 256.) He was represented as endowed with magic powers, and with the qualities of a good and upright monarch, rewarding those who practised truth and honesty, and punishing those who acted otherwise. His wife's name was Titania, or Mab, whose powers have been so beautifully depicted in *Romeo and Juliet*.

OBE'SITY. (Lat. obesus, *fat.*) Unhealthy fatness. The tendency to the formation of fat is often so excessive as to constitute a disease, and it occasionally prevails in particular habits, so as to cause a most unsightly bulk of body, and to be independent of diet. The celebrated Lambert, who exhibited himself some years ago, was a remarkable specimen of this disease. He died in the fortieth year of his age, and weighed, a little before his death, 739 pounds. There is an account, in the *Philosophical Transactions* for 1813, of a girl, only four years old, who weighed 256 pounds from accumulation of fat.

When obesity is limited to the abdomen, arising from excessive deposition of fat in the omentum, and producing what is called a pot belly, or where it is the result of indolence and indulgence in luxurious diet, a slow and prudent change from a full to a spare diet, and the judicious use of purgatives and of appropriate modes of exercise, have occasionally effected remarkable cures.

O'BIT. (Lat. obitus, *death.*) In the Roman Catholic liturgy, a service performed for the repose of a departed soul.

OBI'TUARY. (Lat. obitarium.) A register in which are enrolled the names of deceased persons for whom obits are to be performed, and the days of their funeral. It is also used for the book containing the foundation or institution of the several obits in a church or monastery. In the former sense it is synonymous with *necrology*, in the latter with *martyrology*.

OBJECT-GLASS (of a refracting telescope or microscope). The lens which first receives the rays of light coming directly from the object, and collects them into a focus, where they form an image which is viewed through the eye-glass.

The excellence of an object-glass depends on the distinctness of the image which it forms. On account of the unequal refrangibility of the rays of light, it is necessary, in order to procure a distinct image, to employ an achromatic combination of lenses, formed of substances having different dispersive powers, and of such figures that the aberration of the one may be corrected by that of the other. The substances chiefly used are crown-glass and flint-glass; the dispersive powers of which are respectively as 3 to 5. By combining a convex lens of crown-glass with a concave lens of flint-glass, having their focal distances in that proportion, an image would be formed free from colour, but it would not be free from aberration. The determination of the form of the compound lens which shall give the least possible aberration for parallel rays is a problem which admits of exact

calculation. The following are the dimensions found by Sir John Herschel for an object-glass of thirty inches focal length, of the form shown in the annexed figure, where A B is the convex lens of crown-glass on the outside towards the object, and C D the concave lens of flint-glass placed on the inside towards the eye: radius of the exterior surface *a* of the crown lens, 20·0364 inches; radius of the exterior surface *b* of the flint lens, 41·1687 inches; radii of the interior surfaces *c*, 10·1604 and 10·1613 inches. (*Encyc. Metr.*, art. "Light," § 471.) When the lenses have the forms here indicated, the focal lengths of each, separately, are in the direct ratio of their dispersive powers; and the two inside surfaces have so nearly the same curvature that they may be ground on the same tool, and united by a cement to prevent the loss of light at the two surfaces.

Such are the forms indicated by theory; but the practical difficulties of forming a good achromatic object-glass, for a telescope of large size, are so great that it often costs more than all the rest of the instrument. This, however, principally arises from the extreme difficulty of procuring disks of flint-glass, above a certain size, sufficiently free from veins and imperfections as to be fit for the purpose. No object-glasses of a larger size than seven inches diameter have been made of glass manufactured in this country; and, notwithstanding the success of Fraunhofer at Munich, and of Guinand in Switzerland, the procuring of flint-glass fit for object lenses of a larger size seems to be still, in a considerable degree, a matter of accident. Fraunhofer executed a telescope for the Russian observatory at Dorpat, having an object-glass of 9 inches diameter. Another was prepared by him for the king of Bavaria of 12 inches diameter. The object-glass of Sir James South's large telescope at the Campden Hill observatory is nearly 13 inches in diameter, and was executed in Paris of glass manufactured by Guinand.

In the fine telescopes formerly constructed by Dollond the object-glasses were composed of three lenses, the two exterior ones, A B and C D, being of crown-glass, and convex, and the interior, E F, of flint, and concave. This combination gives a more perfect correction of the spherical aberration; but the advantage is more than balanced by the greater complexity of their construction, the risk of imperfect centering, and the loss of light at the six surfaces. They have accordingly been disused.

Various attempts have been made to dispense with the concave flint lens, by the substitution of some other refractive substance. Dr. Blair found that the dispersion of crown-glass was corrected by a fluid lens, composed of a mixture of solutions of ammoniacal and mercurial salts. He succeeded in making object-glasses in his manner, which at first gave promise of answering well; but it soon appeared that they were not durable, the fluid undergoing some chemical change which entirely destroyed its virtue. Professor Barlow, of Woolwich, has also made numerous experiments on this subject. His correcting lens is formed of the liquid sulphuret of carbon, inclosed between two disks of glass, and a ring of the same material, the fluid being introduced at a high temperature. A telescope which he made on this principle had a single object lens of 7·8 inches, and the fluid lens was placed at the distance of 40 inches behind it. The performance of this telescope was, however, far inferior to an ordinary one of the same dimensions, with the common double achromatic object-glass. *See* Achromatism, Lens, Telescope.

O'BJECT, OBJECTIVE. In Philosophy, opposed to *subjective*. *See* Subject, Subjective.

O'BLATE. (Lat. oblatus, *offered*.) In Ecclesiastical Antiquities, 1. A person who, on embracing the monastic state, had made a donation of all his goods to the community. 2. One dedicated to a religious order by his parents from an early period of his life. 3. A layman residing as an inmate in a regular community, to which he had assigned his property either in perpetuity or for the period of his residence. 4. A layman who had made donation, not only of his property, but his person, as bondsman to a monastic community. In France the king possessed, in ancient times, a privilege of recommending a certain number of *oblati*, chiefly invalided soldiers, to monasteries, whom they were bound to maintain.

Oblate, in Geometry, signifies flattened at the poles. Thus, an *oblate* spheroid is a spheroid of the same form as that which is produced by the revolution of an ellipse about its shorter axis. Such is the figure of the earth. *See* Degree, Earth.

OBLA'TION (Lat. oblatio, *an offering*), means, properly, an offering presented to the church. This practice commenced at an early period in the history of the church, for originally the Christian priesthood had no other maintenance or allowance than the free gifts or oblations of the people. In the middle ages, oblations were of various kinds, and were known by different names, according to the purposes for which they were presented. (See Palmer, *Orig. Liturg.* ii. 67.)

OBLIGA'TION. (Lat. obligo, *I bind*.) In the most general sense, a duty imposed by law, to the fulfilment of which one party is bound towards another. Obligations, according to the civil law, are said to arise in four ways; out of contracts, quasi-contracts, delicts, or quasi-delicts. A principal obligation is that by which a debtor is bound to his creditor; an accessory obligation, that by which one is bound to another to satisfy the contract of a third party. The Roman jurisconsults divided obligations into natural, civil, and mixed, and also into civil and prætorian. An obligation, by the law of England, is a bond with penalty and condition; it may also be by statute or recognizance. He who enters into an obligation is styled obligor; he towards whom it is entered into, obligee.

OBLIGA'TO. (Ital.) In Music, a term applied to a movement or composition written for a particular instrument. It sometimes means that a movement is restrained by certain rules, to give particular expression to a passage, action, &c.

OBLI'QUE. (Lat. obliquus.) Not direct, deviating from the perpendicular. Thus, *oblique angle*, in Geometry, is an angle greater or less than a right angle. *Oblique circle*, in the Stereographic Projection, is any circle oblique to the line of projection. *Oblique planes*, in Dialling, are such as recline from the zenith. *Oblique projection*, in Mechanics, is where a body is projected in a line, making an oblique angle with the horizontal line. *Oblique sailing*, in Navigation, is that which includes the calculation of oblique-angled triangles. *Oblique sphere*, in Geography, is that in which the axis of the world is inclined to the horizon of the place.

OBLIQUE MOTION. In Music, that wherein one of the parts holds on a sound, whilst the other rises or falls on any note whatsoever.

OBLI'QUITY OF THE ECLIPTIC. In Astronomy, the inclination of the plane of the earth's equator to the plane of the eliptic, or the angle formed by those two planes, on which the phenomena of the seasons depend. *See* Ecliptic.

O'BLONG. In Elementary Geometry, a rectangle, or right-angled parallelogram, whose length is greater than its breadth. An *oblong spheroid* is generated by the revolution of an ellipse about its longer axis, and therefore elongated at the poles; hence the term is used in contradistinction to *oblate spheroid*, which denotes a spheroid flattened at the poles. The *oblong* spheroid is otherwise called the *prolate* spheroid.

O'BÖE. (Ital.) A musical wind instrument, sounded through a reed. It is shaped somewhat like a clarionet, being slender in the upper part, but spreading out conically at the bottom, and consists of three joints or pieces, besides the reed. Its compass is generally two octaves and a fifth, from C, below the treble clef, to G, the fourth line above the staff. The ancient name of oboe was *wayght*, which is still visible in the modern word *wait* (*see* Waits); and in this form the oboe was in use as far back as the reign of Edward III. It is only since the beginning of the present century that the Italian form of this word came into general use; previously to that period the French name, *hautbois*, was universally current.

O'BOLUS. (Gr. ὀβολος.) An Athenian silver coin of very small dimensions; being only equal in value to about $1\frac{1}{4}d.$ of our money, or less, according to some computations. Seven of them were equal to an Attic drachma.

OBRI'NE. The name of a military order, instituted in the 13th century by Conrad, duke of Mazovia in Poland; styled also the order of Jesus Christ. It was instituted to levy war against the Russians.

OBSCU'RANTS, OBSCURA'NTISM. A kind of philosophical nickname, commonly applied, in Germany, to those who endeavoured in their writings to oppose the progress of modern enlightenment (Aufklärung) and their doctrines. (See *Conv. Lex.*)

O'BSEQUIES (Lat. obsequium, *complaisance*), were solemnities performed at the burials of eminent persons. The term is now used for the funeral itself.

OBSE'RVANTS, otherwise RECOLLECTS. A branch of the Franciscan order. *See* Recollects.

OBSE'RVATORY. A place or building destined for the purpose of making astronomical or physical observations, and furnished with appropriate instruments.

Astronomical observatories appear to have been erected in very early times, the tower of Babel being supposed to have been an edifice of this kind; and the tomb of Osmandias is celebrated in the history of ancient Egypt as having had a similar destination. The Indians and Chinese have also traditions of observatories which existed in the remotest ages of their histories. In fact, as the observation of the relative positions of the celestial bodies requires instruments of some sort, and as instruments must have a locality, the existence of observatories must have been coeval with the first progress made in

practical astronomy. (See Bailly, *Histoire de l'Astronomie Ancienne.*)

According to Weidler, the first regular observatory in Europe was erected at Cassel, in 1561, by William, landgrave of Hesse. That of Tycho Brahe, in the island of Huen, was founded in 1576. From this time private observatories began to be multiplied; and some of them, as that of Hevelius at Dantzic, produced results which materially contributed to the progress of astronomy; but it was only in the following century that they came to be regarded, in the principal countries of Europe, as important and necessary public establishments. The royal observatory of Paris was built in 1667, that of Greenwich in 1675; the latter being professedly for the benefit of navigation.

The principal use of astronomical observatories is to contain the instruments by which the observations are made that are requisite for forming catalogues of the stars, and tables of the sun, moon, and planets. These observations requiring great precision can only be made with instruments of considerable size, firmly supported, and capable of being accurately placed and maintained in certain determinate positions. In the present state of astronomy, no observation can be regarded as useful for the purposes just named unless made with an instrument fixed in the meridian. The instruments, therefore, which must be considered as essentially necessary to an observatory are a transit instrument and sidereal clock, for the purpose of observing right ascensions; a circle, for observing polar distances; and a barometer and thermometer, for the purpose of ascertaining the state of the atmosphere, in order to determine the corrections to be applied for refraction. Furnished with this apparatus, the astronomer is in a condition to obtain all the data requisite for the formation of catalogues and tables, and for establishing or perfecting the theories of the celestial motions and physical astronomy. Another instrument, though of secondary importance, is also wanted for the observation of phenomena out of the meridian, as eclipses, occultations, comets, &c. The most convenient instrument for this purpose is the equatorial (see the term); and if the astronomer carries his views to the exploring of the sidereal spaces, to observe the forms of nebulæ, and watch the changes and motions of double and multiple stars, the equatorial must be furnished with a telescope of the largest kind; or a powerful reflecting telescope, suspended so as to have a free motion in azimuth, may be employed instead of it. In this department of astronomy all depends on the goodness of the telescope; the objects to be examined being, in fact, only limited by the power of seeing them. But as these researches have no immediate practical application, they are not considered as included among the purposes for which public observatories are established, and are therefore left to the zeal of individuals.

Public observatories are now established and maintained by the governments of almost every civilized country, and the means provided of publishing the observations, and rendering their results immediately available to the progress of astronomical science. The number of private observatories, particularly in this country, is very considerable; and several of them, in regard to the sumptuousness of their instruments, vie with, and even excel, the first and best appointed public institutions. The following is a list of the principal public observatories, with their latitudes and longitudes (in time) from that of Greenwich, as given in the *Nautical Almanac* for 1843: —

	Latitude.				Longitude.

OBSE'SSION. (Lat. obsideo, *I besiege.*) The state of a person vexed or besieged by an evil spirit. In the language of exorcists, demoniacal obsession differed from demoniacal possession: in the latter, the demon had possession of the patient internally; in the former, he attacks him from without. Thus, the state of Sara, the bride of Tobias, whose bridegrooms were killed by an evil spirit haunting her (Tob. iii. 8.), was one of obsession. Well-known marks of obsession were the being miraculously hoisted or elevated in the air, speaking languages of which the patient had no knowledge, aversion to the offices of religion, and so forth. *See* Possession, Demoniac; Exorcism.

OBSI'DIAN. So named, according to Pliny, from Obsidius, who first found it in Ethiopia. A glassy lava. Volcanic glass. It is of various colours, but usually black, and nearly opaque. In Mexico and Peru it is occasionally manufactured into cutting instruments, or cut into ringstones. It consists of silica and alumina, with a little potash and oxide of iron.

OBSI'DIONAL CROWN. (Lat. obsideo, *I besiege.*) In Roman Antiquities, a crown granted by the state to the general who raised the siege of a beleaguered place. It was formed of grass growing on the rampart. *Obsidional* coins, in Numismatics, are pieces struck in besieged places to supply the want of current money. They are of various base metals, and of different shapes. Some of the oldest known are those which were struck at the siege of Pavia, under Francis I.

O'BSOLETE. (Lat. obsoletus.) In Zoology, the term implies that a part, or a spot, or other character, is scarcely discoverable.

OBSTE'TRICS. (Lat. ars obstetricia, from obstare, *to stand so as to give assistance.*) The name frequently given to the science of midwifery.

OBTE'MPER. (Lat. obtempero, *I obey.*) In Scotch Law, to obey or comply with a judgment of a court.

OBTU'NDENTS. (Lat. obtundo.) Mucilaginous, oily and other bland medicines, supposed to sheathe parts from acrimony, and to blunt that of certain morbid secretions.

OBTURA'TOR MUSCLES. (Lat. obturare, *to close up.*) Certain muscles which fill up openings in bones.

O'BVERSE, or FACE. In Numismatics, the side of the coin which contains the principal symbol: usually, in the coins of monarchical states, ancient and modern, the face in profile of the sovereign: in some instances, the full or half-length figure. *See* Numismatics.

OCCA'SIONALISM, or the System of Occasional Causes. In Metaphysics, a name which has been given to certain theories of the Cartesian school of philosophers, especially Arnold Geulinx, of Antwerp, by which they accounted for the apparent action of the soul on the body; *e. g.* in the phenomena of voluntary motion. According to these theories (which were more or less clearly developed by different writers), the will was not the *cause* of the action of the body; but, whenever the will required a motion, God caused the body to move in the required direction. *See* Harmony, Pre-established.

OCCIDE'NTAL. (Lat. occidens, *setting.*) In Gem Sculpture, a term applied to those precious stones which possess an inferior degree of hardness and beauty.

OCCI'PITAL BONE. (Lat. occiput, *the hind head.*) The irregularly shaped bone which forms the posterior and inferior part of the skull.

OCCULTA'TIONS (Lat. occulto, *I conceal*), sometimes called Lunar Occultations, or Occultations of Stars by the Moon, are those phenomena in which a star or planet becomes hidden from our view by the intervening passage of the moon. By analogy, a total eclipse of the sun might be called an occultation of the sun by the moon.

As the motion of the moon in her orbit is from west to east, it is obvious that, when she is about to pass over a star, the first contact, or the immersion, must occur on her eastern limb; and the emersion, or re-appearance of the star, must take place on her western limb. It should, however, be observed, that some slight exceptions to this rule may be found where the moon has considerable motion in declination, and where the star is only grazed over by a small portion of the northern or southern limb. In these few exceptional cases, the disappearance and re-appearance of the star may both occur either on the eastern or the western side of the limb.

An occultation, like a solar eclipse, is presented only to a portion of the terrestrial globe. For suppose an observer to be stationed at the star, with the moon between him and the earth, and that he could perceive the moon's disc projected on that of the earth; then he would observe that the moon, in her passage over the earth, only covered a portion of the terrestrial disc, and it is evident that the phenomenon of the occultation of the star could only be presented to that portion of our globe.

The principles which enter into the calculation of occultations are just the same as for eclipses of the sun; the only difference consists in the star having neither motion, parallax, nor semidiameter, so that the moon's motion and parallax are to be employed in place of the relative motion and the relative parallax. For the mode

of conducting the calculation, it will therefore be sufficient to refer to the article ECLIPSES, page 381.; and to observe that the consideration may perhaps be simplified by giving to the star a motion contrary and equal to that of the moon, and then supposing the moon herself to be stationary.

In the case of a planet, it may be necessary to take into account its motion and parallax, and perhaps its semidiameter, if great nicety is to be observed.

For minute details, in reference to the calculation of eclipses and occultations in all their varieties, the reader will do well to consult the Appendix to the *Nautical Almanac* for the year 1836.

OCCU'LT SCIENCES. (Lat. occultus, *hid.*) A term applied to the imaginary sciences of the middle ages — magic, alchymy, astrology, especially the former.

O'CCUPANCY. In Law, the taking possession by any one of a thing of which there is no owner, and the right acquired by such taking possession. Anciently, when a man held land *pur auter vie* (for the life of another), and died before that other, as this estate could not descend to his heir, nor revert to the donor until the determination of the life upon it, it was considered to belong of right to the first who took possession of it for the remainder of the life, which was termed general occupancy. And, when the gift was to one *and his heirs* for the life of another, the heir was said to take as special occupant. By the Stat. of Frauds (29 C. 2. c. 3. sec. 12.) a man is enabled to devise lands held by him pur auter vie; and if no such devise be made, and there be no special occupant, it goes to his executors and administrators.

O'CEAN. (Gr. *ωκεανος.*) In Geography, the vast body of water which surrounds the continents, and is the receptacle of all their running waters. It is divided by geographers into five great basins; viz. the Pacific Ocean, (so called by reason of its comparative stillness), which separates Asia from America, and is the largest of all the basins; 2. the Atlantic Ocean, which has Europe and Africa on its eastern shore, and America on its western; 3. the Indian Ocean, which washes the south of Asia, and the south-eastern coast of Africa; 4. The Arctic Ocean, which surrounds the north pole; and 5. the Antarctic, which surrounds the south pole. Other smaller portions of the great connected body of water are called *seas*, of which the Mediterranean, the German, the Baltic, and Black seas, are the most considerable. The superficial extent of the several great basins is not known with any certainty, nor, indeed, can their limits be exactly defined. From the nearest estimation that can be made of the extent of the continents and principal islands, it is supposed that nearly three fourths of the whole surface of the globe are covered by water. The Pacific Ocean alone exceeds the whole surface of the dry land.

Depth of the Ocean. — If the superficial extent of the ocean cannot be easily ascertained, it will readily be supposed that its depth is a problem of much greater difficulty. The bottom appears, wherever it has been reached by the sounding line, to have similar inequalities to those of the surface of the land: hence the depth must be extremely various; and it might be supposed from analogy that the greatest depth of the ocean is at least equal to the height of the highest mountains above its surface. Lord Mulgrave found no bottom in the North Atlantic Ocean with a sounding line of 4680 feet; and Mr. Scoresby sounded to the depth of 7200 feet, without the lead touching the ground. These experiments are not altogether to be depended on for the determination of such great depths; for, the pressure becoming very great, the lead may be drawn out of the perpendicular direction by currents, of which it may encounter more than one, flowing in different directions. Over a great portion of the Atlantic and Pacific Oceans no bottom has been found. The depth of the ocean in general, and the form of the bed on which it rolls, cannot, therefore, be determined by experiment. The mathematical theory of the oscillations of fluids has, however, thrown some light on the subject. Laplace demonstrated that the difference which is indicated by observation between the height of two consecutive tides depends on the law of the depth of the sea, and that, but for the influence of accessory circumstances, it would disappear altogether if the depth were constant. It follows, therefore, that, since the difference between the consecutive tides is extremely small, the depth of the sea, taking in a large extent of ocean, must be nearly uniform; that is to say, there must be a certain mean depth from which the variations are not considerable. (*Méc. Céleste,* book xiii.)

Level of the Ocean.—Were it not for the disturbing actions of the sun and moon, and of the winds, the level of the ocean would be every where the same, and its surface would have the form determined by the attraction of the whole mass of the earth, combined with the centrifugal force belonging to its velocity of rotation; that is to say, the surface would be that of an oblate spheroid of revolution. This uniformity, however, can never be established. The tide at every instant is at different heights in different parts of the ocean; and therefore the form of the surface, within the limits of the rise and fall of the tides, is variable. But even if we neglect the alternate rise and fall of the water which constitutes the tides, and take the surface of the ocean at its mean height, it is found by accurate levelling that all its parts do not coincide with the surface of the same spheroid. Gulfs and inland seas, which communicate with the ocean by narrow openings, are affected according to their position with regard to the prevailing winds. The level of the Red Sea was found, by the French engineers in Egypt, to be 32½ feet higher than that of the Mediterranean, which is supposed to be a little lower than the ocean. Humboldt concluded, from observations made on the Isthmus of Panama, that the waters of the Gulf of Mexico are about 2 feet higher than those of the Pacific Ocean. The Baltic and Black seas rise in spring from the great quantity of river water poured into them, and are lowered in summer by the joint effects of a small supply and increased evaporation.

Colour of the Ocean. — The usual colour of the ocean is a bluish-green, of a darker tint at a distance from land, and clearer towards the shores. According to Mr. Scoresby, the hue of the Greenland sea varies from ultramarine blue to olive green, and from the purest transparency to great opacity. The surface of the Mediterranean, in its upper part, is said to have at times a purple tint. In the Gulf of Guinea the sea sometimes appears white; about the Maldive Islands black; and near California it has a reddish appearance. Various causes cooperate to produce this diversity of tint. The prevailing blue colour may be ascribed to the greater refrangibility of the blue rays of light, which, by reason of that property, pass in greatest abundance through the water. The other colours are ascribed to the existence of vast numbers of minute animalculæ; to marine vegetables at or near the surface; to the colour of the soil, the infusion of earthy substances; and very frequently the tint is modified by the aspect of the sky. The phosphorescent or shining appearance of the ocean, which is a common phenomenon, is also ascribed to animalculæ, and to semiputrescent matter diffused through the water.

Temperature of the Ocean. — Water being a slow conductor of heat, the temperature of the ocean is much more uniform than that of the atmosphere. At a certain distance from the equator, it follows, though not very closely, the mean temperature of the corresponding latitudes; the solar action being greatly modified by the existence of currents which convey the temperature of one region to another; so that at any place the temperature of the water depends in some measure on the direction of the currents. Within the tropics the mean temperature at the surface is about 80° of Fahrenheit, and generally ranges between 77° and 84°. At great depths the temperature is probably nearly the same under every latitude. In the torrid zone it is found to diminish with the depth; in the polar seas it increases with the depth; and about the latitude of 70° it is nearly constant at all depths. But the small number of observations which have yet been made on this subject do not indicate any uniform law, according to which the variation of temperature at different depths is regulated.

Saltness of the Ocean. — The ocean holds in solution a variety of saline matters, of which by far the most abundant is common salt, constituting in general about two thirds of the whole. The saltness of sea-water at particular places is influenced by temporary causes—storms, for example; as well as by the neighbourhood of large rivers, and permanent accumulations of ice. A series of experiments on this subject were made some years ago by the late Dr. Marcet; and the following are the general conclusions which he deduced from them: — 1. That the Southern Ocean contains more salt than the Northern Ocean, in the ratio of 1·02919 to 1·02757. 2. That the mean specific gravity of sea-water near the equator is 1·02777. 3. That there is no notable difference between sea-water under different meridians. 4. That there is no satisfactory evidence that the sea at great depths is more salt than at the surface. 5. That the sea in general contains more salt where it is deepest; and that its saltness is always diminished in the vicinity of large masses of ice. 6. That small inland seas, though communicating with the ocean, are much less salt than the ocean. 7. That the Mediterranean contains rather larger proportions of salt than the ocean. (*Phil. Trans.* 1819; *Prout's Bridgewater Treatise.*)

The peculiar bitter taste of sea-water does not appear to belong to it beyond a certain depth, and is ascribed to the vegetable and animal matter held in a state of decomposition near the surface. *See* TIDES.

OCE'ANUS. In Greek Mythology, the oldest of the Titans: according to some, the son of Ouranos and Gaia. His consort was Tethys, his daughters the Oceanides. In Homer, the word ocean merely designates the "river," or stream, which, according to his notion, encompassed the earth.

OCHLO'CRACY. (Gr. *οχλος, a crowd,* and *κρατειν, to govern.*) A word coined to express the condition of a state in which the populace have acquired an immediate illegal control over the government; and, by a figure

commonly used in the exaggeration of political speakers and writers, a government in which the power of the lower classes predominates, either for a time or permanently.

O'CHRE. (Gr. ὤχρα.) In Painting, a colour prepared from a species of earth. It is of various hues, as yellow, red, green, blue, and black. The colouring matter of ochre is almost always oxide of iron.

O'CHREA. (Lat. *a boot.*) A name applied to stipules that are membranous, and surround the stem like a vagina or sheath, cohering by their anterior margins, as in *Polygonum.*

OCHRE OF IRON. A hydrated oxide of iron.

O'CHROITE. A name given by Klaproth to an earth supposed to exist in the mineral since called cerite.

O'CREÆ. (Lat.), in Roman Antiquities, were a sort of military boots made of tin, and ornamented with gold and silver. They were equivalent to the κνημιδες of the Greeks, and the greaves of the English. *See* GREAVES.

OCTAE'DRITE. *See* OCTOEDRITE.

OCTAETE'RIS. (Gr. οκτω, *eight*, and ετος, *a year.*) A cycle or period of eight years, at the lapse of which three lunar months were added. This cycle was in use till Meton's invention of the golden number, or cycle of nineteen years.

O'CTAGON. (Gr. οκτω, and γωνια, *angle.*) In Geometry, a plane figure contained by eight sides, and consequently having eight angles. When the sides and angles are equal, it is a *regular* octagon. If a denote the side of a regular octagon, the area is $a^2 \times 2 \tan. 67\frac{1}{2}^{\circ} = a^2 \times 4{\cdot}828427$.

OCTAGON. In Fortification, a place which has eight sides or bastions.

OCTA'NDRIA. (Gr. οκτω, and ανηρ, *a male.*) In Botany, that class of plants which has eight stamens.

OCTANS. In Astronomy, *Octans Hadleianus* (Hadley's Octant) one of the constellations formed by Lacaille in the southern hemisphere. *See* CONSTELLATION.

O'CTANT. In Geometry, the eighth part of a circle. In astronomy, *octant* denotes a position or aspect; thus the moon is in her octants when she is in the positions intermediate between her syzygies and quarters, or at 45°, 135°, 225°, and 315° from her conjunction.

OCTA'NUS. A fever which returns every eighth day.

OCTASTY'LOS. (Gr. οκτω, *eight*, and στυλος, *a column.*) In Architecture, a temple or other building having eight columns in front.

O'CTAVE. (Lat. octavus.) In Music, an harmonical interval, containing five tones and two semitones, called, by the ancient authors, *diapason.*

OCTAVE, in Ecclesiastical Antiquities, signified the eighth day after a feast, the feast day itself included. Thus, the first Sunday after Easter is the octave of Easter, styled *octava infantium*, and by other names. The Circumcision (Jan. 1.) is the *octave natalis domini*, the octave of Christmas. The introduction of octaves is said to have been founded on and borrowed from the Jewish ritual. The *octave* of a feast is sometimes called the *Utas*, or "the Utas day:" thus, "Wrytyn at Norwich on the Utas day of Peter and Powll." (*Paston Letters*, vol. iii. p. 189.)

OCTA'VO. (Lat.) Usually contracted 8vo.; that which by a peculiar folding has eight leaves to a sheet.

OCTO'BER. (Lat. octo.) The eighth month of the old Roman year, which began with March. The commencement of the year was transferred by Numa Pompilius to the 1st of January, but the months retained their names. October is now the tenth month. *See* CALENDAR.

OCTOE'DRITE. A mineralogical name applied to the octoedral oxide of titanium.

OCTOHE'DRON. (Gr. οκτω, *eight*, and ἕδρον, *side.*) In Geometry, one of the five regular solids, or Platonic bodies, contained under eight equal and equilateral triangles. Let

A = the linear edge or side,
B = the whole surface,
C = the solid content,
R = radius of circumscribed sphere,
r = radius of inscribed sphere;

then,

$$A = r\sqrt{6} = R\sqrt{2} = \sqrt{(\tfrac{1}{6}B\sqrt{3})} = \sqrt[3]{(\tfrac{3}{2}C\sqrt{2})}$$
$$B = 12r^2\sqrt{3} = 4R^2\sqrt{3} = 2A^2\sqrt{3}$$
$$C = 4r^3\sqrt{3} = \tfrac{4}{3}R^3 = \tfrac{1}{3}A^3\sqrt{2}$$
$$R = r\sqrt{3} = \tfrac{1}{2}A\sqrt{2} = \tfrac{1}{2}\sqrt{B\sqrt{\tfrac{1}{3}}} = \sqrt[3]{\tfrac{3}{4}C}$$
$$r = \tfrac{1}{3}R\sqrt{3} = \tfrac{1}{6}A\sqrt{6} = \tfrac{1}{6}\sqrt{(B\sqrt{3})}.$$

O'CTOPODS, *Octopoda.* (Gr. οκτω, *eight*; πους, *a foot.*) The name of a tribe of Dibranchiate Cephalopods, including those which have only eight feet or cephalic tentacular appendages; also of a sub-order of Apterous insects, including those which have eight feet, as the Tracheary Arachnidans.

OCY'THOE. (Gr. ωκυς, *swift*, and θεω, *I run.*) The name applied by Rafinesque to a naked Cephalopod, supposed to be that which inhabits and constructs the argonaut shell.

O'DALISQUES, properly ODALIKS. (Turkish oda, *a chamber.*) Female slaves employed in domestic service about the persons of the wives, female relatives, &c. of the sultan.

ODD NUMBER. In Arithmetic, any number not divisible by 2 without remainder; the series of odd numbers is 1, 3, 5, 7, 9, &c.; and the algebraic form by which they are expressed is $2n + 1$. Every prime number, excepting 2, is an odd number. The differences of the successive terms of the series of square numbers produce the odd numbers.

ODE (Gr. ωδη, *a song*), among the Greeks and Romans, was a short lyric composition, usually intended to be sung, and accompanied by some musical instrument, generally the lyre; hence the expression lyric verse. In the modern sense of the word, the ode appears to be distinguished from the song by greater length and variety, and by not being necessarily adapted to music. It is distinguished also from the ballad, and other species of lyric poetry, by its being confined to the expression of sentiment, or of imaginative thought, on a given subject, not admitting of narrative, except incidentally. The odes of Pindar, Anacreon, and Horace, are, in fact, the models on which the modern notion of the ode is formed, and which have been imitated in similar compositions in modern times. Until the science of Greek metres was so accurately explored as it has recently been, the Pindaric ode was supposed to admit of an excessive irregularity in the length and measure of lines; and hence the Pindaric odes of the last and preceding century are constructed on a system of absolute licence in this respect. In point of fact, however, a scheme of perfect metrical regularity pervaded the Greek ode both in Pindar and in the dramatic choruses, in which a strophe, or succession of lines in varied metre, is exactly answered in the antistrophe or corresponding series. On the other hand, the Anacreontic ode consists of a number of lines of the same metrical length and arrangement. The Horatian ode, again, is generally constructed on a different system, of which we have only a few instances in Greek, in the Fragments of Alcæus and Sappho: it consists of an indefinite number of stanzas, precisely similar to each other, each forming a complete metrical whole. (*See* METRE.) The Dithyrambic ode (quod vide) was a bacchanalian song; and as, from the attributes of the divinity to which it was dedicated, it admitted great irregularity and licence, the name has been transferred in modern times to all odes partaking of a wild and impetuous character.

O'DERITE. A variety of black mica from Sweden is so called.

ODE'UM, or ODEON. (Gr. ωδη, *a song.*) In ancient Architecture, a building wherein the poets and musicians contended for the prizes, both in vocal and instrumental music. Pericles, who was the first person to erect one of these buildings at Athens, instituted it for the choragi of the different tribes to rehearse their performances; but these buildings in the end were used for far different purposes from those for which they were originally destined. An odeum was to be found in all the principal cities of antiquity. The word odeon has been preserved in most modern languages: thus, there is an odeon in Paris, appropriated to theatrical and other similar purposes; and in Munich there is a concert-room with this name.

O'DIN. A Scandinavian deity, who seems, like the Jupiter of the Greeks, to have formed the connecting link between the ancient and more recent systems of their mythology. The conqueror Odin appears to have been a chieftain who led the Asi (the Goths) from the confines of Asia to northern Europe. But, when deified by public adoration, the attributes of an earlier deity seem to have been transferred to him. Odin is the chief of the gods; by his wife Freya he has two chief sons, Thor and Balder: the death of the latter (for the Scandinavian gods are not all immortal) furnishes many legends to the northern mythology, and is known to English readers by Gray's translation, *The Descent of Odin.* (See this article in the *Conv. Lex.*, and in the *Encycl.* of Ersch and Gruber.) The more ancient Odin, among the Romans, was regarded as the representative of their god Mercury. *See* WUOTAN.

ODO'METER. (Gr. ὁδος, *a road*, and μετρον, *measure.*) An instrument attached to the wheel of a carriage by which the distance passed over is measured. *See* PERAMBULATOR.

ODONTA'LGIA. (Gr. οδους, *a tooth*, and αλγος, *pain.*) The toothache.

ODONTO'LOGY. (Gr. οδους, and λογος, *a discourse.*) The branch of anatomical science which treats of the teeth. *See* DENTES.

O'DORIN. One of the products of the redistillation of the volatile oil obtained by distilling bone; it has a very concentrated and diffusible empyreumatic odour, and is regarded by Unverdorben as a peculiar salifiable base.

O'DYSSEY. (Gr. Οδυσσεια.) An epic poem, attributed, in general, to Homer, but, according to some modern hypotheses, not by the hand of the author of the *Iliad.* The

subject of the poem is the return of Ulysses (Ὀδύσσευς) from Troy to his native island, Ithaca.

ŒCO'NOMY. (Gr. οἶκος, *a house*, and νέμω, *I distribute*.) In Architecture, the harmonious and skilful combination of the parts of a building, which renders them suitable to their several purposes, and tends to connect them conveniently with each other.

ŒCUME'NICAL. (Gr. οἰκουμένη, scil. γῆ, *the inhabited earth*: used in the New Testament.) In the Greek language applied to ecclesiastical matters in the sense of universal. Several patriarchs of Constantinople and Rome assumed the title of œcumenical (particularly John, A.D. 590, and Cyril, his successor), apparently in opposition to the pretensions of the bishop of Rome. Œcumenical councils are those to which prelates resorted from every part of Christendom under the jurisdiction of the Roman empire. (Palmer, *Church of Christ*, vol. ii. p. 150.) *See* COUNCIL.

Œ'CUS. (Lat.) In Ancient Architecture, an apartment adjoining a dining room.

ŒDE'MA. (Gr. οἰδάω, *I swell*.) A puffiness or swelling of parts, arising from water collecting in the cellular membranes.

Œ'DIPUS. A personage renowned in the early or mythological stage of Grecian history, the son of Laius and Jocasta. An oracle had warned Laius that he should be killed by his son: in consequence of which he caused the child to be exposed, with one of its feet pierced and fastened with a thong (his name was accordingly derived from the swelling of the foot). The slave entrusted with him carried the child to Polybus, king of Corinth, and deceived Laius with a false report. Œdipus, when grown up, slew, in ignorance, his father Laius; acquired the sovereignty of Thebes, after conquering the Sphynx, and married his mother Jocasta. On becoming acquainted with their fatal destiny, Jocasta killed herself, and Œdipus deprived himself of sight. Such is the outline of the story familiar to us by the noblest efforts of the Greek tragedians. The tale of Œdipus himself affords the subject of two tragedies of Sophocles: the first (*Œdipus Tyrannus*), the most perfect example of dramatic *skill* which antiquity has left us; the second (*Œdipus at Colonus*), perhaps the most beautiful of ancient dramatic *poems*. The fate of his offspring is portrayed in several of the remaining dramas of the three great tragedians. The miseries inflicted on Œdipus seem to us to be wholly undeserved, and of a kind that it is impossible to approve. He was a mere passive instrument in the hands of Fate or Destiny, and was not morally culpable for the death of his father or the marriage of his mother. The acts, in fact, were the acts of the gods, and not of Œdipus. In themselves they were bad; but as he was totally ignorant of and did not intend them, he is no more to be blamed than a dagger in the hand of an assassin is to be blamed for the murder. And hence there can be no real sympathy with the miseries inflicted on Œdipus, and still less with those entailed on his offspring, who are made to suffer without cause or reason of any kind.

ŒNA'NTHE CROCA'TA. In Botany, the name given to the hemlock dropwort, a poisonous plant, growing in Pembrokeshire. It is called by the inhabitants of the country *five-fingered root*, and has some reputation as a remedy in diseases of the skin.

Œ'NOMANCY. (Gr. οἶνος, *wine*, and μαντεία, *prophecy*.) A mode of divination among the Greeks, from the colour, sound, &c. of wine poured out in libations.

ŒNOTHIO'NIC ACID. (Gr. οἶνος, and θεῖον, *sulphur*.) The acid which is formed during the action of sulphuric acid upon alcohol. Sertuerner gave it the above name: it is the sulphovinic acid of Vogel and other chemical writers.

ŒSO'PHAGUS. (Obs. Gr. οἴειν, *to carry*, and φαγω, *I eat*.) The tube by which food is conveyed from the posterior part of the mouth, or *pharynx*, to the stomach. The gullet.

Œ'STRUS. (Gr. οἶστρος, *a gad-fly*.) The name of a genus of Dipterous insects, some of which lay their eggs in the skin of quadrupeds, which they pierce for that purpose; others near the nose, up which the larvæ creep to the frontal sinuses. The flies of an allied genus (*Gasterophilus*) attach their eggs to the hairs in situations where they can be licked off and swallowed; when, their vitality protecting them from the action of the gastric juice, they are hatched in the stomach, and the larvæ attach themselves to the inner membrane, forming what are called "bots" in the horse.

O'FFERINGS. Literally, gifts presented at the altar in token of acknowledgment of the divine goodness. Offerings constituted a large portion of the Jewish worship. They consisted chiefly of bread, salt, fruits, wine, and oil, and had different names according to the purposes for which they were employed. A distinction has often been made between offerings and sacrifices (*see* SACRIFICE); the former being said to refer only to the fruits of the earth, the latter to animals; but this can scarcely have been the case, for both the burnt and the sin offering required animals to be sacrificed. Among the Greeks, Romans, and other nations, the same practice prevailed of offering at their altars wheat, flour, and bread. In a modern sense, the term *offering* is applied to certain dues payable by custom to the church, as the Easter offerings, &c. This latter custom has obtained from the first period of Christianity, when those who officiated at the altar had no other maintenance or allowance than the free gifts or offerings (oblationes) of the people.

O'FFERTORY. The first part of the Mass, in which the priest prepares the elements for consecration. In the English communion service, it denotes the sentences which are delivered by the officiating priest while the people are making their oblations or offerings. (See Palmer, *Orig. Liturgicæ*.)

O'FFICE FOUND. In English Law, an inquiry executed by some officers of the crown, when certain events have occurred in consequence of which the crown becomes entitled to take possession of real or personal property. Such are the finding of treasure under certain circumstances, the intestacy of a bastard, &c. The verdict of a coroner's jury of "felo de se" is an instance of office found, on which the crown is entitled to take possession of the effects of the deceased.

O'FFICER, is used generally to signify any person in the enjoyment of a post or office, whether civil or military, under the crown. Under their different heads will be found a notice of the chief civil and military officers; to these the reader is referred.

OFFI'CIAL. In the Canon Law, the deputy or lieutenant of a bishop, abbot, &c., or an ecclesiastical judge appointed by them. The principal official of the bishop is his chancellor, whose jurisdiction is coextensive with the diocese. An *officialis foraneus* (styled in English law commissary) is appointed to part of a diocese when large. The court of the official is styled in the canon law his *officiality*.

O'FFICI'NAL. In Pharmacy, such medicines as are directed by the Pharmacopæia to be kept ready for use in the apothecaries' shops.

O'FFING. A Nautical term, denoting a part of the sea at a considerable distance from the shore where there is deep water.

O'FFSET. In Architecture, the superior surface left uncovered by the continuation upwards of a wall where the thickness diminishes, forming a ledge.

O'FFSETS, in Surveying, are short distances from the chain-line, usually measured with a rod, called an off-set staff, the most convenient length for which is 6 feet 7·2 inches, being equal to 10 links of the surveying chain. *See* SURVEYING.

OFFSETS. In Gardening, young radical bulbs when separated or taken off from the parent roots are so called. One of the chief methods of propagating plants is by offsets. *See* PROPAGATION OF PLANTS.

O'GEE. In Architecture, the same as *cyma reversa*: see that art., and MOULDING.

O'GHAMS. A peculiar kind of short-hand writing in use among the ancient Irish. It consisted of certain lines and marks which derived their power from their situation and position as they stood in relation to one horizontal principal line, over or under which they were placed, or through which they were drawn; the characters or marks, according to their position, standing in the place of vowels, consonants, diphthongs, &c. (See the elaborate article in *Rees's Cyclopædia*.)

O'GIVE. (Etym. uncertain.) In Architecture, the term used by the French for the pointed arch.

O'GRES. (Fr.) The well-known name of those imaginary monsters with which the nursery tales of England abound. They are usually represented as cannibals, of malignant dispositions, and as endowed with gigantic height and power. It is difficult to speak with certainty of the origin of these fabulous creations; but it is probable that the term ogre is derived from Oegir, one of the giants in the Scandinavian mythology (see *Grimm's Deutsche Mythologie*, p. 146.); though it has been alleged, with perhaps more probability, that it has been borrowed from the Ogurs, or Onogurs, a desperate and savage Asiatic horde, which overran part of Europe about the middle of the 5th century.

OGY'GIAN DELUGE. The name given to a great inundation mentioned in fabulous history, supposed to have taken place in the reign of Ogyges in Attica, whose death is fixed, in *Blair's Chronological Tables*, in the year 1764 before Christ. *See* DELUGE.

OIL GAS. The inflammable gases and vapours (chiefly *hydrocarbons*) which are obtained by passing fixed oils through red-hot tubes, and which may be used as *coal gas*, for the purposes of illumination; it yields a more brilliant light than the latter, but is too expensive to be generally adopted. The apparatus for the production of oil gas is described in the *Quarterly Journal*, vol. viii. A gallon of common whale oil yields from 90 to 100 cubical feet of gas; and an Argand burner, giving the light of six or seven wax candles, consumes from $1\frac{1}{2}$ to 2 cubical feet per hour; whereas, to produce the

same light, from 5 to 6 cubic feet of coal gas are required.

OIL OF BRICKS. A term applied by the old chemists to the empyreumatic oil obtained by subjecting a brick which has been soaked in oil to the process of distillation at a high temperature. This oil is used by lapidaries as a vehicle for the emery by which stones and gems are sawn or cut.

OIL OF VITRIOL. *See* SULPHURIC ACID.

OIL-PAINTING. Painting in which the medium for using the colours is oil. It is said to have been unknown to the ancients, and not used earlier than the 14th century; its invention being attributed to John Van Eyck, sometimes called John of Bruges. By him it was supposed to have been imparted to one Antonio da Messina, who first brought it to Venice. Giovanni Bellini, by a stratagem, got possession of the secret from him, and then made it publicly known. Oil-painting has the advantages, above all other modes, of affording great delicacy of execution, a union and insensible blending of the colours, and above all that of imparting great force to its effects. The various colours chiefly used in oil-painting are, white lead, Cremnitz white, chrome, king's yellow, Naples and patent yellow, the ochres, Dutch pink, terra da Sienna, yellow lake, vermilion, red lead, Indian and Venetian red, the several sorts of lake, brown pink, Vandyke brown, burnt and unburnt umber, ultramarine, Prussian and Antwerp blue, ivory black, blue black, asphaltum. The principal oils are those extracted from the poppy, nut, and linseed. With the latter driers are introduced.

OILS. (Germ. oehle.) The term oil is applied to two dissimilar and distinct organic products, which are usually called *fixed* oils and *volatile* oils. The fixed or fat oils are either of vegetable or animal origin; they are compounds of carbon, hydrogen, and oxygen; the relative proportions vary but little in the several species. The following analyses of olive and spermaceti oil may be assumed as types of the rest: —

	Olive Oil.	Spermaceti Oil.
Carbon - - -	772	780
Hydrogen - - -	133	118
Oxygen - - -	95	102
	1000	1000

The *fixed oils* abound in the fruit and seed of certain plants; they are lighter than water, unctuous, and insipid, or nearly so; some of these require a low temperature for their congelation, such as linseed oil; others, such as olive oil, concrete at a temperature higher than the freezing point of water; some are solid at common temperatures, such as cocoa-nut oil. Some of these oils when exposed to air absorb oxygen, and gradually harden, forming a kind of varnish; these are called *drying oils*, and are the basis of paints, such as linseed oil; others become rancid, as almond oil. All these oils, like the different kinds of fat, consist of two proximate principles, called *stearine* and *elaine:* the former is the fatty portion, which first concretes on cooling the oil, and from which the elaine, or oily portion, may be separated by pressure. These oils cannot be volatilized without decomposition. At a red heat they are resolved into volatile and gaseous products, among which carburetted hydrogen, in several of its forms, predominates; hence the use of these oils, when volatilized and burned by the aid of a wick, as sources of artificial light. The action of the alkali on the fat oils is highly important, as forming soap.

The *volatile oils* are generally obtained by distilling the vegetables which afford them with water; they fluctuate in density a little on either side of water: they are sparingly soluble in water, forming the perfumed or medicated waters, such as rose and peppermint water; they are mostly soluble in alcohol, forming essences. A few of them, such as oil of turpentine, of lemon peel, of copivi balsam, &c., are hydrocarbons, that is, consist of carbon and hydrogen only; the greater number, however, contain oxygen as one of their ultimate elements. They are chiefly used in medicine and in perfumery, and a few of them are extensively employed in the arts as vehicles for colours, and in the manufacture of varnishes; this is especially the case with oil of turpentine.

OI'SANITE. An ore of titanium, from the department of Oise.

OLD MAN OF THE MOUNTAIN. The chief of the band Assassins* who established themselves in the mountainous district of Kohistan in Persia, in the 11th century, was so called. *See* ASSASSINS.

OLD RED SANDSTONE. A series of rocks interposed between the mountain limestone and slates. (*See* GEOLOGY.) It is included in *Murchison's Devonian System of Rocks*.

OLD TE'STAMENT. The name given to that part of Scripture which contains the collected works of the inspired writers previously to the advent of our Saviour. The period of their being collected is unknown. Some of them were in existence before the Babylonish captivity (600 years B.C.); others were collected at a later period; and the collection as it at present stands was completed in the second century before Christ. The Jews divided the Old Testament into the Law, the Prophets, and other writings known by the name Hagiographa, of which the Psalms were at the head. The contents of the Old Testament may be conveniently divided into the Historical Books, of which there are 17; the Poetical, of which there are 5; and the Prophetical, of which there are 16, distinguished into the books of 4 greater and 12 minor prophets. The Historical Books include the Pentateuch, the Book of Joshua, Judges, Ruth, 2 Books of Samuel, 2 Books of Kings, 2 Books of Chronicles, the Book of Ezra, of Nehemiah, and of Esther; the Poetical Books include the Book of Job, the Psalms, the Proverbs, Ecclesiastes, and the Song of Solomon; and the Prophetical comprise (of the greater) Isaiah, Jeremiah, Ezekiel, and Daniel, and (of the minor) Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habakuk, Zephaniah, Haggai, Zachariah, and Malachi. *See* BIBLE, TESTAMENT, PROPHETS, PSALMS, &c.

OLEA'CEÆ. (Olea, one of the genera.) The natural order of plants which contains the olive tree and the ash; it consists of trees or shrubs inhabiting the temperate parts of the world, and distinguished from others by their flowers being monopetalous and diandrous, with a valvate æstivation. *See* OLIVE.

OLECRA'NON. (Gr. ωλενη, *the ulna*, and κρανον, *the head.*) The head of the ulna. The process of the ulna which forms the elbow.

OLE'FIANT GAS. This variety of carburetted hydrogen is obtained by heating a mixture of two measures of sulphuric acid and one of alcohol. It is of somewhat less specific gravity than atmospheric air, 100 cubic inches weighing 30·5 grains. It burns with a bright white flame, and produces during combustion such proportions of carbonic acid and water as show that 1 volume of the gas is constituted of 2 atoms or volumes of hydrogen and 2 atoms of carbon; hence the equivalent of olefiant gas is ($2\,h. + 12\,car.$) $= 14$. When 2 volumes of chlorine are mixed with 1 of olefiant gas, and inflamed, hydrochloric acid is formed, and the charcoal of the gas makes its appearance in the form of dense black soot. If the mixture, instead of being kindled, be left standing over water, it soon condenses into a liquid looking like oil (hence the term *olefiant gas*), which is a hydrochloride of carbon. It has an aromatic odour, not unlike that of oil of caraways.

O'LEIC ACID. The product resulting from the action of alkalies upon the *elaine*, or liquid part of oils and fats.

O'LEIN. *See* ELAIN.

O'LEON. A peculiar liquid obtained by the distillation of a mixture of oleic acid and lime.

O'LERON, LAWS OF. *See* MARITIME LAW.

OLFA'CTORY NERVES. (Lat. oleo, *I smell*, and facio, *I cause.*) The nerves of smell. The first pair of nerves. They arise from the part of the brain called the *corpora striata*, and, perforating the ethmoid bone, are distributed over the mucous membrane of the nose.

OLI'BANUM. A gum resin, imported from the Levant, in yellowish white and nearly opaque drops or tears; it has a bitterish flavour, and has been used in medicine. When burned it exhales rather an agreeable odour, and is sometimes called *frankincense*. It is either the produce of the *Juniperus lycia*, or of the *Boswellia serrata*.

O'LIGARCHY. (Gr. ὀλιγοι, *few*, and ἀρχειν, *to govern.*) A state in which the sovereign power is lodged in the hands of a small exclusive class is so called. It differs from aristocracy, in that the latter term appears to designate a government in which the whole of a particular class or interest, *e.g.* the noble, the wealthy, &c., share directly or indirectly in the management of public affairs; while, in an oligarchy, it is a party or section formed out of one of these classes which enjoys the advantages of government.

OLI'VA. (Lat. oliva, *an olive.*) A genus of Pectinibranchiate Gastropods, dismembered from the *Volutes* of Linnæus, and so called on account of the long and elliptical shape of the shell. The aperture is narrow, long, and notched opposite to the spire, which is short; the folds of the columella are numerous, and resemble striæ. The animal has a large foot, the anterior portion of which is marked off by an incision on each side. The horns or tentacula are slender, and the eyes are on the middle of their outer side. The proboscis and the breathing tube are tolerably long; there is no operculum. The species of *Oliva* rival the cowries in beauty.

* There are few words whose etymology has exercised, and at the same time baffled the ingenuity of the learned, more than this. Perhaps the following may not be very remote from the truth. Throughout all the East a preparation of hemp is universally used to exhilarate the spirits by a luxurious species of intoxication. This is known to the Orientals by the name of *haschish*, and those who are addicted to it are called *haschischin* and *haschaschin*; two expressions, as Dr. Sacy remarks, which explain why the Ismaelians have been called by the historians of the crusades at one time *Assissini*, and at another *Assassini*. So that, instead of "a secret murderer," *assassin* implies, in point of fact, "an habitual drunkard." (*Quart. Rev.* vol. 24.)

O'LIVE. (Lat. olea.) A genus of trees belonging to the Diandria Monagynia class of plants. The *Olea Europæa* has an upright stem, with numerous branches, grows to the height of twenty or thirty feet, and differs from most trees in yielding a fixed oil from the pericarp instead of from the seed. The olive tree has in all ages been held in peculiar estimation; and some authors have styled it a "mine upon earth." It was sacred to Minerva. Olive wreaths were used by the Greeks and Romans to crown the brows of victors; and it is still universally regarded as emblematic of peace. The olive flourishes only in warm and comparatively dry parts of the world, as the south of France and Spain; in Italy, Syria, and the north of Africa; and though it has been raised in the open air in this country, its fruit did not ripen. The fruit is a smooth oval plum, about three quarters of an inch in length, and half an inch in diameter; of a deep violet colour when ripe; whitish and fleshy within; bitter and nauseous, but replete with a bland oil. Olives intended for preservation are gathered before they are ripe. In pickling, the object is to remove and to preserve them green by impregnating them with a brine of aromatized sea salt; and for this purpose various methods are employed. But it is chiefly for the sake of its oil that the olive tree is cultivated. Olive oil is pale yellow; its density is ·910. When fresh, and of fine quality, it is almost tasteless, having only a very slight and agreeable nutty flavour. It is less apt than most other fixed oils to become viscid by exposure, and hence is preferred for greasing clock and watch-work. It is largely used as an article of food. It is the principal article of export from the kingdom of Naples. Of 2,791,057 gallons imported in 1830, 2,034,237 were from Italy, 639,468 from Spain, 52,004 from Malta, 21,467 from Turkey, 11,300 from the Ionian Islands, and about 30,000 (at second-hand) from Germany and the Netherlands. There is a duty of eight guineas a ton on olive oil. (See *Dict. of Commerce, &c.*)

O'LIVILE. A peculiar amylaceous or crystalline substance, obtained from the gum of the olive tree.

O'LIVINE. A variety of *chrysolite* containing oxide of iron, of an olive green colour. It is sometimes found associated with meteoric iron.

O'LLA PODRI'DA. (Span. *putrid mixture.*) The name given to a favourite dish of all classes in Spain; consisting of a mixture of all kinds of meat cut into small pieces, and stewed with various kinds of vegetables. The epithet *podrida* is applied to this dish, in consequence of the poorer classes being obliged to serve it up so often that the odour arising from long keeping is far from agreeable. The phrase *olla podrida* is often used metaphorically in England for any incongruous mélange.

OLY'MPIAD. (Gr. ὀλυμπιας.) In Chronology, a Grecian epoch of four years, being the interval between the celebration of the Olympic games.

The Olympic games, so famous in Grecian history, were said to have been instituted about 1354 years before the Christian era; but, having fallen into disuse, they were revived by Iphitus, king of Elis, 844 years B.C. About a hundred years later, the practice was introduced of designating the Olympic period by the name of the victor. The first who received the honour was Coræbus, and the commencement of the Olympiad of Coræbus forms the principal era of Grecian chronology. The games in which he was victor were celebrated about the time of the summer solstice, 776 years before the era of the incarnation, in the 3938th of the Julian period, and 23 years, according to the reckoning of Varro, before the foundation of Rome. Before the introduction of the Metonic cycle, the Olympic year began sometimes with the full moon which followed, sometimes with that which preceded the summer solstice. Subsequent to the introduction of that cycle, the year always commenced with the eleventh day of the moon which followed the solstice, and it is usually regarded as beginning on the first day of July. It is necessary to observe, in the comparison of dates, that as the Olympiads begin about the 1st of July, the first six months of a year of our era correspond to one Olympic year, and the second to another. The first year of the first Olympiad began 776 years and six months before our era; hence, in order to reduce the date by Olympiads to our era, the rule is this: — Multiply the number of the past Olympiad by four, and add the odd years; subtract the sum from 777, if before Christ, or subtract 776 from the sum, if after Christ: the remainder will be the year before Christ or after Christ, if the event happened in the first six months of the Olympic year, that is, between July and January; but if the event happened in the last six months of the Olympic year, or between January and July, the remainder in either case must be diminished by one. For example, — the foundation of Rome (according to Varro) was laid in the 3d year of the 6th Olympiad, and 10th month of that year; required the date? Here 5 complete periods are elapsed: therefore, $5 \times 4 + 3 = 23$; and $777 - 23 = 754$, which being diminished by one gives 753 B.C. for the date. The month corresponds to April.

The method of computing time by Olympiads did not come into use till after the death of Alexander; and first appears in the Parian Chronicle, which was engraved about sixty years after that event. The first historian who used it was Timæus Siculus, who wrote a few years later. About 200 years B.C. Eratosthenes of Alexandria digested a chronological table of the Olympiads.

OLY'MPIC GAMES. The greatest of the national festivals of Greece, celebrated once every four years at Olympia, or Pisa, in Elis, in honour of Olympian Jupiter. Their institution is variously attributed to Jupiter, Pelops, and Hercules; but it appears that they had fallen into disuse for some time, till they were revived by Iphitus, 776 B.C. From this period it is that the Olympiads are reckoned. Like the other public festivals, the Olympiau games might be attended by all who bore the Hellenic name; and such was their universal celebrity that spectators quaternially crowded to witness them, not only from all parts of Greece itself, but from every Grecian colony in Europe, Asia, and Africa. In these games, none were allowed to contend but those who could prove that they were freemen of genuine Hellenic origin, and unstained by crime or immorality. The superintendence of these games belonged sometimes to the Pisans, but for the most part to the Eleans, by whom the Pisans were destroyed. On one occasion, in the 104th Olympiad, the management was forcibly seized on by the Arcadians. The contests at these games consisted in the athletic exercises, and also in those of music and poetry. The orators were crowned with garlands of wild olive. (See *West's Pindar; Thirlwall's Greece*, vol. i. 384.; and the other authorities.) The place where these renowned games were celebrated is a plain, now called Anti-Lalla, opposite the little town of Lalla. They commenced a little after the summer solstice, on the 14th of the Attic month Hecatombæon.

O'MBRIA. (Gr. ὀμϐρος, *rain.*) A name formerly applied to certain fossil Echini, under the supposition of their having fallen from the clouds.

OMBRO'METER. (Gr. ὀμϐρος, *rain*, and μετρον, *measure.*) A name sometimes given to the rain-gauge. *See* RAIN-GAUGE.

O'MELET. A pancake or fritter made of eggs, common in Spain, France, and Germany.

O'MENS. Casual indications, from which men believe themselves enabled to conjecture or foretel future events. The essential characteristic of all omens is their happening by accident; and it is this which distinguishes them from all other modes of divination. This branch of superstition seems nearly as ancient as the world itself; and in none do we find such remarkable indications of sameness of origin. Many external circumstances appear to be received in almost all countries as ominous. One of the most remarkable instances of this coincidence is mentioned in a recent number of the *Edinburgh Review*. The omens in which the Thugs, or secret murderers of India, believe with peculiar devotion, are almost the very same which an ancient Roman would have observed with equal attention; especially the appearance of animals on the right or left hand. In classical antiquity, however, omens appear to have multiplied, and to have been the subjects of more curious superstition in later than in earlier ages. There are numberless omens in Homer; but they are generally of the simplest description: — thunder and lightning; the appearance of some sacred birds, especially, as some critics have observed, those which have the highest flight, and might be supposed to have arrived immediately from the throne of Jove himself. Omens, among the Greeks (and, we may add, among almost all nations in periods of ignorance, and among the vulgar of the present day), may be divided into three classes: those derived from natural occurrences, relating to inanimate objects, lightning, earthquakes, phosphoric appearances, &c.; those derived from animals, especially birds, the region of their appearance, their voices, &c.; and those which the individual drew from sudden sensations of his own. Sneezing, in most times and countries, has been a peculiarly ominous occurrence. The Romans, as is well known, carried the science of omens to a very profound depth: the flight of birds was the main element in *augury;* the omens afforded by the entrails of sacrificed animals, in the learning of *extispicium.* One remarkable variety between Greek and Roman divination has often been noticed: the right hand in the former generally denoted good luck, and the left the contrary. Among the Romans this rule was reversed, although their writers in later times often adopt the Greek mode of expression. *See* AUGURS.

OME'NTUM. (So called from Lat. omen, because the soothsayers prophesied from its inspection.) The membrane is formed of a duplicature of the peritoneum, and encloses more or less fat. It is attached to the stomach, and lies on the anterior surface of the intestines.

O'MNIBUS. (Lat. *for all.*) The name given to a peculiar kind of public carriage, too well known to require to be described, which takes a number of passengers at a cheap common rate. They were first introduced

into Paris in 1825, whence they were introduced into London in 1829; and they are now to be met with in almost every large town both of this country and the Continent.

O'MNIUM. In Finance, a term used at the Stock Exchange to express the aggregate value of the different stocks in which a loan is now usually funded. (See *Dictionary of Commerce.*)

O'MNIVORES. (Lat. omnis, *all*, and voro, *I eat.*) The name given by Temminck to an order of birds, including those Insessorial species which feed on both animal and vegetable substances; as the starling.

OMOHYOI'DEUS. A muscle which pulls the os hyoides obliquely downwards: it is sometimes called the coracohyoideus: it arises from the superior costa of the scapula, and is inserted into the base of the os hyoides.

OMPHALO'DIUM. (Gr. ομφαλος, *the navel.*) The centre of the hilum of a seed, through which the nourishing vessels pass from the placenta into the seminal integuments.

OMPHALO'TOMY. (Gr. ομφαλος, and τεμνω, *I cut.*) The division of the navel string.

ONAGRA'CEÆ. (*Onagra*, an old name for the genus *Ænothera.*) An extensive natural order of Polypetalous Exogenous plants, very common in gardens, where they are much valued for the beauty of their flowers. They are known by all the parts of their flowers being arranged in fours. The genera *Fuchsia*, *Œnothera*, and *Epilobium* are common illustrations of the order.

ONE'IROCRI'TICS, or ONEIROCRITICAL SCIENCE. (Gr. ονειρος, and κρινω, *I judge.*) The science of interpreting dreams: treated of by Artemidorus, Macrobius, and other classical writers; by Thomas Aquinas, and others of the schoolmen; and, among many other moderns, by Cardanus, and Maio, a Neapolitan philosopher. According to all these writers, the secret of oneirocritical science consists in the relation supposed to exist betwen the dream and the thing signified; but they are far from keeping to the relations of agreement and similitude, and they frequently have recourse to others of dissimilitude and contrariety.

ONEIRODY'NIA. (Gr. ὄνειρος, and οδυνη, *pain.*) Disturbed dreams, including the nightmare and somnambulism.

ONISCI'DÆ. The name of a family of Isopodous Crustaceans, of which the wood-louse (*Oniscus*) is the type.

O'NOMANCY, or ONO'MOMA'NCY. (Gr. ονομα, *a name*, and μαντεια, *prophecy.*) A species of divination from the letters of a person's name. Many fancies of this sort were current among the ancients; such as that names in which the numeral letters amounted to the highest sum were most lucky.

ONOMA'STICON. (Gr. ονομα.) A work containing words or names, with their explanation, arranged in alphabetical or other order; a dictionary, commonplace book, &c. The best known work under this title is the *Onom.* of Julius Pollux, in ten books, a valuable repertory of ancient philological learning.

ONOMATOPŒ'IA. (Gr. ὄνομα, *name;* ποιεω, *I make.*) Literally, the making or manufacture of names; a word expressing by its sound the thing represented. In most languages the cries of animals are thus expressed; and the line of Aristophanes,

Ὁ δ' ἠλίθιος ὥσπερ πρόβατον βῆ βῆ λέγων βαδίζει,

shows that the modern Greeks have not correctly retained the sound of the eta (which they pronounce like our *e*), as the sound imitated from nature would not be thus represented. Ennius imitated the sound of a trumpet by the word *taratantara;* and, to represent the croaking of frogs, Aristophanes used βρεκεκεκὲξ κοὰξ κοάξ. (*Frogs*, i. 209.) Greek and German are peculiarly rich in words of this description. M. Charles Nodier has published a dictionary of those in French. (*Dictionnaire des Onomatopées Françaises.*)

ONTO'LOGY. (Gr. τὸ ὄν, *being*, and λόγος, *discourse.*) The science of *being* in itself, or its ultimate grounds and conditions. *See* METAPHYSICS.

ONY'CHIA. (Gr. ονυξ, *the nail.*) A whitlow.

ONY'CHOTEUTHIS. (Gr. ονυξ, *a claw;* τευθος, *a calamary.*) The name of the genus of Calamaries, in which the suckers of the cephalic appendages are armed with a hook.

O'NYX. A regularly banded agate, much prized for cameos, especially where the colours are very distinct and opposed. Any stone exhibiting layers of two or more colours strongly contrasted is called an onyx.

O'NYX. In Surgery, an abscess of the cornea of the eye; so called from its resemblance to the stone termed an onyx.

O'OLITE. (Gr. ωον, *an egg*, and λιθος, *a stone.*) A granular variety of carbonate of lime, frequently called *roestone.* The frequency of the occurrence of this particular form of limestone in a great series of deposits, lying between the subcretaceous formations and the new red sandstone, has caused English geologists to give the whole series the name of oolitic. It is largely developed in England and France. *See* GEOLOGY.

OOZO'A. (Gr. ωον, *an egg*, ζωον, *animal.*) A name applied by Ficinus and Carus to a primary division of the animal kingdom, including those in which the nervous and sanguiferous systems are incompletely developed, and in which the organization resembles the simple condition of the ovum of the higher classes. This division corresponds to the *Acrita.*

OPA'CITY. (Lat. opacus, *dark.*) In Optics, that quality of bodies which renders them opaque, or incapable of transmitting light. According to the Newtonian theory of light, opacity in natural bodies arises from the multitude of reflections caused in their internal parts. Newton thought it probable that the molecules of opaque and coloured bodies are separated by minute pores, either entirely void, or filled with some subtle matter of a different density from the body. If light enters such a body, and experience proves that it does penetrate the surfaces of opaque bodies, it will be reflected on encountering a molecule; and, if the molecules are extremely minute (in comparison of those of transparent bodies), the number of reflections may become so great that no part of the light will again escape from the surface. On this hypothesis, Sir J. Herschel remarks, that unless we admit a cause of opacity in atoms different from that which causes it in their aggregates, the atoms cannot be otherwise than absolutely pellucid, since no reflections can take place where there are no intervals, and no change of medium. Of the sufficiency of this cause, either in natural bodies or atoms, there does appear, he adds, some room for doubt, as it seems difficult so to conceive their internal reflections that the rays subjected to them shall be *all* and *for ever* retained, entangled, as it were, and running their rounds from atom to atom, without a possibility of reaching the surface and escaping; which, were they to do, it is evident that every body so constituted receiving a beam of light would in fact only disperse it in all directions in the manner of a self-luminous one. (*Ency. Metr.*, art. "Light.")

O'PAL. A beautiful mineral characterized by its iridescent reflection of light: it is very brittle. It consists of silica, with about 10 *per cent.* of water. *Common opal* in some of its characters resembles the preceding; but it has no play of colours, and is abundant, the former being a very rare mineral. Opal is found in different parts of Europe, but particularly in Hungary; in the East Indies, &c. (For some curious details as to this stone, see *Plin. Hist. Nat.*, lib. 37. c. 6.)

OPALI'ZED WOOD. Wood petrified by silica, and acquiring a structure resembling common opal.

O'PEN FIELD LAND. Arable lands unenclosed by hedges or other fences, and in the occupation of different individuals, or under different crops. In former times, only those parts of a farm which lay around the farmyard were enclosed, while the more distant parts were open, and called open fields, or out fields.

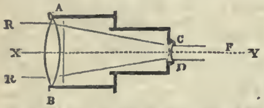
O'PENINGS. In Architecture, the piercings or unfilled parts in a wall, left for the purpose of admitting light, air, &c.

O'PERA. (Ital. *work.*) A musical drama, in which the music forms an essential part, and not merely an accompaniment. The whole dramatic art of the ancients possessed much of an operatic character. The choric parts were sung; and if the dialogue was not carried on in the musical tone termed *recitative* in modern times, it was certainly delivered in an artificially raised and sustained key, very different from the ordinary or oratorical speech. The first operas in modern times were performed in Italy, about the end of the 15th century. The *Orpheo* of Poliziano has been cited as the first complete piece of this sort. Jean Antoine Bäif introduced the opera into France, where the earliest representation of this kind is said to have taken place at the marriage of the Duc de Joyeuse, in 1582. In 1707, the opera of *Arsinöe*, consisting of English words adapted to Italian airs, was performed at Drury Lane, and a succession of entertainments of this kind terminated in the Italian opera. The first attempt at a wholly English opera was made by Sir William D'Avenant, in 1656. The opera is divided into *seria* and *buffa*, according to the subjects and the character of the music; and between the limits of both there is a third species, or *mezzo stilo*, not very accurately definable. The opera, properly speaking, admits only of singing and recitation, although, in some of the German operas, dialogue is also introduced. The romantic opera, which is considered as a German invention, is a compound between the two Italian species. Metastasio in Italy, and Goethe in Germany, have both written for the opera; but these are splendid exceptions, and the poetry has, in most instances, been held entirely subservient to the music. At the beginning of last century the opera, on its more general introduction into France and England, was attacked as an absurdity by almost all the wits and critics of the day. There were not, however, wanting defenders of this favourite child of the gay and fashionable world; and foremost among

them was Voltaire, to whose apology for the opera, in the preface to his tragedy of *Œdipe*, we take leave to refer the reader.

OPERA-GLASS. A small telescope used in theatres, whence it has its name.

The common opera-glass is nothing else than the Galilean telescope, invented by Galileo in 1609, which was the first ever employed for the purpose of exploring the heavens. A section of the instrument is represented in the annexed figure.



It consists of an object glass A B, the focal length of which is usually from 4 to 8 inches. The eye-glass, C D, is a double concave or plano-concave lens, from half an inch to 2 inches focus; the distance between the two lenses is equal to the difference of their focal lengths; and the magnifying power is in the ratio of those lengths. Rays of light, R R, falling on the object glass, are refracted towards the axis X Y, and proceed to meet in the focus of the lens at F. But before they reach that point they are intercepted by the concave lens C D, the focus of which is also at F, and by which they are restored to their parallelism. The rays, therefore, proceeding from the object enter the eye, which is applied to the lens C D, without crossing each other, or forming an image; and hence the distinctness of the Galilean exceeds that of all other telescopes; hence, also, there is no inversion of the image, and, as there are only two glasses, the loss of light is inconsiderable.

The lens A B may be either single or compound. If a single lens of plate-glass is used, it should be nearly convexo-plane; if a convex of plate and a concave of flint be combined to form the compound lens, the former should be nearly convexo-plane, and the latter concavo-plane. As to the eye-glass, it is always single; and the plano-concave form is perhaps better than the double concave, the eye being, in fact, never placed in actual contact with it. For any magnifying power above 3 or 4, it ought to be limited to an aperture rather less than that of the pupil of the eye; and where distinct vision is desired, the eye should be placed as accurately as possible on the axis of the instrument. (*Coddington's Optics*.)

The area or field of view of this instrument is very limited, and for this reason it cannot be used with any high magnifying power. *See* Telescope.

OPE'RCULUM. (Lat. operio, *I cover*.) The lid of any thing: applied by botanists to the cap of the pitcher of *Nepenthes*, to the loose apex of such fruits as that of *Lecythis*, to the conical limb of the calyx of *Eucalyptus*, and to the body which closes up the theca of a moss.

Operculum. In Zoology, this term is applied to the apparatus supported by four bones which protects the gills of fishes; also to the horny or calcareous plate which closes the aperture of univalve shells; and to the four calcareous pieces which defend the entrance to the tube of *Balanites* or bell-barnacles.

OPHICLEI'DE. (Gr. οφις, *a serpent*, and κλεις, *a key*.) The largest brass wind instrument used in the orchestra of the trumpet species, and forming the bass to that class of instruments: its compass is from double B *b* to A *b* above the line, in the bass clef, being three octaves.

OPHI'DIANS, *Ophidia*. (Gr. οφις, and ειδος, *form*.) The name of the order of reptiles which includes all the serpentiform species of that class, corresponding to the *Amphibia serpentes* of Linnæus.

O'PHIOMANCY. (Gr. οφις, and μαντεια, *prophecy*.) The art of divination from serpents. Thus the seven coils of the serpent seen on the tomb of Anchises were held to indicate the number of years of Æneas's future wanderings: —

Septem etenim gyros, septena volumina traxit.

O'PHITES. (Gr. οφις.) The name of an early sect of Christian heretics, who emanated from the Gnostics, so called from their worshipping the serpent that tempted Eve. They considered the serpent as the father of all the sciences, which, but for the temptation of our first parents, would never have been known. (Mosheim, *Eccl. Hist.*, vol. i.)

OPHIU'CHUS, or OPHIU'CUS; also called *Serpentarius*. One of the constellations of the northern hemisphere.

OPHTHA'LMIA, or OPHTHALMI'TIS. (Gr. οφθαλμος, *the eye*.) Inflammation of the eye. This term is applied to diseased action of various parts of the eye. In common cases its seat is the conjunctiva membrane, and it is relieved by fomentations of warm water or of decoction of poppy-heads, by leeches, cupping, purging; and, in violent cases, these depletive measures must sometimes be carried to a considerable extent, and aided by blisters to the temple or nape of the neck. Emetics have sometimes been of service. When all inflammatory symptoms have subsided, local astringents, and mild strengthening eye-waters, may be resorted to; but so long as any inflammation remains they should be most cautiously applied. Sometimes the iris is the seat of inflammation. This is attended with fever, great intolerance of light, and pain, and requires the same treatment. It sometimes terminates in a small abscess, which discharges its contents into the interior chamber of the eye, and the sight is destroyed by the permanent damage done to the part.

There is another form of ophthalmia in which the conjunctiva and inner membrane of the eyelids becomes inflamed and purulent, as in the *Egyptian ophthalmia*, which form of the disease is highly contagious. The swelling and purulent inflammation of the eyelids is so great as to close or distort them, and the ulceration sometimes extends over the cornea; the humours escape, the whole organ is frightfully disorganized, and the agony that attends the whole progress of the worst form of the malady is indescribable. The treatment originally resorted to consisted in bleeding and purging: the plan afterwards adopted was to give nauseating doses of tartar emetic, to remove the granulations by the scissors or knife, and afterwards to apply solutions of nitrate of silver or alum to prevent their reproduction.

There is a variety of ophthalmia called *metastatic*, caused by the translation of some other disease, such as gout, or by the application of some morbid poison to the part. Its treatment depends upon its origin.

The purulent opthalmia of new-born infants generally yields to the skilful application of mild astringent eye-waters, and to gentle aperients.

After the small-pox and measles, and some fevers, especially in scrofulous habits, the glands of the eyelids form a morbid secretion, which irritates and glues together the parts. This disease has been termed *psorophthalmia*; it frequently yields to fomentation with warm water, to a drop of vinous tincture of opium into the eye at bedtime, and to the application of the ointment of nitrate of mercury or red precipitate.

O'PIATE. (Gr. οπος, *juice*.) A medicine producing sleep. *See* Anodyne.

OPISTHO'GRAPHUM. (Gr. οπισθεν, *behind*, and γραφω, *I write*.) In Classical Antiquity, a set of tickets, or roll of parchment or paper, answering the purpose of a memorandum book or commonplace book, to enter notes and other extemporary matters to be revised afterwards; so called from being written over both on the front and back. Any ordinary MS. in which the transcriber had employed both the front and back of the papyrus was indeed an opisthograph, strictly so called; a practice to which allusion is made in the well-known verse of Juvenal: —

Scriptus et in tergo, nec dum finitus Orestes.

OPISTHO'TONOS. (Gr. οπισθεν, *backwards*, and τεινω, *I draw*.) A spasmodic action of the muscles, by which the body is bent backwards.

O'PIUM. (Gr. οπος, *juice*.) The inspissated juice of the poppy, obtained by wounding the unripe seed capsules of the *Papaver somniferum*, collecting the milky juice which exudes and dries in the sun, and kneading it into cakes. The cakes of the best opium are covered externally with pieces of dried leaves and the seed capsules of some species of *Rumex*. It should be of a rich brown colour, tough consistency, and smooth uniform texture; its peculiar narcotic smell should be strong and fresh; its taste bitter, warm, and somewhat acrid. The chemical analysis of opium has rendered it probable that its activity as a medicine depends upon the presence of a peculiar alkaline base called *morphia*, in combination with an acid which has been termed *meconic acid*. Opium also contains *narcotine*, *narceine*, *codein*, gum resin, extractive matter, and small portions of other proximate principles.

The chief countries in which opium is prepared are India, Egypt, Turkey, and other parts of Asia; it is even cultivated in Italy, France, and England, but the climate of Europe seems to be too uncertain to allow of its regular production. Opium is pretty extensively used, both as a masticatory and in smoking, in Turkey and India; but its great consumption is in China and the surrounding countries, where the habit of smoking it has become all but universal. The supplies for the Chinese market are derived from India and Turkey, but chiefly from the former. Indian opium is distinguished into three kinds: the Patna or that grown in the province of Bahar, the Benares, and the Malwa; of which the first is in the highest repute. The cultivation of opium in India is a strict government monopoly. Every one who chooses may, within the prescribed regulations, engage in the opium cultivation; but the drug, when prepared, must all be sold to the government at a fixed price, which is said to be so far from remunerating the growers that, were it not for the advances which government are obliged to make to enable them to carry on the business, the cultivation of opium would be discontinued,

in the greater portion of India. This monopoly has sometimes yielded a nett revenue of 1,000,000*l.* a year. This revenue has, however, of late years materially decreased, owing to the introduction into China of large supplies of opium from Turkey, into which it is found impossible to extend the monopoly. The East India opium is exported in chests of 159⅓ lbs. each. The introduction of opium into China was a legitimate branch of traffic down to the close of the last century. Ever since that period, however, the trade has been contraband; but though the Chinese government has issued edict upon edict prohibiting the importation of the drug, the consumption of Indian opium in China has, in little more than forty years, risen from 1000 to about 27,000 chests per annum. Such an extraordinary increase in a trade prohibited by law is attributable only to the corruption of the Chinese authorities. At first the trade was carried on at Whampoa, fifteen miles below Canton; and next at Macao, whence it was driven by the exactions of the Portuguese; and the principal entrepôt was, till the recent outbreak of hostilities between the British and Chinese, in the bay of Lintin. The opium is kept on board ships, commonly called receiving ships, of which there are often ten or twelve lying together at anchor. The sales are mostly effected by the English and American agents in Canton, who give orders for the delivery of the opium; which, on the order being produced, is handed over to the Chinese smuggler, who comes alongside at night to receive it. Frequently, however, the smuggler purchases the opium on his own account, paying for it on the spot in silver, it being a rule of the trade never violated that the money must be paid before the opium is delivered. When the drug is landed, the laws are equally set at defiance in its progress through the country, smoking houses being, it is said, every where established. During the first ten years of the present century, the exports from India to China were about 2,500 chests. In 1821-1822, after the introduction of Malwa opium into the markets of Bombay and Calcutta, the exports increased to 4,628 chests; and owing no doubt to the greatly increased supply and lower price of the article, the exports in 1831-1832 exceeded 20,000 chests, worth more than 13,000,000 dollars; and in 1837-1838 exceeded 30,000 chests, worth 20,000,000 dollars. In the beginning of 1839 the Chinese authorities resorted to decided measures to put a stop to opium smuggling; but the hostilities that consequently ensued between the two nations not having yet been composed, we shall not venture to enter upon so intricate a question, but shall merely observe, that whatever may be the result of the negotiations now pending, no system of restriction, how rigorous soever, will, in all probability, ever be able to check the smuggling of opium into China, where the popular tastes and habits are so decidedly in its favour. The opium consumed in England is derived chiefly from Turkey; but the supply is liable to great fluctuations. Thus, in 1830, the quantity imported from Turkey amounted to 192,136 lbs.; in the following year, to 8,184 lbs.; in 1833, to 72,020 lbs.; and in 1834, to 12,438 lbs. This remark is applicable to all the other places whence opium is imported into England, as well as to the quantity annually re-exported from England. Previously to 1828, the duty upon opium was 9*s.* per lb.; but in that year it was reduced to 4*s.*; and again in 1836 to 1*s.*, where it has since remained.

O'POBA'LSAM. (Gr. *οπος*, *juice*, and *βαλσαμον*, *balsam.*) Balsam or balm of Gilead. A compound of resin and essential oil of a peculiar fragrancy. It exudes from a species of *Amyris*.

OPODE'LDOC. A term invented and formerly applied by Paracelsus to a plaster for all external injuries; but in modern usage it signifies a liniment made by dissolving soap in alcohol, with the addition of camphor and volatile oils.

OPO'PONAX. A gum resin having a peculiar and rather disagreeable odour, formerly used in medicine. It is the produce of the *Pastinaca opoponax*.

OPO'SSUM. The common name of the Marsupial quadrupeds of the genus *Didelphis*, characterized by three kinds of teeth, viz. incisors, canines, and molars; by hinder hands, and a prehensile tail. With this organization the opossums, as might be expected, are arboreal in their habits; and feed on a mixed diet, in which animal food preponderates. The larger species have a well-developed abdominal pouch, in which the young are received at a singularly early stage of development. In some of the smaller opossums the characteristic pouch is nearly rudimentary, and the young are carried by the parent on the back, where they cling to the fur, and likewise hold on by entwining their little prehensile tails round that of the mother: the name *Didelphis dorsigera* is on this account given to one of the species. The true opossums are now limited to the American continent; but, during the Eocene period, there were species of *Didelphis* in both France and England.

OPPOSI'TION. (Lat. oppositio.) In a general sense, the fact of being in a state of contrary action or disagreement. In Politics, the name given in Great Britain to the party in parliament opposed to the administration for the time being, and which would most likely succeed to power were it displaced. A party in parliament which, though opposed to government, has no chance of succeeding to power were ministers dismissed, is not usually characterized by the term Opposition.

OPPOSITION, in Astronomy, denotes the aspect of two bodies when diametrically opposite to each other. Thus the moon, or a planet, is said to be in opposition with the sun when it passes the meridian at midnight.

OPPOSITION. In the Fine Arts, *contrast*; which see.

OPS. In Mythology, the Latin appellation of the Grecian goddess Rhea or Cybele; which see.

OPSIO'METER. (Gr. *ὄψις*, *sight*, and *μετρον*, *measure.*) An instrument for measuring the extent of the limits of distinct vision in different individuals, and consequently for determining the focal lengths of lenses necessary to correct imperfections of the eye. A contrivance for this purpose, by M. Lehot, is described in the *Annales des Sciences d'Observation* for June 1829, and in the Notes by M. Quetelet to the French translation of *Herschel's Treatise on Light*. Its principle depends on the appearance presented by a straight line placed very near the eye, in the direction of its axis; and the principle is carried into practice by placing a thread of white silk on a narrow rule covered with black velvet, and furnished with a suitable apparatus for marking the exact points at which the thread begins and ceases to be distinctly seen, when held in a certain position with respect to the eye. An instrument for the same purpose, on a different principle, had formerly been suggested by Dr. Young.

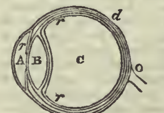
OPTATIVE MOOD. *See* GRAMMAR.

O'PTIC NERVES. The second pair of nerves. They arise from the *thalami nervorum opticorum*, and, perforating the bulb of the eye, form the *retina*.

O'PTICS. (Gr. *οπτομαι*, *I see.*) That branch of physical science which treats of light and vision.

The theory of light, and the different hypotheses respecting its propagation, having been explained under the term LIGHT, and its most remarkable properties being described under their respective heads (CHROMATICS, DIFFRACTION, INTERFERENCE, POLARIZATION, REFLEXION, REFRACTION, &c.), we shall here confine ourselves to the explanation of the phenomena and laws of vision, and the formation of images; and this, in fact, comprehends all that is meant by *Optics*, in the strict sense of the word.

Description of the Eye.—The human eye is of a spherical form, having a slight projection in front. The annexed figure represents a horizontal section of it through its axis. It consists of three principal chambers, filled with different *humours*, or transparent media of different refractive powers. The first of these media, occupying the anterior chamber A, is called the *aqueous* humour, and consists almost entirely of pure water. The cell in which the aqueous humour is contained is bounded on its anterior side by a strong horny transparent substance, called the *cornea*, the figure of which is an ellipsis of revolution about its major axis. The posterior side of the cell is formed by the *iris*, a kind of circular opaque screen, consisting of muscular fibres, by the contraction or expansion of which an aperture in its centre, called the *pupil*, is increased or diminished according to the illumination, in order to protect the eye and preserve its sensibility by equalizing the quantity of light admitted into it. The second humour, called the *crystalline lens*, B, enclosed in its capsule, lies immediately behind the pupil. Its figure is a solid of revolution, having its anterior surface much less curved than the posterior; and both surfaces are ellipsoids of revolution about their lesser axes. The crystalline is somewhat denser towards the centre than at the outside; the increase of density serving to correct the aberration, by shortening the focus of the rays near the centre. The third or *vitreous* humour, C, fills the posterior chamber of the eye. This fluid scarcely differs from the aqueous humour, either in specific gravity, or chemical composition, or refractive power.



The following are the refractive powers of the different humours of the eye, according to Sir David Brewster, the ray of light being incident on them from air: —

Aqueous Humour.	Crystalline Lens. Surface.	Centre.	Mean.	Vitreous Humour.
1·336	1·3767	1·3990	1·3879	1·3394

But as the rays refracted by the aqueous humour pass into the crystalline, and from the crystalline into the vitreous humour, the indices of refraction of the separating surfaces of these humours will be —

From aqueous humour to outer coat of crystalline 1·0466
From ditto to crystalline, using the mean index - 1·0353

From vitreous to crystalline outer coat - - 1·0445
From ditto to ditto, using the mean index - - 1·0332
(" Optics," *Cab. Cyclopædia.*)

The posterior surface of the cell of the vitreous humour is covered by the *retina*, *d*, a network of inconceivably delicate nerves, all branching from the *optic nerve*, O, which enters the eye obliquely at the inner side of the orbit, next the nose. The retina lines the whole of the cavity C from *r* to *r*, at which points the capsule of the crystalline commences. Its nerves are immersed in the *pigmentum nigrum*, a very black velvety matter which covers the choroid membrane, and the use of which is to absorb and stifle all the light which enters the eye as soon as it has done its office of exciting the retina ; thus preventing internal reflections, and consequent confusion of vision. The whole of these humours and membranes are contained in a thick tough coat, called the *sclerotica*, which unites with the cornea, and forms what is commonly called the *white of the eye*. The spot at which the optic nerve, O, enters the eye is totally insensible to the stimulus of light, and is therefore called the *punctum cæcum*. (Herschel on Light, *Ency. Metr.*)

From this description of the eye it is evident that light in passing through it must undergo a series of refractions, in the same manner as in passing through a system of lenses. When a pencil of luminous rays, proceeding from an exterior point, passes through the transparent cornea, and penetrates the aqueous humour, the divergence of the rays is diminished by this first refraction. The rays which pass through the pupil undergo a second refraction at the anterior surface of the crystalline, which renders them further convergent ; and, on leaving the crystalline and passing into the vitreous humour, they acquire their final degree of convergence, and proceed to form an image at a focus on the retina, or very near that membrane. Experience and calculation prove that when vision takes place with the least effort, the luminous point (or any very small object on which the eye is fixed) is at such a distance from the eye that the rays enter the eye with precisely that degree of divergence which is required, in order that after suffering the several refractions they may be brought to meet in a point on the retina itself. Hence it has been concluded that the sensation of sight is caused by the impression made by light on the retina, when it is concentrated on it in a single point or within a very small space.

The image of an object on the retina is evidently inverted with respect to the position of the object itself; for the ray proceeding from the upper extremity of an obobject, *a*, falls on the lower extremity *a'* of the image on the retina. Writers on optics have often puzzled themselves with attempts to explain the cause of erect vision from an inverted image ; the subject, however, is not worth the discussion which has been expended on it. " Erect," says Sir J. Herschel, " means nothing more than having the head farther from the ground, and the feet nearer than any other part. Now the earth, and the objects which stand on it, preserve the same relative situation in the picture on the retina that they do in nature. In that picture, it is true, men stand with their heads downwards, but then, at the same time, heavy bodies fall upwards ; and the mind, or its deputy the nerve, which is present in every part of the picture, judges only of the relations of its parts to one another. How these parts are related to external objects is known only by experience, and judged of at the instant only by habit."

Another circumstance, the cause of which has also been much discussed, is, that although an image of each object at which we look is formed on the retina of both eyes, the object appears single. Single vision with two eyes is attributed by Dr. Smith to the habit of referring the two impressions made on corresponding points of the two retinas to the same object ; and, in fact, if we press slightly on the cornea of one eye, so as to derange its optical axis, the two images, being no longer on parts of the retina which habitually correspond, will appear double. Those who have had one eye distorted by a blow see double, till habit has taught them anew to see single, though the distortion remains. (For a review of the various theories that have been proposed to account for this phenomenon, the reader may be referred to a paper on the Physiology of Vision, by Professor Wheatstone, in the *Phil. Trans.* for 1838.)

Straight lines drawn from the extremities of an object *a b* meet in a point *c*, nearly in the centre of the pupil, in the plane of the iris, which point is called the optical centre of the eye, and form the angle *a c b*, which is called the visual angle. On leaving the crystalline and entering the vitreous humour, the rays are slightly refracted, and form another angle, *a' c b'*, the base of which is the magnitude of the image on the retina. These two angles are not perfectly equal ; so that *a' b'*, the magnitude of the image on the retina, or the apparent magnitude, is not exactly proportional to the real magnitude, *a b*, for a given distance. But the difference is so small that it may in general be neglected, and then the visual angle becomes the measure of the apparent magnitude ; or the apparent magnitude of an object is proportional to its linear magnitude divided by its distance from the eye.

As the judgment which we form of the real magnitude of a distant object depends not only on the apparent magnitude, but also on our estimation of its distance, an erroneous estimate of the distance will necessarily produce an illusion with respect to the magnitude. Such illusions are frequent in the night time, when the darkness prevents us from distinguishing the real places of objects and their relative positions. An unusual increase or deficiency of the transparency of the atmosphere produces the same effect ; and at sea, where little assistance can be derived from the appearance of intervening objects, it requires a particular training of the eye to judge correctly of distances.

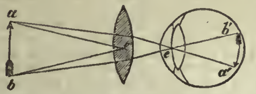
The effect of light on the eye has a sensible duration after the eye is shut, or the luminous object removed. During the twinkling of the eye, we never lose sight of the object on which we are looking ; and if a burning stick be attached to the extremity of a string, and whirled rapidly round, a complete circle of light appears. This *persistence* of light on the retina gives rise to a great number of illusions ; such as the apparent augmentation of volume of a musical chord when in rapid vibration, the train of light which appears to accompany falling meteors, &c. It was estimated by D'Arcy that the light of a live coal, whirled round at the distance of 165 feet, maintained its impression during the seventh part of a second. Experiments, however, of a more accurate kind, have shown that this time is not constant, but is influenced by several circumstances. Light must act on the eye for some continuance of time in order to produce a complete impression ; and it is found that the time during which the impression that has been produced can preserve an equal intensity after the action of light has ceased is greater in proportion as the impression is less intense. On the contrary, the whole duration of the impression is greater as the light is more intense. If the impression has been made by a strongly illuminated object, as the setting sun, it often passes through a series of different colours ; in other circumstances, it disappears, and is renewed after some seconds ; disappears again, and so on several times in succession.

The eye possesses considerable power of adjusting its parts so as to give distinct vision for all distances within certain limits. The first of these limits is the least distance from the eye at which small objects, as the print of a book, can be seen without effort ; and the second, the distance at which the image of the object becomes confused. The space between these limits is the field of vision ; but both its extent and distance from the eye vary considerably with respect to different individuals, and sometimes even with respect to the two eyes of the same individual. From the known dimensions of the eye, and the refractive powers of its different substances, it is found by calculation that the focal distances of two luminous points, situated at the two limits of the field of vision, differ by about one sixth part of the diameter of the eye.

All the refractions which take place in the interior of the eye are in the same direction ; consequently the eye, regarded as an optical instrument, is not achromatic. The absence of colour about the images formed on the retina, excepting in very particular cases, is to be ascribed in part to the small breadth of the pencil of luminous rays which passes through the pupil, but principally to the small focal distance of the eye ; in consequence of which the unequally refrangible rays can never be much separated from each other. It has also been surmised (*Coddington's Optics*) that a compensation takes place between the refractions at the cornea and the crystalline, a ray which is less refracted by the former being more refracted by the latter, in consequence of its passing through it at a greater distance from the axis.

Distinct vision depending on the convergence of the luminous rays which proceed from an object to a focus on the retina, it follows that if, from any defect in the original structure of the eye, or any deterioration of its form or powers, the rays which enter the pupil are not rendered sufficiently convergent to meet at the retina, or are rendered too much so, and thereby brought to a focus before they reach the retina, an imperfect and indistinct image will be produced. It happens with most persons, between the ages of thirty and fifty, that the crystalline lens begins to undergo a change, by which not only its form, but also its density and refractive power, are altered in such a manner as to leave it capable of affording distinct vision only of very remote objects. This defect is remedied by a convex lens, which makes up for the flatness of the crystalline, and renders parallel rays slightly convergent before entering the eye. Let *a b* be an object, *c* the lens, and *e* the centre of the eye, and suppose the object to be placed at the focal distance of the lens. Since the object is at the focus, the rays of a pencil diverging from any point *a* in it will emerge parallel to each other and

to $a\,c$; they will therefore, after refraction in the eye, be brought to converge on the retina at a point a', such that $e\,a'$ is parallel to $a\,c$. Similarly, rays from b, after refraction through the lens and the eye, will converge to the point b', such that $e\,b'$ is parallel to $b\,c$. Thus a distinct image $a'\,b'$ will be formed on the retina, and the apparent angular magnitude of the object seen through the lens will be the angle $a'\,e\,b'$, which is equal to $a\,c\,b$, the angle subtended by the object at the centre of the lens, and therefore greater than the angle subtended by the object at e, the centre of the eye. Hence the image appears enlarged; but, the nearer the lens is to the eye, the less will be the difference between the apparent magnitudes of the image as seen with and without the lens. When such lenses are employed in the form of spectacles, the enlargement of the image (which in this case is not intended) is hardly sensible, because the lens is commonly of low power, and because the person who must use it, to see distinctly, cannot easily make a comparison between the appearance of an object seen with or without the lens. The lenses of spectacles ought to be of the meniscus form (*see* LENS), in order to refract, without much indistinctness, pencils coming to the eye with any degree of obliquity. Such spectacles are called *periscopic*, and their advantage was first pointed out by Dr. Wollaston.



Sometimes the eye is so formed that its power of giving convergence is too great, and the rays are brought to a focus before they reach the retina. Persons having this defect are called *shortsighted*, from their inability to see distant objects distinctly. It arises from an increase of density in the central part of the crystalline; and its inconvenience is obviated by a concave lens, which increases the divergence of the rays before they enter the eye. For the same reason as mentioned above, the lens should be of the convexo-concave form, that is, convex on the outer side and concave on the inner side, the curvature of the latter being greater than that of the former. This lens diminishes the apparent magnitude of objects, but the effect is scarcely sensible. (*Smith's Optics;* Herschel's Treatise on Light, *Ency. Metropolitana;* Brewster's Optics, *Cabinet Cyclo.; Coddington's Optics;* Lamé, *Course de Physique.*) For optical instruments, see LENS, MICROSCOPE, TELESCOPE, &c.

OPTIMA'TES. (Lat.) A word sometimes used to denote the Roman nobility, in contradistinction to the plebeians, or populares.

O'PTIMISM. In Moral Philosophy and Theology, the system which regards physical and moral evil as elements of the universal order of things: so that every thing is good, viewed in relation to the whole; or, in the ordinary phrase, in which the doctrine is expressed, "all is for the best." This system was justified, with philosophical inductions, by Leibnitz, in his *Theodicæa* (which see), and is popularly illustrated by Pope, in his *Essay on Man;* but it is best known (as far as the name is concerned) by the irony of Voltaire, in his celebrated romance of *Candide.* The optimism of Leibnitz was based on the following trilemma: — If this world be not the best possible, God must either, 1. not have known how to make a better, 2. not have been able, 3. not have chosen. The first position contradicts his omniscience, the second his omnipotence, the third his benevolence. (See *Creuzer; Leibnitzii Doctrina de Mundo Optimo*, Lips. 1795.)

O'PTIMUS MAXIMUS. Epithets assigned to Jupiter by the ancient Romans to indicate his superlative greatness and goodness.

O'PTION. (Lat. opto, *I wish* or *choose.*) In Ecclesiastical Law, a prerogative of the archbishops of the church of England. Every bishop is bound, immediately after his confirmation, to make a legal conveyance to the archbishop of the next avoidance of any one benefice or dignity belonging to his see which the archbishop may choose (whence the name). If the archbishop die before the avoidance happens, the right of filling it up passes to his executors or administrators.

OPTION, at the Stock Exchange, signifies a per centage given for "the option" of putting or calling, *i. e.* selling or buying, stock in time bargains at a certain price.

OPU'NTIA. In Botany, the name given to those Cactaceous plants commonly called *Indian figs.* Their stems consist of flat joints, broader at the upper than at the lower end, becoming, however, eventually both continuous and cylindrical. Their native country is South America; but in some places the lava of Mount Etna is covered with them, and the large purple juicy fruits which they yield find considerable sale in the Sicilian markets. The cochineal insect (*Opuntia cochenillifera*) is fed on one of the varieties of *Opuntia.*

OR. (Fr. *gold.*) In Heraldry, one of the metals employed in blazonry. It is equivalent to topaz among precious stones, and Sol among planets. In engraving, it is represented by a surface sprinkled with equidistant dots.

ORA. An old Saxon coin, valued at sixteen pence, and sometimes, according to variation of the standard, at twenty pence. The word is of frequent occurrence in *Domesday Book*, and in the old records of the kingdom.

O'RACLE. (Lat. oraculum; from os, *a mouth.*) The name primarily given to the response delivered by the ancient heathen divinities to those who consulted them respecting the future, but afterwards applied both to the place where responses were given as well as to the divinities from whom the responses were supposed to proceed. To the desire so natural to man to obtain a glimpse into futurity, coupled with the ennobling belief that his destiny was predetermined in a higher sphere, is doubtless to be traced the origin of the art of divination, which has in all, but more especially in the earlier stages of society, exercised so powerful an influence over the human mind. But, of all the modes of divination, that by consulting the oracle was the most popular. In other cases, as the interpretation of events depended on man alone, there might be mistake or deception; but in the oracle, when the deity was believed to pronounce either in his own voice or in that of a consecrated agent, it was supposed there could be none. Hence oracles obtained such credit and celebrity in antiquity, but more especially among the Greeks, that they were resorted to on every occasion of doubt and emergency, both by princes and states, as well as by private individuals.

The general characteristics of oracles were ambiguity, obscurity, and convertibility; so that one answer would agree with several various and sometimes directly opposite events. Thus, when Crœsus was on the point of invading the Medes, he consulted the oracle of Delphi as to the success of the enterprise, and received for answer*, that by passing the river Halys he would ruin a great empire. But whether it was his own empire or that of his enemies that was destined to be ruined was not intimated; and, in either case, the oracle could not fail to be right. The answer of the oracle to Pyrrhus is another well-known instance of this sort of ambiguity, —

Aio, te, Æacida, Romanos vincere posse, —

as it might either be interpreted in favour of or against Pyrrhus. This ambiguity and equivocation was not, however, the worst feature that characterized the oracles of antiquity. They were at once ambiguous and venal. A rich or a powerful individual seldom found much difficulty in obtaining a response favourable to his projects, how unjust or objectionable soever. Such, for instance, were unquestionably the motives that dictated the favourable responses of the Pythia at Delphi to Philip of Macedon, which drew from Demosthenes the famous declaration, that the goddess *Philippised.* But such and so powerful is the influence of superstition, that this system of fraud and imposture maintained a lengthened ascendency, and the interested responses of the oracles frequently sufficed to excite bloody wars, and to spread desolation through extensive states.

The first oracles had their origin in the East, at a period to which the monuments of profane history do not ascend. The most ancient oracle is supposed to be that of Meroë; to which were afterwards added those of Thebes and Ammon, in all of which places the worship of Jupiter Ammon prevailed. From the Egyptians the use of oracles, along with a knowledge of many arts and sciences, passed to the Greeks, who soon surpassed every other nation both in the number and celebrity of their oracles. It has been affirmed that no fewer than three hundred oracles were established in different parts of Greece; but of those the oracles of Jupiter at Dodona, of Apollo at Delphi, and of Trophonius near Lebadeia (see these articles), may be mentioned as having enjoyed the highest reputation.† The oracles of antiquity had many leading features in common; but there were also several peculiarities about them, of which the variety of modes in which the oracular responses were delivered is one of the most striking. At Delphi responses were delivered by the Pythia, at Ammon by the priests, and at Dodona they issued from the hollow of an oak. Sometimes the response was communicated by letter; sometimes the desired information could only be obtained by casting lots; and sometimes the divinities chose to announce their will by dreams, visions, and preternatural voices.

Among the Jews there were several sorts of oracles: of these the Urim and Thummim (which see) bore a striking analogy to the heathen oracles; and the oracle of Bath-Kol, or *Daughter of the Voice* (mentioned in the *Talmud*, and other Jewish works), which originated after the time of Malachi, may be regarded as completely identical with them. The Old Testament teems with

* The Greek verse is,

Κροισος Αλυν διαβας μεγαλην αρχην καταλυσει.

Thus rendered in Latin,

Crœsus Halyn superans magnarum evertet opum vim

† It does not appear that the Romans ever had regularly established oracles among themselves; but on various important emergencies they had recourse to those of Greece, and especially to that of Delphi. (*Liv.* v. 15. &c.)

instances of the other species of oracles, in which supernatural revelations were made by means of dreams and visions; but every rational mind, even apart from scriptural authority, can at once perceive the wide distinction between the divine revelations vouchsafed in this manner to the Jews in ancient times, and the jugglery practised on the Gentile nations by the avarice and cunning of the priests. There are two points respecting oracles which have given rise to much controversy: viz. whether oracular responses ought to be ascribed to mere human ingenuity or to diabolical agency; and at what time responses ceased altogether to be given. With regard to the first point, most of the Christian fathers were of opinion that they ought to be attributed to diabolical machinations; but those who wish to see these arguments satisfactorily disposed of may consult, among others, the treatises of Ant. Van Dale, *De Oraculis Ethnicorum*, 1683, and of Fontenelle, *Histoire des Oracles*, 1689. With regard to the other question, at what time the oracles ceased to give responses, it has been frequently asserted that they became silent ever after the birth of Christ. Eusebius was the first who maintained this opinion; and many writers of great celebrity, anxious to do homage to the great Author of Christianity, have supported his views. In the *Hymn of the Nativity*, the most beautiful of his minor poems, Milton, in allusion to this theory, says—

> The oracles are dumb,
> No voice or hideous hum
> Rings through the arched roof in words deceiving.
> Apollo from his shrine
> Can no more divine,
> With hollow shriek the steep of Delphos leaving.
> No nightly trance or breathed spell
> Inspires the pale-eyed priest from the prophetic cell.

It appears, however, from the edicts of the emperors Theodosius, Gratian, and Valentinian, that oracles existed, and were occasionally at least consulted, down to A. D. 328. For several centuries previously they had been gradually sinking in public esteem, but at that period they entirely ceased; and there can be little doubt that this desirable consummation was mainly effected by the enlightening power of Christianity, and by the influence which even at so early a period it had acquired over a large portion of the then civilised world. (In addition to the works already quoted, see *M'Culloch's Geo. Dict.*, art. "Delphi;" Clavier, *Mem. sur les Oracles des Anciens*, 1819, &c.)

O'RAL, *Oralis*. (Lat. os, *a mouth*.) This term is applied to the various parts which form or relate to the mouth of animals.

ORA'NG, in the Malay language, signifies man; orang-utan is the man of the woods. It is by this term that we commonly designate the Indian or red orang. (*Simia satyrus*, Linn.) This species inhabits the great islands of Borneo and Sumatra, and attains the height of from four to five feet, measured in a straight line from the vertex to the heel. It has neither tail, cheek-pouches, nor ischial callosites; but has an appendix to the cœcum coli, as in man. It wants the ligament of the hip joint, and acquires an enormous laryngeal pouch when full-grown. *See* CHIMPANZEE.

O'RANGE. The well-known fruit of the orange tree, the *Citrus aurantium* of botanists. India and China are the native countries of the orange; and the Portuguese are entitled to the honour of having transferred the plant to other countries. The principal varieties of the orange tree are the orange, the lime, the lemon, and the citron, fruits which have now become so common as to give a tropical character to the dessert. The orange is not considered to have been grown in Europe till the 14th century; and in England they have been cultivated in conservatories since 1492. They are propagated either by seeds, by cuttings, by layers, by grafting, or by inoculation; but the plants grown from seeds require so long to come to perfection that they are seldom so propagated in England. Oranges are imported into this country in chests and boxes packed separately in paper. The best are brought from the Azores and Spain; but very good ones also come from Portugal, Italy, Malta, and other places. The orange trade carried on by this country is of considerable value and importance. Not only is the fruit held in high estimation, but, from the extreme productiveness of the tree, it is sold at a price little more and sometimes even less expensive than our ordinary domestic fruits. The entries for home consumption at an average of the three years ending 1838 amounted to about 260,000 boxes; each box containing about 700 lemons and oranges: the duty amounted to about 60,000*l*. a-year. The peel of the orange when preserved is a well-known article of confectionary; its flowers yield an essential oil scarcely less esteemed as a perfume than the celebrated ottar of roses; while, as if nature had intended every part of it for the use of man, the wood of the tree is susceptible of the highest polish, and is extensively employed in the arts.

O'RANGEMEN. The name given to the society instituted in Ireland in 1795 to uphold the Protestant religion and ascendency, and for the discouragement of Catholicism. It had office-bearers, a secret organization, distinctive or orange colours, and occasional processions. It was at length suppressed by act of parliament in 1836.

ORANGERY. A kind of gallery, in a garden or parterre, to preserve orange trees in during the winter season. For trees in large boxes a proportionably large and lofty house is requisite; it may be opaque on the north side, with a glass roof, front, and ends, of any convenient or desired length, width, and height. For one of moderate size, the height at the back wall may be fifteen feet, at front ten feet, and the width of the house fifteen feet. The floor may be either perfectly level, and the boxes placed on it, the largest behind, so as their tops may form a slope to the front glass, as in the conservatory of Prince Borghese at Rome; or if the trees are young, a stage may be erected for a few years, in order to raise the plants to the light: but if the trees are of a considerable size, the best way is to have square pits in the floor at regular distances, somewhat larger than each box, and in these to sink the boxes, covering them with mould, sand, or moss, nearly to the level of the pavement, so that each tree so placed and dressed will appear as if planted in a small compartment of earth. Such is the plan of the large conservatory in the royal gardens at Monza. The walk, unless where a stage is adopted, should be in the middle of the house, with corresponding doors in each end; but where the trees are young, and placed on a stage like greenhouse plants, the walk should be in front, as in no other situation could the eye of the spectator meet the foliage of the plants. Where the walk is in the middle, and a double row of trees on each side, as at Monza, the effect in winter is truly magnificent and gratifying.

Where the trees are to be planted as standards in the borders or floor of the house, it is essentially requisite to the health and beauty of the plants that the building be glazed on all sides. Showers might be supplied in Loddiges's manner; heat by steam, hot water, or flues; and in winter the beds might be covered with turf, strewed with daisies, violets, and primroses: these would come early into flower; and if the turf were kept very short about the roots of the flowering plants, and the trees in excellent condition, only those who have seen the first-rate regularly planted standard orange groves of Nervi could form an idea of the effect, which, by contrast with the external winter, would be felt as luxurious, and as anticipating real spring. An orangery is distinguished from a conservatory by its having an opaque roof, while that of the latter is glazed. The orangery at Versailles is the most magnificent that ever was built.

ORATO'RIO. (Ital., from Lat. oratorium, *a small chapel;* which again is derived from orare, *to pray*.) A sacred musical composition, consisting of airs, recitatives, duets, trios, choruses, &c., the subject of which is generally taken from scripture. The text is usually in a dramatic form, as in Handel's *Samson;* but it sometimes takes the form of a narrative, as in *Israel in Egypt;* occasionally it is of a mixed character, as in Haydn's *Creation;* and sometimes it consists merely of detached passages from scripture, as in the *Messiah*. The origin of oratorios has been variously ascribed; but the most prevalent opinion regards them as originally founded upon the spiritual songs and dialogues which were sung or recited by the priests of the oratory. (*See* ORATORY.) The more recent introduction of this species of musical drama is on all sides attributed to St. Philippo Neri, about the middle of the 16th century; but oratorios, properly so called, were not produced till about a century afterwards. At first the persons introduced were sometimes ideal, sometimes parabolical, and sometimes, as in the later oratorios, taken from sacred history; but this species of drama soon assumed a more regular form, and oratorios became great favourites in Italy, where they were constantly performed during the Carnival; and they have since given birth to some of the noblest and most elaborate compositions of the great masters both of that and other countries. Oratorios were first introduced into England by the great Handel in 1720, though they were not publicly performed till 1732; and such was their success that in 1737 they began to be performed twice a week during the season of Lent: a custom which, under the able management of T. C. Smith, Linley, and Arnold, &c., successively, was regularly continued down to a very recent period, when, in consequence of the introduction of profane music and other irregularities during the management of Mr. Ashley, they began to degenerate, and were at length discontinued.

Within the last two or three years similar performances, though not entitled *oratorios*, have been again revived at Exeter Hall by the *Sacred Harmonic Society*, on a scale of magnificence previously unknown.

O'RATORY, signifies, commonly, a room in a private house set apart for prayer. It differs from a chapel, inasmuch as it does not contain an altar, nor may mass be celebrated in it.

O'RATORY. *See* ELOQUENCE, RHETORIC.

O'RATORY, PRIESTS OF THE. Various congregations of ecclesiastical persons living in community, without being bound by any special vow, have assumed this title. The first congregation of the Oratory was founded by St. Philippo Neri, at Rome, in the beginning of the 16th century. Similar societies were soon formed in Italy and the Low Countries, but without any mutual connection. The congregation of the Oratory at Paris was founded by the cardinal Pierre de Bérulle in 1611, and had several houses in different parts of the country. It produced many men of celebrity; among others, Malebranche and Massillon. There can be no doubt that its chief object was to counterbalance the increasing influence of the Jesuits. (See *Mosheim's Eccl. Hist.* vol. iv.)

ORB (Lat. orbis), in the language of the old astronomers, usually signifies a hollow sphere; and they supposed the heavens to consist of such orbs or spheres, enclosing one another, and carrying with them in their revolutions the different planets. The *orbis maximus*, or great orb, was that in which the sun is placed. As the orbs were concentric, and their number equal to that of the known planets, with one for the moon and another for the fixed stars, it was neccessary to suppose them to be transparent or crystalline. Orb also denotes any round or circular body, and sometimes it is used synonymously with *orbit*.

ORBI'CULATES, *Orbiculata*. A tribe of Brachyurous Crustaceans, including those which have an oblong ovoid carapace.

ORBI'CULUS. In Botany, the whole mass of that part of a flower called the corona in the genus *Stapelia*; also, a round flat hymenium contained within the peridium of some genera of fungi.

ORBIT. (Lat. orbis, *a circle*.) In Astronomy, the path which any celestial body describes by its proper motion. The orbits of all the planets and satellites are ellipses; and recent discoveries seem to show that the orbits of double stars, which revolve about each other, are curves of the same kind. Some comets have been supposed to move in hyperbolic orbits. For the magnitudes and eccentricities of the planetary orbits, *see* PLANETS. *See* also MOON, SATELLITE, STAR.

ORBIT. In Ornithology, the term is applied to the skin which surrounds the eye: this is generally the base of feathers, for the facility of its movements, but especially so in the parrot tribe and the heron.

ORBIT. In Osteology, the bony cavity in which the eyeball is imbedded. Each orbit is formed by seven bones,— the frontal, maxillary, jugal, lachrymal, ethmoid, palatine, and sphenoid.

O'RCHARD. (Gr. ορχατος.) An enclosure devoted to the culture of fruit trees. The most productive orchards are generally such as are situated on declivities open to the south or south-east, and sheltered from the north, north-east, and west. The most suitable soil is a calcareous loam with a dry subsoil. The climate of orchards so situated is always warmer than any other kind of situation which this country affords, and the subsoil is more certain of being dry. The surface of the soil, in the case of orchards so situated, is generally kept under pasture; which, while it prevents the earth from being wasted away by rains, is favourable to the running of the roots immediately under the surface, by which they are sooner called into action by heat in spring, and sooner thrown into a torpid state by cold in autumn. The principal fruits grown in orchards of this description in Great Britain are the apple, the pear, the plum, and the cherry; and, wherever wheat can be ripened in the plains, these fruit will arrive at perfection on declivities such as we have mentioned.

O'RCHESTRA. (Gr. ὀρχήστρα, from ὀρχεῖσθαι, *to dance*.) In Architecture, that part in the interior of a theatre situate immediately between the stage and the place assigned to the audience. In the Greek and Roman theatres it was the part appropriated to the chorus and its evolutions, and was almost level with the stage. In the theatres of the moderns, it is the place appropriated to the musicians. The word is also applied to any erection for the performers in a concert.

ORCHIDA'CEÆ. (Orchis, one of the genera.) A natural order of Herbaceous Endogens, inhabiting all parts of the world excepting those climates situated upon the verge of the frozen zone, or remarkable for their exceeding dryness. They are well known for the singular form of their flowers. Some of them grow in the earth, others inhabit rocks and the branches of trees, and a few appear to be true parasites. They all belong to the class *Gynandria* of Linnæus; are often very agreeably scented; and sometimes produce an aromatic fleshy fruit, as in the case of vanilla, which contains a large quantity of benzoic acid. The nutritious substance called *salep* is prepared from the amylaceous roots of several terrestrial species.

ORCHIL. *See* ARCHIL.

O'RCIN. A crystallizable colouring matter or principle, obtained from a species of lichen (*Variolaria orcina*).

O'RDEAL. (In modern Latin ordalium; from the German urtheil, *judgment*.) The practice of referring litigated questions, and the guilt or innocence of parties under accusation to the judgment of God (testified, in popular belief, either by the event of lots, or by the success or failure of certain experiments), is of very ancient date; and was transferred, with other relics of their Pagan institutions, by the Teutonic nations, when settled in the provinces of ancient Rome, to their new bodies of jurisprudence. The ordeal was awarded in various cases; either arbitrarily by the court, or at the request of a party accused, who was anxious to clear himself; either as an alternative for trial by compurgation or by battle, or as the regular mode of deciding an issue. In the earlier ages of modern European history, the ordeal was under the peculiar protection of the clergy, who afterwards discountenanced it; and its gradual suppression must be mainly attributed to the decrees of popes and councils, of which several were pronounced against it in the course of the thirteenth century, beginning with the decree of the fourth Lateran council in 1215. Among the various forms of ordeal in use among different nations, the following are some of the most remarkable. The trial of the eucharist was used chiefly among the clergy; the accused party took the sacrament in attestation of his innocence, and it was believed that if he were guilty he would be immediately visited with punishment for the sacrilege. Of the same description was the corsnedd, or trial by the consecrated piece of bread or cheese, so much in use among the Anglo-Saxons. The trial of the cross was used, both in civil and criminal questions, in many European countries. See the supplementary formulæ to those of Marculfus, cited by Meyer, *Institutions Judiciaires*, liv. ii. c. 6. It appears that the litigants, or the accuser and accused, were to stand upright before a cross, and that he who fell or changed his position first was cast or condemned. This popular mode of ordeal was abolished by the capitulary of 816, in the reign of Louis le Debonnaire, as irreverent towards the mystery of the cross; but the abolition seems only to have been carried into effect in Italy and the provinces adjoining the seat of empire. The ordeal of hot water, in which the accused party plunged his hand into a vessel of boiling water, was used by the Salian Franks, when pagans, as early as the fifth century. It was afterwards extensively practised. In what was called the expurgatio simplex, the accused plunged his arm to the wrist; in the triple ordeal, to the elbow. Trials by burning iron were of various sorts: carrying a red-hot bar in the hand, and walking barefoot over heated ploughshares, mentioned in the imperial capitulary of 803, and adopted in England, as is well known from the celebrated example of Queen Emma. Among the Saxons, the iron was awarded to freemen, the water to those of inferior conditions. There can be no doubt that, in these severer forms of ordeal, some precaution was occasionally used by the clergy, under whose inspection and management the trial took place, to preserve parties whom it was wished to clear from suspicion from the ordinary consequences of such exposure. There were also ordeals by lot, as by the casual choice between a pair of dice, one marked with a cross and the other blank, mentioned in the laws of the Frisons. The famous trial of the bier, in which the supposed perpetrator was required to touch the body of a murdered person, and was pronounced guilty if the blood flowed, may be regarded as a species of ordeal, although founded more on usage than legal enactment; as this form of superstition did not become prevalent until later times, when ordeals were no longer a recognized part of the law. To the same head may be referred the various absurd and cruel methods which were adopted in different countries to try suspected witches. One of the most remarkable instances of the solemn application of the ordeal in later times took place in 1498, when the truth of the doctrines preached by Savonarola, a celebrated monk at Florence, was put to the test by a challenge between one of his disciples and a Franciscan friar to walk through a burning pile. This, however, may be rather regarded as the appeal of an enthusiast to the divine judgment than as an example of a recognized usage. Ordeals are of common use in the judicial practice of various heathen nations, especially of the Hindoos.

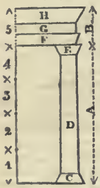
By the Anglo-Saxon laws, an option was given to the culprit in ordinary cases, when presented of a crime by the neighbourhood, or appealed against by the injured party, of defending himself by compurgation, or by the ordeal (of hot water or hot iron). If, being a villain, he could procure the testimony of his lord in favour of his character, the ordeal was simple; if otherwise, threefold. In the laws of William the Conqueror, we find that accusations between an Englishman and a Frenchman were decided, either by the Roman mode of trial by inquest, by battle, or by the ordeal. In general, it may be considered as Sir F. Palgrave remarks, rather as having afforded a last chance of escape to the accused party, than as an ordinary mode of deciding on guilt or innocence; since

it does not appear to have been resorted to in general, unless where the accused failed in clearing himself by the testimony of the neighbourhood to his character, or to the fact. Thus it stood in the same place as torture in the civil law, which, according to principle, was only applied where the evidence was sufficient to warrant a conviction, and the defendant refused to confess. When, however, the old form of trial by compurgation was abolished in England by the assizes of Hen. II., the trial by ordeal became more important than before. It appears that, in presentment by the inquest (whence originated the grand jury), the culprit was immediately adjudged, without option, to clear himself by ordeal; that, if he escaped this test, he was still condemned to abjure the country; so that the presentment became in some sort equivalent to a final trial. The *second* inquest or jury trial, at this period, is thought to have been only awarded as a matter of special favour. But when ordeal had been forbidden by the 18th canon of the fourth Lateran council, in 1215, as before mentioned, it was immediately disused in England; and hence, after a considerable interval, during which the practice of criminal law seems to have remained in a very uncertain state, the practice of trial by the second inquest, or petty jury, from being the exception gradually became the general rule. (See as to the early ordeals, *Mem. de l'Ac. des Inscr.* vol. xv.)

O'RDER. (Lat. ordo.) In the Fine Arts, the regular disposition of the parts of a work, so that neither confusion nor jarring effects may prevail.

Order. In Architecture, a system or assemblage of parts subject to certain uniform established proportions, regulated by the office each part has to perform. An order may be said to be the genus, whereof the species are Tuscan, Doric, Ionic, Corinthian, and Composite; and consists of two essential parts,— a column, A (see fig. 1.), and an entablature, B. These are subdivided: the first into three parts, namely, the base C, the shaft D, and the capital E; the second also into three parts,— namely, the architrave, or chief beam, F, which stands immediately on the column; the frieze G, which lies on the architrave; and the cornice H, which is the crowning or uppermost member of an order. In the subdivisions certain horizontal members are used, which, from the curved forms of their edges, are called mouldings. These are the ovolo, the talon, the cyma, the cavetto, the torus, the astragal, the scotia, and the fillet, which are defined under their several names in this work. The character of an order is displayed, not only in its column, but in its general forms and detail, whereof the column is, as it were, the regulator; the expression being of strength, grace, elegance, lightness, or richness. Though a building be without columns, it is, nevertheless, said to be of an order, if its details be regulated according to the method prescribed for such order.

(1.)

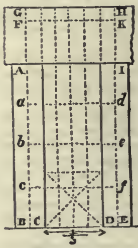


In setting up, or, as it is more technically expressed, in profiling an order, it is usual to make the entablature of the height of one fifth of the entire order. The height of the column is measured in terms of its lower diameter, which is divided into sixty parts, called minutes, used as a scale for the different subdivisions. In the Doric order the semidiameter of the column is called a module: it is, however, divided into thirty parts; so that there is, in fact, no essential difference between the scale of this and the other orders. The columns vary from seven to ten diameters in height in the different orders. The height of the entablature is usually divided into ten parts, whereof three are assigned to the architrave, three to the frieze, and four to the cornice; except in the Doric order, in which the height is divided into eight parts, whereof the architrave has only two, the frieze and cornice each three.

The rule above given for regulating the relative heights of the column and entablature is founded upon the practice of the ancients, who rarely exceeded or fell short of the proportion it establishes. Whether this practice of assigning one fifth of the height of the whole order to its entablature was arbitrary or empirical is worth an inquiry, which, we are inclined to think, has not been bestowed upon it in any architectural work, at least not in any one which has fallen under our notice: though the principles developed in a work by Le Brun, entitled, *Theorie de l'Architecture Grecque et Romaine, deduites de l'Analyse des Monumens Antiques* (fol. Paris, 1807), if carried through correctly, seems to point to the reason of the practice. One of the most obvious principles of proportion in respect of loads and supports, and one apparently founded on Nature herself, is, that a support should not be loaded with a greater mass than itself; or, in other words, that there should be an equality between the weights and supports; that is, in this case, between the entablature and column. In respect of the voids left between the columns or supports below the entablature, there seems to have been a great diversity of practice; for we find them varying from 1·03 to 2·18, unity being the measure of the supports. Le Brun makes the areas of the supports, weights, and voids equal to one another; and in the monumental specimens of the Doric order, such as the Parthenon, &c., he seems borne out in the law he endeavours to establish; but in lighter specimens, such as the temple of Bacchus, at Teos, where the supports are to the voids as 1 to 2·05, and in the temple of Minerva Polias, where the ratio is 1 : 2·18, he can hardly be considered correct. Indeed, there scarcely seems a necessity for such a limitation of the voids as he prescribes, seeing that, without relation separately to the weight and support, stability would be obtained so long as the centre of gravity of the load fell within the external face of the support. If, then, it be admitted that, as in the two examples above mentioned, the voids should be equal to the weights and supports jointly, we have the key to the rule; and, instead of being surprised at the apparently strange law of making the entablature one fourth of the height of the column, we shall find that none but the result assumed can flow from the investigation.

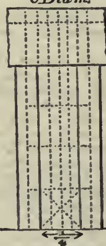
(2.)

6 *Diam.*



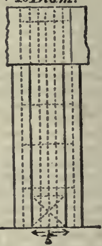
(3.)

8 *Diam.*



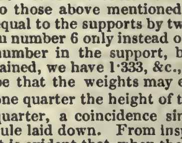
(4.)

10 *Diam.*



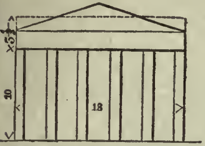
In the fig. 2., let AB be the height of the column, and let the distance between the columns be one third of the height of the column = C D. Now, if A B be subdivided into four equal parts, at *a*, *b*, and *c*, and the horizontal lines *a d*, *b e*, *c f*, be drawn; also, if C D be divided horizontally into four equal parts, and lines be drawn perpendicularly upwards intersecting the former ones; the void will be divided into 16 equal parallelograms, one half whereof are to be the measure of the two semi-supports. B C and D E being made equal then to one fourth of C D, it will be manifest, from inspection, that the two semi-supports will jointly be equal to 8 of the parallelograms above mentioned, or one half of the void. We have now to place the weight or entablature, A G H I, upon the supports or columns and equal to them in mass. Set up from A to F another row of parallelograms, each equal to those above mentioned, A F K I. These will not be equal to the supports by two whole parallelograms, being in number 6 only instead of 8: dividing, therefore, 8, the number in the support, by 6, the number already obtained, we have 1·333, &c., which is the height A G must be that the weights may equal the supports, exceeding one quarter the height of the column by only $\frac{33}{100}$ of such quarter, a coincidence singularly corroborative of the rule laid down. From inspection of figures 2., 3., and 4., it is evident that, when the void is $\frac{1}{3}$d of the height of the columns in width, the columns will be 6 diameters in height; when $\frac{1}{4}$th of their height, they will be 8 diameters high; and when $\frac{1}{5}$th of their height, they will be 10 diameters high; also, that the intercolumniation called systylos, or of two diameters, is constant by the arrangement. Let us now try the principle in another way: — Fig. 5. is the general form of a tetrastyle temple, wherein the columns are assumed at pleasure eight diameters high: then, $4 \times 8 = 32$, the area of the supports; and as, to fulfil the conditions, the three voids are to equal twice that area, or 64, they must in all be equal to 8 diameters, for $\frac{64}{8} = 8$; and the whole extent, therefore, will be 12 diameters of a column. To obtain the height of the entablature, so that its mass may equal that of the supports, as the measures are in diameters, we have only to divide 32, the columns, by 12, the whole extent of the façade, and we have two diameters and two thirds of a diameter for the height of the entablature; making it a little more than one quarter the height of the column, and again agreeing in terms of the diameter with many of the finest examples of antiquity, or very nearly so. If the pediment

(5.)



be employed, it is evident, the dotted lines A C, C B, being bisected in *a* and *b* respectively, that the triangles A E *a*, *b* B F, are equal to *a* D C and D C *b*, and the loading or weight will not be changed. Similar results are obtained in fig. 6., where the height is 10 diameters, the number of columns 6; the whole, therefore, 180, the supports being 60. Here $\frac{60}{18} = 3\frac{1}{3}$ diameters will be the height of the entablature.

(6.)



We cannot leave the subject without adverting to the rules given by Vitruvius (chap. ii. book iii.) — rules which were not his own only, but the result of the practice of the time in which he lived, and which, within small fractions, are most singularly corroborative of the assumed hypothesis of making the voids equal to twice the supports. Speaking of the five species of temples, after naming the different intercolumniations, and recommending the eustylos as the most beautiful, he thus directs the formation of temples with that interval between the columns. The rule for designing them is as follows:— "The extent of the front being given, it is, if tetrastylos, to be divided into eleven parts and a half, not including the projections of the base and plinth at each end; if hexastylos, into eighteen parts; if octastylos, into twenty-four parts and a half. One of either of these parts, according to the case, whether tetrastylos, hexastylos, or octastylos, will be a measure equal to the diameter of one of the columns. The heights of the columns will be eight parts and a half. Thus, the intercolumniations and the heights of the columns will have proper proportions." Further on in the same chapter he gives directions on aræostyle, diastyle, and systyle temples, on which it is unnecessary here further to enlarge. Let the above rules be examined. The tetrastylos is $11\frac{1}{2}$ parts wide, and $8\frac{1}{2}$ high: the area, therefore, of its whole front will be $11\frac{1}{2} \times 8\frac{1}{2} = 97\frac{3}{4}$. The four columns will be $4 \times 8\frac{1}{2} = 34$, or a very little more than one third of the whole area; the remaining two thirds, speaking in round numbers, being given to the intercolumns or voids. The hexastylos is eighteen parts long, and eight and a half high: the whole area, therefore, is $18 \times 8\frac{1}{2} = 153$. The six columns will be $6 \times 8\frac{1}{2} = 51$, or exactly one third of the whole area; the voids or intercolumns occupying the remaining two thirds. The octastylos is $24\frac{1}{2}$ parts in extent, and $8\frac{1}{2}$ in height: $24\frac{1}{2} \times 8\frac{1}{2} = 208\frac{1}{4}$. The eight columns will be $8 \times 8\frac{1}{2} = 68$, or very little less than one third of the area, and the voids or intercolumns about double, being the remaining two thirds.

The average of the intercolumniations in the first case will be $\frac{11\frac{1}{2} - 4}{3} = 2\frac{1}{2}$ diameters.

In the second case $\frac{18 - 6}{5} = 2\frac{2}{5}$.

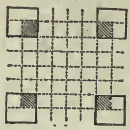
In the third case $\frac{24\frac{1}{2} - 8}{7} = 2\frac{357}{1000}$.

As, in our opinion, a discrepance between practice and theory will not shake the principle, we are not fearful of candidly submitting a synoptical view of some of the most celebrated examples of antiquity in which a comparison is exhibited between the voids and supports; certain it is that in every case the former exceed the latter, and that, in the early Dorics, the ratio between them nearly approached equality. In comparing, however, the supports with the weights, there is every appearance of that portion of the theory being strictly true; for, in taking a mean of the six examples of the Doric order, the supports are to the weights as 1 : 1·16; in the five of the Ionic order, as 1 : 1·05; and in the four of the Corinthian order, as 1 : 1·04; a coincidence so remarkable that it must be attributed to something more than accident, and deserving much more extended consideration than our limits here admit.

	Order.	No. of Columns.	Supports.	Weights.	Voids.
Temple of Jupiter Nemæus -	Doric	6	1·00	0·79	1·03
Parthenon - - - -	—	8	1·00	1·07	1·04
Temple at Bassæ - - -	—	6	1·00	1·14	1·16
of Minerva, at Sunium	—	6	1·00	1·40	1·17
of Theseus, at Athens -	—	6	1 00	1·13	1·21
of Jupiter Panhellennis	—	6	1·00	1·45	1·36
Temple of Erectheus - -	Ionic	6	1·00	0·89	1·24
of Fortuna Virilis - -	—	4	1·00	1·15	1·71
on the Ilyssus - -	—	4	1·00	0·96	1·72
of Bacchus, at Teos -	—	8	1·00	1·35	2·05
of Minerva Polias -	—	4	1·00	1·01	2·18
Portico of Septimius Severus -	Corinth.	6	1·00	0·93	1·37
Maison Carrée - - -	—	6	1·00	0·93	1·58
Temple at Jackly - - -	—	6	1·00	0·90	1·62
Pantheon - - -	—	8	1·00	1·43	1·84

We close this short inquiry by adverting to a curious fact connected with it; viz. the area of the points of support for the edifice which such an arrangement affords. In fig. 7. the hatched squares represent the quarter piers or columns in a series of intercolumniations every way, such intercolumniations being 2 diameters, or 4 semidiameters: these, added to the 2 quarter piers, will make 6, whose square, 36, therefore, is the area to be covered with the weight; the 4 quarter piers or columns = 4; hence the points of support are $\frac{4}{36}$ of the area = 0·111.

(7.)



Now, in twenty-five of the principal buildings in Europe (*see* POINTS OF SUPPORT), the ratio will be seen to be 0·168 on the mean, differing only 0·057 from the result here given; but if we take the subjoined buildings, the mean will be found to differ much less, viz.—

ORDER OF SUPERPOSITION. A Geological term, implying the regular succession of arrangements which the strata forming the exterior crust of our globe invariably follow. (*See* GEOLOGY.) Although certain strata or formations are occasionally wanting, they never depart from a constant order of superposition.

ORDER OF THE DAY. In Parliamentary usage, one method of superseding a question already proposed to the House is by moving "for the order of the day to be read." This motion, to entitle it to precedence, must be for the order generally, and not for any particular order; and, if this is carried, the orders must be read and proceeded on in the course in which they stand. But it can be in its turn superseded by a motion "to adjourn." See *Hatsell's Prec. Parl.* vol. ii., who says that the first instance he has met with of this proceeding was on the 1st of April, 1747.

ORDERS, HOLY. A term, properly speaking, applied to the different ranks of ecclesiastical persons; but, in ordinary language, used to indicate the *character* of such persons. The Roman Catholic church admits of seven orders: four minor, secular, or petty, of doorkeeper, exorcist, reader, and acolyth; three major, of deacon, priest, and bishop. The first are mere formalities, and generally conferred on the same day; the admission to the latter constitutes the sixth sacrament of Romanism: the Reformed churches acknowledge only the three latter orders. (*See* EPISCOPACY.) The Greek church rejects the four minor, but has the additional one of sub-deacon. *See* ORDINATION.

OR'DERS, RELIGIOUS, are of three kinds; 1. Monastic, 2. Military, 3. Mendicant.

1. The Monastic orders were distinguished by the rules to which they were subjected by their respective founders. Of these the principal are the Basilian, the Benedictine, and the Augustinian.

i. The earliest comprehension of a number of conventual societies under one rule was effected by St. Basil, archbishop of Cæsarea, in Asia Minor, who united the hermits and cenobites already established in his diocese, and prescribed an uniform constitution for them, in which he strongly recommended the obligation of a vow upon admission. This recommendation was a novelty in the monastic system, which had existed up to that time (A. D. 370.) without any such imposition. This institution prevailed throughout the eastern districts of Christendom, and has subsisted in the Greek church up to the present time with little variation.

ii. In the West, the first order of monks was founded by Benedict of Nursia (A. D. 529). He conceived that the ends of monastic seclusion might be better attained by a milder discipline, uniformly imposed, than by the fanatical and arbitrary austerities of many of the European communities. While other reformers of the monkish system have aimed at repairing its laxity and degeneracy by the infusion of greater strictness and severity, he alone seems to have adopted a contrary course, and to have provided for the attainment of more real excellence by the imposition of milder obligations. He insisted, moreover, very strongly, upon the duties of manual labour and reading, as well as of prayer; and gave, as was the custom with other founders, minute directions for the employment of the day. This rule was revised three centuries later by another Benedict, a native of Ariane, in the south of France.

From this remodelled system, which was more severe than its predecessor, and was soon adopted throughout the Benedictine monasteries, already exceedingly numerous, arose various branches, all more or less famous in ecclesiastical history. The order of Cluni, the Cistercians, the Chartreux, the Camaldulenses, Præmonstratenses, &c. are distinct off-shoots from this main trunk,

and for many centuries have covered the face of Catholic Europe.

iii. The original inhabitants of the monasteries were laymen; the spiritual duties of the institution being performed by the pastor of a neighbouring village, or by one or two resident ecclesiastics. St. Augustin set the example of a clerical society, by living, in common with his inferior clergy, under certain instructions which he drew up for their direction. His authority was widely followed in later times; and the order of Augustinian canons, consisting expressly of persons ordained or destined to the sacred profession, claims a place among the three principal monastic institutions. These canons were afterwards divided into the regular and secular, according as they observed what tradition affirmed to be the rule prescribed by the founder himself, or those of certain bishops who, in later times, had reorganized the system.

2. i. The Military orders form also an important feature in ecclesiastical and political history. The necessity which the monks were under, in unsettled times, of assuming arms themselves to defend the possessions which they had accumulated, may have suggested the first idea of uniting the military with the religious profession.

The earliest order, however, of this kind — that of St. John of Jerusalem, or the Knights of the Hospital — arose, in the 11th century, out of a religious community, to which the care of an hospital in Jerusalem had been consigned. The Hospitallers were afterwards better known under the titles of Knights of Rhodes, and, still later, of Malta.

ii. The Knights Templars also received their appellation from Jerusalem, the place of their origin and early abode. They were founded in 1118; and to them certain military duties were from the first specially prescribed, as the defence of Palestine, and the protection of pilgrims in the Holy Land. After the expulsion of the Christian arms from that region, they spread over Europe, and became a very numerous and powerful body; until, having excited the fears or avarice of popes and princes, they were condemned by a council assembled at Vienna, and exterminated by a vigorous and cruel persecution.

iii. The third Military order is the Teutonic. This institution, again, was an offspring of the crusades, and a native of Palestine; originating in the officer of an hospital at the siege of Acre. On the termination of the holy wars, these knights became established in Germany, and distinguished themselves by the conquest and conversion of Prussia and Pomerania. Their order only ceased to exist when, at the Reformation, its members abandoned the cause of the papacy, and embraced the prevalent opinions of the north of Germany. To these may be added various inferior military orders, especially those of Spain and Portugal. *See* Calatrava and Alcantara, Orders of.

3. i. The Mendicant orders were the creation of the papacy, for the advancement of its own political purposes. It was in the 12th century that the apprehensions of the holy see were first excited by the rise and spread of heretical opinions; nor, at that period, were either the secular or the regular clergy disposed to rouse themselves from their indolence and vice to combat with these active assailants. The counteracting force, also, which the monks had supplied, in earlier ages, to the independent spirit of the secular priesthood, had lost much of its efficacy, and in some measure been turned against the central authority of Rome. A new ally was required, and was furnished in the order of St. Dominic, which, after completing its first mission in the extinction of the heresy of the Albigenses, was placed upon a permanent footing by a bull of Honorius III.

ii. The Franciscan friars were of cotemporary institution, and avowed the same principle of poverty and mendicity. Our limits allow us merely to mention — iii. The Carmelites (who derived their name from Mount Carmel, in Syria, where the order originated); iv. The Augustinians, who complete the number of the Mendicant orders; and, v. The Jesuits. *See* Jesuits.

O'RDINAL, or ORDER. The name given in England to an old work containing the ritual or religious ceremonies necessary to be performed before the ordination of a priest. It was composed in the reign of Edward VI., and revised by the English clergy in 1552.

O'RDINANCE. An obsolete word signifying a decree or enactment. After the time of Philip le Bel (1227), the laws made by French kings were generally termed ordinances (ordonnance); a term which, in its most comprehensive sense, included also their edicts, declarations, and letters patent. The right to issue ordinances for the execution of the laws (equivalent to proclamations and orders in council) is conferred on the monarch by the French charters; and it was on an ambiguity of language in the clause conferring this right in that of 1814, that a defence was attempted for the illegal proceedings of the ministers of Charles X. in 1830. The best collection of the *Ordonnances des Rois de France* is that begun by order of Louis XIV., of which the first volume appeared in 1723: it extends to 12 vols. folio.

The Self-denying Ordinance, in English History, was a resolution of the Long Parliament, in 1644, by which its members bound themselves not to take certain executive offices, particularly commands in the army; the effect of which, as is well known, was the transference of power, first in the the army, and then in the state, from the Presbyterian to the Independent party.

O'RDINAND. (Lat. ordinandus.) In Ecclesiastical Antiquities, one about to receive orders. — *Ordinant.* a prelate conferring orders.

O'RDINARY. A term of the Civil Law for any judge who has authority to take cognizance of causes in his own right, and not by delegation; used, in English law, with reference to ecclesiastical judges only. Thus, a bishop is ordinary in his own diocese; an archbishop, for the purpose of appeals, in his province.

Ordinary. In the Court of Session in Scotland, a single judge (by courtesy styled lord), who decides with or without a jury, as the case may be. There are five such judges: their decisions may be brought by appeal under review of the divisions of the court to which they respectively belong. *See* Session, Court of.

Ordinary. In the Navy, the establishment of the shipping not in actual service.

Ordinary, in Heraldry, is a portion of the escutcheon comprised between straight or other lines. It is the simplest species of charge; and many of the most ancient escutcheons known contain no other bearing, although in others, also of great antiquity, the ordinary itself is charged with other bearings. An ordinary should, it is said, comprise the fifth of the shield. The number of ordinaries in common use is considerable; among the chief are the pale, fess, bend, bar, saltier, chevron, cross (which see). Each of these is usually bounded by straight lines; but the lines may be also diversified in various manners. Thus, an ordinary bounded by serrated lines is said to be *indented*; bounded by undulating lines, *wavy*; and there are many other deviations from the straight line, as *ingrailed, invected, nebuly, raguly, rayonny, dancetty, embattled* or *crenelly, battled embattled, palissy, angled, levelled, escartely, nowy, dovetail, potency*. When an ordinary has two sides, and is only varied on the upper, it is said to be *superingrailed, superinvected,* &c.; if only on the lower, *subingrailed*, &c.

Ordinary, of Newgate. The clergyman who officiates in this prison is so called, whose duties consist in preaching and reading prayers to the prisoners, preparing condemned criminals to meet their fate, and in accompanying such to the place of execution.

O'RDINATE. (Lat. ordino, *I arrange*.) In Geometry, a straight line drawn from any point in a curve perpendicularly to another straight line, which is called the abscissa. (*See* Absciss.) The absciss and ordinate together are called the *co-ordinates* of the point. The situation of a point in a plane is determined when its distances from two straight lines in the same plane are known; and, when a series of points are so situated in respect of each other that the co-ordinates of each have the same mathematical relation, these points form a curve, the nature of which is expressed by the relation of the co-ordinates. *See* Co-ordinates.

ORDINA'TION. The ceremony of conferring orders in the church, which is derived, by all communities that admit a regular commission and succession in the ministry from the time of the apostles, from the authority of Jesus Christ; of whom it is said, in St. John's Gospel (xx. 21.), that, after his resurrection, he said, "As my father has sent me, even so send I you:" and then he breathed upon them, and said to them, "Receive ye the Holy Ghost: whose soever sins ye remit they are remitted unto them, and whatsoever sins ye retain they are retained." Prayer and the imposition of hands are also mentioned as forming part of the ceremony of ordination of deacons in the Acts; and ordination is even now conferred under similar forms in most Christian churches.

The Romish church holds ordination to be the sixth of its seven sacraments, as being an institution of Christ conferring a special grace. The Protestants show that it differs from a sacrament, according to the received definition of such, as containing no matter, like the water in baptism, or the elements in the eucharist. They deny that the vessels which are delivered to the newly ordained person according to the Romish rite can be taken as the matter of a sacrament, not being recommended by any Scripture authority, nor indeed known in the church till the tenth or eleventh century. (See *Hooker's Eccl. Pol.* books vii. and viii.)

In the Presbyterian church the term *ordination* has a meaning wholly distinct from that in which it is received by other Christian churches; being applied exclusively to that solemn act by which a *licensed* preacher or probationer is inducted into the charge of a particular parish or congregation, and not, as is sometimes erroneously asserted, to the act by which he is entitled to preach the Gospel, or, in other words, to the ceremony by which "orders" are conferred in the English church. In the English church a clergyman can be *ordained* but once: in the Scotch church he is said to be *ordained* as

often as he leaves one parish to be inducted into the charge of another.

O'RDNANCE. A Military term, applied generally to all sorts of great guns used in war, as cannons, mortars, howitzers, carronades, &c. See the respective terms.

O'RDNANCE, BOARD OF. The name given to the board which provides the troops of the line, the regiments of artillery and engineers, the militia, volunteers, and the navy, with guns, ammunition, and arms of every description. The Board of Ordnance also superintends the affairs of the regiments of artillery and engineers, the provision of forage for the whole of the troops at home, and the erection of fortifications and military works at home and abroad, &c. At the head of this board is placed an officer, called the Master-general of the ordnance, who has the military command of the artillery, and of the corps of royal engineers and sappers and miners. Besides the Master-general, the other chief officers connected with the ordnance are the Surveyor-general, the Clerk of the ordnance, and the Storekeeper of the ordnance, which are self-explanatory terms.

O'RDONNANCE. (Fr.) In Architecture, the right assignment, for convenience and propriety, of the measure of the several apartments, that they be neither too large nor too small for the purposes of the building, and that they be conveniently distributed and lighted.

O'READS. (Gr. ὄρος, *mountain*.) In Greek Mythology, nymphs of the mountains, companions of Diana, and usually invoked along with that goddess.

ORES. (Germ. erze.) The mineral bodies from which metals are extracted. Metals exist in the ores in one or the other of the four following states:—1. In a metallic state, and either solitary or combined with each other; in the latter case forming alloys. 2. Combined with sulphur, forming sulphurets. 3. Combined with oxygen, forming oxides. 4. Combined with acids, forming carbonates, phosphates, &c., which generally go by the name of metallic salts.

Certain ores which contain the metals most indispensable to human necessities have been treasured up by the Creator in very bountiful deposits; constituting either great masses in rocks of different kinds, or distributed in lodes, veins, nests, concretions, or beds with stony and earthy admixtures; the whole of which become the objects of mineral exploration. These precious stores occur in different stages of the geological formations; but their main portion, after having existed abundantly in the several orders of the primary strata, suddenly cease to be found towards the middle of the secondary. Iron ores are the only ones which continue among the more modern deposits, even so high as the beds immediately beneath the chalk, when they also disappear, or exist merely as colouring matters of the tertiary earthy beds.

The strata of gneiss and mica-slate constitute in Europe the grand metallic domain. There is hardly any kind of ore which does not occur there in sufficient abundance to become the object of mining operations, and many are found no where else. The transition rocks, and the lower part of the secondary ones, are not so rich, neither do they contain the same variety of ores. But this order of things, which is presented by Great Britain, Germany, France, Sweden, and Norway, is far from forming a general law; since in equinoxial America the gneiss is but little metalliferous; while the superior strata, such as the clay-schists, the sienitic porphyries, the limestones, which complete the transition series, as also several secondary deposits, include the greater portion of the immense mineral wealth of that region of the globe.

All the substances of which the ordinary metals form the basis, are not equally abundant in nature; a great proportion of the numerous mineral species which figure in our classifications are mere varieties scattered up and down in the cavities of the great masses or lodes. The workable ores are few in number, being mostly sulphurets, some oxides, and carbonates. These occasionally form of themselves very large masses, but more frequently they are blended with lumps of quartz, felspar, and carbonate of lime, which form the main body of the deposit; as happens always in proper lodes. The ores in that case are arranged in layers parallel to the strata of the formation, or in veins which traverse the rock in all directions, or in nests or concretions stationed irregularly, or finally disseminated in hardly visible particles. These deposits sometimes contain apparently only one species of ore, sometimes several, which must be mined together, as they seem to be of contemporaneous formation; whilst, in other cases, they are separable, having been probably formed at different epochs. Under the particular metals will be found an account of the localities of ores, &c.; but the following general observations may prove useful in presenting a condensed resumé of the whole subject.

1. *Tin* exists principally in primitive rocks, appearing either in interlaced masses in beds, or as a constituent part of the rock itself, and more rarely in distinct veins. Tin ore is found indeed sometimes in alluvial land, filling up low situations between lofty mountains.

2. *Gold* occurs either in beds or in veins, frequently in primitive rocks; though it is also found in other formations, and particularly in alluvial earth. When this metal exists in the bosom of primitive rocks, it is particularly in schists; it is not found in serpentine, but it is met with in greywacke in Transylvania. The gold of alluvial districts, called gold of washing or transport, occurs, as well as alluvial tin, among the debris of the more ancient rocks.

3. *Silver* is found, particularly in veins and beds, in primitive and transition formations; though some veins of this metal occur in secondary strata. The rocks richest in it are gneiss, mica-slate, clay-slate, greywacke, and old alpine limestone. Localities of silver-ore itself are not numerous, at least in Europe, among secondary formations; but it occurs in combination with the ores of copper or of lead.

4. *Copper* exists in the three mineral epochas:—1. In primitive rocks, principally in the state of pyritous copper, in beds, in masses, or in veins; 2. In transition districts, sometimes in masses, sometimes in veins of copper pyrites; 3. In secondary strata, especially in beds of cupreous schist.

5. *Lead* occurs also in each of the three mineral epochas; abounding particularly in primitive and transition grounds, where it usually constitutes veins, and occasionally beds of sulphuretted lead (galena). The same ore is found in strata or in veins among secondary rocks, associated now and then with ochreous iron-oxide and calamine (carbonate of zinc); and it is sometimes disseminated in grains through more recent strata.

6. *Iron* is met with in four different mineral eras, but in different ores. Among primitive rocks magnetic iron ore and specular iron ore occur chiefly in beds, sometimes of enormous size: the ores of red or brown oxide of iron (hæmatite) are found generally in veins, or occasionally in masses with sparry iron, both in primitive and transition rocks; as also sometimes in secondary strata; but more frequently in the coal-measure strata, as beds of clay-ironstone, of globular iron oxide, and carbonate of iron. In alluvial districts, we find ores of clay-ironstone, granular iron-ore, bog-ore, swamp-ore, and meadow-ore. The iron ores which belong to the primitive period have almost always the metallic aspect; with a richness amounting even to 80 per cent. of iron, while the ores in the posterior formations become in general more and more earthy, down to those in alluvial soils, some of which present the appearance of a common stone, and afford not more than 20 per cent. of metal, though its quality is often excellent.

7. *Mercury*, as a sulphuret, occurs principally among secondary strata in disseminated masses, along with combustible substances; though the metal is met with occasionally in primitive countries.

8. *Cobalt* belongs to the three mineral epochas; its most abundant deposits are veins in primitive rocks; small veins containing this metal are found, however, in secondary strata.

9. *Antimony* occurs in veins or beds among primitive and transition rocks.

10, 11. *Bismuth* and *nickel* do not appear to constitute the predominating substance of any mineral deposits; but they often accompany cobalt.

12. *Zinc* occurs in the three several formations; namely, as sulphuret, or blende, particularly in primitive and transition rocks; as calamine, in secondary strata, usually along with oxide of iron, and sometimes with sulphuret of lead.

In the analysis of ores, it is impossible to lay down any general rule, so numerous are the ores themselves, and so diversified the means necessary to be adopted in the various analytic processes. Under each particular metal will be found an account of its most important ores, and we shall here restrict ourselves to a few general remarks on the theory of smelting ores.

It is probable that the coaly matter employed in that process is not the *immediate* agent of their reduction; but the charcoal seems first of all to be transformed by the atmospherical oxygen into the oxide of carbon, which gaseous product then surrounds and penetrates the interior substance of the oxides, with the effect of decomposing them, and carrying off their oxygen. That this is the true mode of action, is evident from the well-known facts that bars of iron, stratified with pounded charcoal, in the steel-cementation chest, most readily absorb the carbonaceous principle to their innermost centre, while their surfaces get blistered by the expansion of carburetted gases formed within; and that an intermixture of ores and charcoal is not always necessary to reduction, but merely an interstratification of the two, without intimate contact of the particles. In this case, the carbonic acid which is generated at the lower surfaces of contact of the strata, rising up through the first bed of ignited charcoal, becomes converted into carbonic oxide; and this gaseous matter, passing up through the next layer of ore, seizes its oxygen, reduces it to metal, and is itself thereby transformed once more into carbonic acid; and

so on in continual alternation. It may be laid down, however, as a general rule, that the reduction is the more rapid and complete the more intimate the mixture of the charcoal and the metallic oxide has been, because the formation of both the carbonic acid and carbonic oxide becomes thereby more easy and direct. Indeed the cementation of iron bars into steel will not succeed, unless the charcoal be so porous as to contain, interspersed, enough of air to favour the commencement of its conversion into the gaseous oxide; thus acting like a ferment in brewing. Hence, also, finely pulverized charcoal does not answer well, unless a quantity of ground iron cinder or oxide of manganese be blended with it, to afford enough of oxygen to begin the generation of carbonic oxide gas; whereby the successive transformations into acid and oxide are put in train. (For these observations we are indebted chiefly to *Ure's Dict. of Arts, &c.*, arts. "Mine" and "Ores.") See also the art. GEOLOGY in this work.

ORE'XIS. (Gr. ὀρέγομαι, *I labour.*) A term applied in medicine to the appetite, or a sense of hunger.

O'RFRAIES. (Fr. orfrois, *broad welts of gold.*) A species of embroidered cloth of gold, worn anciently by the kings and nobles of England. This name was also given to the clothes worn by the king's guards, which were also embroidered with gold.

O'RGAN. (Gr. ὄργανον, *an instrument.*) In Music, a wind instrument; so called by way of eminence, being indeed perhaps less an instrument than a machine containing a collection of instruments, or, in other words, a mechanical orchestra, under the command of a single performer's fingers on the keyboard. This instrument was invented at an early period, though until the eighth century it was probably but little used. The Greeks appear to have been acquainted with it; and, in the tenth book of his *Architecture*, Vitruvius describes an hydraulic organ which was played, or rather blown, by the fall of water, but in what precise manner is not now known. The emperor Julian eulogises this instrument in an epigram; and St. Jerome speaks of one, with twelve pair of bellows, which might be heard at the distance of a thousand paces; and of another, at Jerusalem, which might be heard at the Mount of Olives. Its invention is attributed to Ctesibius, a barber of Alexandria.

The size of an organ is usually expressed by the length of its largest pipes; thus an organ of 32 feet, of 16 feet, &c., is one whose lowest bass pipes are of those respective lengths. Church organs consist of two parts; viz. the great organ, which comprises the main body; and the chair, or choir organ, a smaller one, commonly placed before the other. The organ is provided with at least one set of keys; and when it has a chair organ and a swell organ, with two, three, or even more. Besides these there are pedals for the lowest pipes, and composition pedals, which change the stops as required at one pressure; both of these are acted upon by the feet. There is another pedal to open the swell organ with the right foot. The key boards of organs vary in extent: the York has 6 octaves from C C C (16 feet) to C in alt; the Birmingham 5½ octaves; but the compass now in general use, here and on the Continent, is from C C (8 feet) to F in alt, 4½ octaves; the lower notes from C C to C C C (16 feet) being placed on the pedal organ. The G G compass is gradually falling into disuse, a compass which never prevailed on the Continent. Each key, being pressed down with the finger, opens a valve or plug, corresponding lengthwise with as many holes as there are rows of pipes on the sound board; and the holes of each row are opened and shut by a register or ruler pierced with holes equal in number to the keys. By drawing the register the holes of one row are opened, because they correspond with those of the sound board; so that, by opening a valve, the wind brought to the sound board by means of bellows finds its passage into the pipes which correspond to the open holes of the sound board. By pushing the register or stop, the holes therein not answering to any of those of the sound board, the row of pipes answering to the register so pushed is shut. It is obvious, therefore, by drawing several of these registers or stops, correspondent rows of pipes are opened: hence the rows of pipes become simple or compound; the former when only one row answers to one register, the latter when several do so. Organists call a row compound when several pipes play upon pressing one stop.

Organ pipes are of two sorts, mouth pipes and reed pipes, of each of which there are several species. The first, called pipes of mutation, consist, first, of a foot, which is a hollow cone, and receives the wind that sounds the pipe; second, the body of the pipe, which is fastened to the foot. Between the foot and the body of the pipe is a diaphragm or partition, having a little long narrow aperture to let out the wind; over this aperture is the mouth, whose upper lip, being horizontal, cuts the wind as it escapes through the aperture. The pipes are made either of pewter, of lead mixed with a certain portion of tin, or of wood. The tin pipes are always open at their extremities, are of very small diameter, and clear and shrill in their sound. Those of lead and tin mixed are larger, the shortest open, and the longest quite stopped; the medium ones are partly stopped, and have besides a little ear on each side of the mouth, drawn close or set farther apart, for the purpose of raising or lowering the sound. The wooden pipes are made square on the plane, and their extremities are stopped with a valve or tompion covered with leather, so as to be air-tight. The sound of these is very soft. The large pipes stopped are usually of wood, the small ones of lead. Of course the longest yield the gravest, the shortest the most acute sounds. Their lengths and widths are in the reciprocal ratio of their sounds; and the divisions regulated by their rule, which is called the diapason. The pipes, however, which are shut have the same length as those that are open, which give the same sound.

The reed pipes consist of a foot to carry the wind into the shallot or reed, a hollow half cylinder, whose extremity is fitted into a kind of mould by a wooden tompion. Its other extremity is at liberty; so that the wind, entering the shallot, causes it to vibrate or shake against the reed; and the longer that part of the tongue which is at liberty is made, the deeper the sound. The mould serving to fix the shallot or reed, the tongue, tompion, &c. serves also to stop the foot of the pipe, and to compel the wind to escape wholly at the reed. In the mould, the part called the tube is soldered, the inward opening whereof is a continuation of the reed. The form of the tube varies in different ranks of pipes. The acuteness and gravity of a reed pipe depends on the length of the tongue, and of that of the pipe, taken from the extremity of the shallot to the extremity of the tube. The quality of the sound depends on the width of the reed, the tongue, and the tube; and also on the thickness of the tongue, the figure of the tube, and the quantity of wind. To vary the character of the sound of the pipes a valve or portvent is added, which introduces the wind by fits and shakes.

At Ulm, there is an organ in the cathedral 93 feet high and 28 broad; its largest pipe is 13 inches in diameter, and it is supplied with sixteen pair of bellows. This organ, however, is surpassed by the famous one at Haarlem, which is 103 feet high and 50 feet broad, and was made in 1738 by Christian Muller. The great organ, or manual, contains sixteen stops or voices; the upper manual fifteen stops; the chair organ fourteen stops; and to the pedals, of which the deepest pipe is 38 feet long, and 15 inches in diameter, there are fifteen stops; being, in all, sixty voices or stops, two tremblans, two accouplemens, and nearly five thousand pipes. The bellows are each 9 feet long and 5 feet broad. The organ at Rotterdam is also on a very large scale, and not greatly inferior to that just described; its reed stops, indeed, are allowed to be superior.

At the period of the restoration of Charles II. the organs of this country had fallen much into decay, and the art of building them was then renewed here by the celebrated Bernard Schmidt, who, to distinguish him from his nephews, Gerard and Bernard, by whom he was accompanied, obtained the name of Father Smith; and by Harris, from France. The celebrated organ at the Temple church was built by the first-named person.

The science of organ-building has of late years again revived in this country, and indeed in other parts of Europe. The three largest organs in England are in York Minster, the Town Hall, Birmingham, and Christ Church, London. The first-named, by Messrs. Elliot and Hill, has a compass from C C C to C in alt, that is, 6 octaves. The great organ has 24 stops, 4 open diapasons 16 feet, four 16 feet reeds. The choir has 10 stops, from C C C to C in alt. The compass of the swell is from C C to C in alt, and it contains 12 stops. The pedal organ has 10 stops compass; 2 octaves 32 feet to 8 feet, 32 feet open diapason metal, do. wood, and do. trumpet; three 16 feet reed stops, four 16 feet diapason to 4 feet. There are in all 56 stops, 6 couples, and 7 composition pedals to shift the stops. There are 4089 pipes in 50 ranks.

The organ at the Town Hall in Birmingham, which was built by Mr. Hill, has a compass from C C C to F in alt. There are 4 rows of keys, and 2 octaves of keys, to play the double pedal-pipes with the fingers, on the bass side of the movements. The great organ contains the following stops: 3 open diapasons to 16 feet C, double diapason, and stopped diapason; 2 principals of metal, and 2 of wood; a twelfth and 2 fifteenths of metal, 1 of wood; a reed fifteenth 4 feet, posaune on a large scale (16 feet), trumpet 16 feet, clarion 8 feet, sesquialtra 4 ranks, mixture 3 ranks; two octaves of German pedals; thirty-two feet metal open diapason to 8 feet C; thirty-two feet wood open diapason to 8 feet C; two octaves of pedal trumpets 16 feet to 8 feet C. The 32 feet pipe with the remainder of the 2 octaves of double pedal pipes are in front. The choir organ from C C C (16 feet) to F in alt has open and stopped diapasons, principal, harmonia, flute, fifteenths, cremona, and bassoon, open diapason wood, and dulciana. Swell descends to C C, and has

open, double, and stopped diapason, principal, fifteenth, harmonica, horn, trumpet, hautboy, and clarion.

The ophicleide, or tuba mirabilis, on the swell manual from C C to F, the same compass as the swell, but separate from it, forms its prominent feature, having power equal to the whole of the great organ, with a full, fine, and smooth tone. This magnificent reed is unparalleled in Europe; and the Birmingham and Liverpool organs are the only instruments which can boast of its powers.

The first clavier is the choir, the second the great organ, the third the swell; the fourth clavier takes any single stop, or all of them, in either choir or swell, without affecting either, or, in other words, the performer may play the choir and swell in the usual manner, without at all affecting the fourth clavier. To accomplish the mechanical movement requires more draw stops than real stops of pipes, although the same object is gained by the fourth clavier as by a fourth separate organ. The collected lengths of the trackers, or wood rods, which communicate from the keys to the sound boards, would extend four miles and a half. The 32 feet C is 1 foot $8\frac{1}{2}$ inches in diameter: the same note, in wood, 3 feet by 2 feet 6 inches, and would hold 12 pipes and 13 gallons of wine. There are two octaves and a half of bells. The pedal pipes are played with the fingers, as easily as the great organ, by a newly invented valve * which resists the pressure of wind. There are at present 63 draw stops in this organ, including the tuba mirabilis recently inserted, and including coupler stops. The choir and swell have 2 draw stops to each row of pipes, as the fourth clavier may require.

The Christ Church organ, in Newgate-street, London, which is yet in progress, will be the largest manual organ in Europe, containing 71 stops; 24 in the great organ, 17 in the choir, 11 in the swell, 10 in the pedal organ, and 8 copulas. This was commenced by Mr. Hill in 1840. The two largest swell organs in Europe have been erected by Mr. Hill during the present year. The one is in St. Peter's Church, Cornhill, and contains 19 stops; the other is in the new Independent Chapel, Liverpool, and contains 20 stops. These swell organs are about double the size of those in the York and Birmingham organs, and contain many new stops; such as the wold flute, suabe flute, oboe flute, echo dulciana cornet, piccolo, and other qualities of tone hitherto unknown in this country.

ORGAN POINT. In Music, a succession of chords, in some of which the harmony of the fifth is taken unprepared on the bass as a holding note, whether preceded by the tonic or by the harmony of the fourth of the key.

ORGA'NICAL DESCRIPTON OF CURVES, in Geometry, signifies the description of curves on a plane by means of instruments; as the circle is described by a pair of compasses, the ellipse by means of a thread passing round two pins in the foci, the epicycloids by the revolution of circles on the circumferences of other circles, the conchoid by means of the *trammel*, the cissoid by the motion of a rectangular ruler, &c. See *Schooten's Exercitationes Mathematicæ; Newton's Arith. Universalis; Maclaurin's Geometria Organica*, &c.

ORGA'NIC DISEASE. A disease in which the structure of an organ is morbidly altered; opposed to *functional* disease, in which the secretions or functions only are deranged, without any apparent change of organization. Tuberculated induration of the liver is an *organic* or *structural* disease of that viscus: the secretion of viscid unhealthy bile is a *functional* derangement of it.

ORGA'NIC LAWS. In Modern Political Phraseology, the name given to laws directly concerning the fundamental parts of the constitution of a state. According to the distinction taken by some French writers, fundamental laws are merely declaratory, containing the principles or theory of government. Organic laws are those which apply those principles to the actual condition of society by positive enactment, and add the sanction of punishment.

ORGA'NIC REMAINS. The organized bodies, whether of animals or vegetables, found in a fossil state, are so called. *See* GEOLOGY.

O'RGANISTS. The old name given in the Roman Catholic Church to those priests who organized or sang in parts. The name *organists of the hallelujah* was applied in the 13th century to certain priests who assisted in the performance of the mass. They were generally four in number, and derived their name from singing in parts, or organizing the melody appropriated to the word hallelujah.

ORGANIZA'TION. (Lat.) The processes by which an organized body is formed: also the totality of the parts which constitute, and of the laws which regulate, an organized body.

ORGANO'GRAPHY. (Gr. οργανον, *a tool* or *instrument*, and γραφω, *I describe.*) A term usually applied to an account of the structure of plants. It comprises all that relates to the various forms of tissue of which plants are anatomically constructed; explains the exact organization of all those parts through which the vital functions are performed; and teaches the relation which one part bears to another, with the dependence of the whole upon the common system. *See* BOTANY.

O'RGANON. (Gr. οργανον.) In Philosophical language, nearly synonymous with *method*, and implying a body of rules and canons for the direction of the scientific faculty, either generally or in reference to some particular department. For an account of the *Organon* of Aristotle and that of Bacon, see articles ARISTOTELIAN and BACONIAN PHILOSOPHY respectively.

O'RGIES. (Gr. ὀργια.) In Mythology, the mysteries of Bacchus, as solemnized among the Greeks and Thracians. Writers derive the name from the word οργη, *anger*, from the fury and excitement of the Bacchanals, or from the wrath of Ceres against Jupiter. (*Clem. Alex.*) But these fanciful etymologies, after the manner of the Greeks, seem to show that the word was really of foreign origin, and adopted by them together with the thing itself. The author of the article "Mysteries" in the *Encyc. Brit.* would derive it from Hebr. argoz, *a chest*, from the casket containing the secret symbols of the god. According to his view, the orgies were the mysteries of Osiris, the Egyptian Bacchus, and from Egypt transplanted to Greece, where they became mingled with the gross corruptions peculiar to the worship of the Bacchus of Thebes. Others imagine their origin to have been in Thrace. The frantic solemnities of these rites are most poetically described in the *Bacchæ of Euripides*. The mysteries which they enveloped are extremely obscure.

ORGUES. In Fortification, long and thick pieces of wood shod with iron, and suspended each by a separate rope over a gate so as to be ready to be let fall and stop it up upon the approach of an enemy. The term also denotes a machine composed of arquebuses, or musket-barrels, linked together so that they may be discharged all at once, and used to defend breaches.

ORGY'IA. (Gr. οργυω, *I stretch out*, and γυιον, *a limb.*) A name applied by Ochsenheimer to a genus of Lepidopterans.

ORICHA'LCUM. (Gr. ορος, *a mountain*, and χαλκος, *brass.*) Literally, mountain brass. This was the name given to a peculiar kind of mixed metal in general use among the ancient Greeks and Romans. It is proved to have been made on much the same basis as brass; but various opinions have been entertained respecting the precise nature of the ingredients employed in its composition, and no definite conclusion has been arrived at on the subject.

O'RIEL. (Etym. uncertain.) In Gothic Architecture, a bay window. According to some passages in early writers, it seems also to signify a recess; but the former is the signification now usually attached to it.

O'RIENT. (Lat. orior, *I rise.*) The east, or eastern part of the horizon. In surveying, *to orient* a plan signifies to mark its situation or bearing with respect to the four cardinal points.

O'RIFLAMME. The ancient royal standard of France. It was the banner of the abbey of St. Denis, which was presented by the abbot to the lord-protector of the convent, whenever engaged in the field on its behalf. This protectorship was attached to the countship of Vexin; and when that county was added to the possessions of the crown by Philip I. this banner, which he bore in consequence, became in time the great standard of the monarchy. By some it is said to have been lost at Agincourt; but, according to others, its last display in the field was in the reign of Charles VII. Its derivation is uncertain: according to some, "quasi auri flamma." According to Count de Gebelin, the last syllable is the same with "fanon" (Germ. fahne). Felibien says it was still to be seen, in 1535, in an abbey, almost devoured by moths. (See *Mem. de l'Ac. des Inscr*. vol. xiii.)

ORI'GANUM, OIL OF. The distilled or volatile oil of the wild marjoram. It is imported from the south of Europe, and used in liniments and embrocations as a stimulant.

ORI'GENISTS. An early Christian sect, who pretended to draw their opinions from the writings of the celebrated Origen. They maintained that Christ was the Son of God only by adoption; and denied eternity of punishments. They existed in considerable numbers in the fourth, fifth, and sixth centuries; and their tenets spread among the monks of Egypt. This sect of Christians must by no means be confounded with the Origenarians, who sprang up at a somewhat later period than the former, and whose tenets surpassed in abomination even those of the Gnostics. (See *Mosheim* (transl.), ed. 1790, i. 392.)

ORI'GINAL. (Lat. originalis.) In Law, where the several parts of an indenture are interchangeably executed between the parties, that part which is executed by the grantor is commonly called the original, the others counterparts. (*See* INDENTURE, COUNTERPART.) But, when all

* For this valve Mr. Hill had the silver medal awarded to him by the Society for Promoting Arts and Commerce, May 31st, 1841.

the parties execute every part, all are originals. The *original* of any deed or document is the best evidence; and a copy not admitted until reasonable proof has been given that the former is destroyed, lost, &c., or that it is in the possession of the adverse party, who has been duly warned to produce it. (*See* Evidence.) The writ which a plaintiff sued out of chancery, in order to commence a suit, was formerly called an "original writ;" the use of it is abolished, in personal actions, by 2 W. 4. c. 39. *See* Pleading.

Original. In the Fine Arts, a work not copied from another, but the work of the artist himself. When an artist copies his own work, it is called a duplicate. A certain freedom and ease are always discernible in an original, which in a copy are looked for in vain; though copies have sometimes been executed which it is almost impossible to detect, and which have deceived even excellent judges.

ORI'GINAL SIN, in Theology, to use the language of the English church in her ninth article, "standeth not in the following of Adam. . . but is the fault and corruption of the nature of every man that naturally is engendered of the offspring of Adam; whereby man is very far gone from original righteousness, and is of his own nature inclined to evil," and it "deserveth God's wrath and damnation." By the following of Adam is here meant the imitation of Adam; the Pelagians, against whom this article is directed, having held that the words of Scripture, "in Adam have all sinned," related not to any inherent vice in the race of Adam, but to the propensity of mankind to imitate his transgression. (August., *De Nat. et Gratiâ.*) With this exception, the original depravity of man's nature, and the consequent necessity of "a new birth unto righteousness," have been commonly held by all sects of Christians. But a great and important difference has prevailed as to the character and cause of that depravity. The belief of St. Augustine is thus expressed by Bishop Burnet:—"That a covenant was made with all mankind in Adam as their first parent; that he was a person constituted by God to represent them all; and that the covenant was made by him so that if he had obeyed all his posterity would have been happy through his obedience; but by his disobedience they were all to be esteemed to have sinned in him, his acts being imputed and transferred to them all." This doctrine of *imputed guilt* has been held by many of the stricter sects and varieties of Christians, both in and out of the church of Rome; it is said by some to be the most consonant to the words of our article, as no doubt it is to the views of the framers of it, whose sentiments were deeply tinctured with Calvinism. But it may be questioned whether those words are not as easily applicable to what is, undoubtedly, the more common opinion among Protestant Christians,—that original sin is not the sin of Adam imputed to his descendants, but is that actual depravity and tendency to evil which philosophy, no less than religion, recognizes as existing in the human mind, and developed with its growth in each individual subject; the source of which, or its permission by the Divine Author of Good, is involved in the inevitable obscurity which surrounds the great question of the origin of evil.

ORI'LLON. In Fortification, a mass of earth lined with a wall, raised on the shoulder of a bastion for the purpose of covering the retired flank.

ORI'ON. One of the forty-eight ancient constellations formed by Ptolemy. It is situated in the southern hemisphere with respect to the ecliptic, but the equinoctial passes nearly across its middle. Orion is one of the most remarkable constellations in the heavens. It contains seven stars, which are very conspicuous to the naked eye; four of them form a square, and the three others are situated in the middle of it in a straight line. Two of the four are stars of the first magnitude; namely, Rigel in the left foot, and Betelguese in the right shoulder. The three stars in the middle of the square are of the second magnitude, and form what is called the *belt of Orion*. They are also popularly called *Jacob's staff*, and the *Yard-wand*. This constellation is represented by the figure of a man with a sword by his side. The name Orion is of great antiquity, and occurs in the books of Job, Amos, and Isaiah. Orion contains a remarkable nebula, and thousands of small stars which are only visible in powerful telescopes.

Orion. In Greek Mythology, the son of Hyrieus; according to Homer, a youth slain by Diana, on account of the love borne to him by Aurora; but according to others, a king and a mighty hunter. Antiquity is full of contradictions respecting the origin, character, and fate of this mythological personage, and the only point in which it agrees respecting him is his elevation to the stars after his death. Those who wish to see all the circumstances of his history philosophically investigated should consult the dissertation of the late Prof. Müller of Gottingen, *Über Orion*, which appeared in the *Rhein. Mus. Philol.* ii. 12.

ORISMO'LOGY. (Gr. *ορισμος*, *a term*, and *λογος*, *a discourse.*) That branch of natural history which relates to the explanation of the technical terms of the science. It is also called Glossology and Terminology.

O'RLO. (Ital. *a hem or edge.*) In Architecture, the plinth to the base of a column or a pedestal.

O'RLOP DECK. The lowest deck, or rather partial deck of a ship, below the water, on which the cables are coiled, the sails, &c. stowed.

ORMOLU. (Fr.) Bronze or copper gilt usually goes under this name. The French are celebrated in this branch of manufacture.

O'RNAMENT. (Lat. ornamentum.) In the Fine Arts. *See* Decoration.

ORNITHI'CNITES. (Gr. *ορνις*, *a bird*, *ιχνος*, *a trace.*) The footmarks of birds which occur in different strata. Some of these are very remarkable, as proving the existence of birds at very remote periods; for instance, at the early epoch of the new red sandstone formation. An account of these, as occurring in the red sandstone of Connecticut, is given by Professor Hitchcock in the *American Journal of Science and the Arts.*

ORNI'THOLITES. (Gr. *ορνις*, and *λιθος*, *a stone.*) The name given to fossil birds.

ORNITHO'LOGY. (Gr. *ορνις*, *a bird*, and *λογος*, *a description.*) The science which teaches the natural history and arrangement of birds. (*See* Aves for the general organical characters of the class, and the modifications of the feet by which the five orders of the Quinary arrangement are characterized.)

The subdivision of the class of birds is by no means so clearly indicated by either external or anatomical characters as that of Mammals, and the systems of Ornithology present, in consequence, greater discrepancy than the Mammalogical ones. It is not without interest to observe that if conditions of the procreative function be taken as guides to the primary division of the class, such division will present the binary character, as in the class of Mammals and of Reptiles; for example, birds may be divided into two great groups, in one of which the young are able to run about or swim and provide food for themselves the moment they quit the shell; while in the other the young are excluded feeble, naked, blind, and dependent on their parents for support. The species comprised in the first of these groups have been termed *Aves præcoces;* those of the second *Aves altrices*.

Professor Nitzsch divided the feathered tribes into three grand primary groups, corresponding with the three great divisions of the matter of our planet, as air, earth, and water, which constitute respectively the principal theatres of their vital actions.

This first order consists of the Raptorial and Passerine birds, the birds of flight *par excellence*, which he accordingly terms "Luft-vögeln," or *Aves aereæ*. The second order embraces the birds of the earth, "Erd-vogeln," *Aves terrestres*, represented by the ostrich and common fowl. The third great division includes the birds which frequent the waters, *Aves aquaticæ* (Wasser-vögeln), typified by the heron and the gull.

Sandewall's ornithological system has four primary groups or cohorts.

In the Quinary arrangement of birds proposed by Mr. Vigors, there may be traced a similar principle to that which guided Nitzsch in his ternary classification. Thus, the first order (*Raptores*, Virg.) includes the birds which soar in the upper regions of the air, which build their nests and rear their young on the highest rocks and loftiest trees. The second order (*Insessores*) includes the birds which affect the lower regions of the air, and which are peculiarly arboreal in their habits; whence the name of Perchers. The third order corresponds with Nitzsch's *Aves terrestres*, and is termed, as in the system of Illiger, *Rasores*. If the aquatic birds of Nitzsch be divided into those which frequent the fresh waters, and are restricted to wading into rivers, lakes, &c. in search of their food, and those which have the power of swimming or diving, and for the most part frequent the great ocean, we shall then have the two remaining orders of the Quinary arrangement, viz. *Grallatores* and *Natatores*. The chief merit of this arrangement is its aim to express the natural affinities, and their circular progression in the whole and in the several parts.

Linnæus and Cuvier have six orders of birds, which are characterized as follows by the latter naturalist:—

"Of all classes of animals, that of birds is the most strongly characterized,—that in which the species bear the greatest mutual resemblance, and which is separated from all others by the widest interval. Their systematic arrangement is based, as in the Mammalia, on the organs of manducation, or the beak, and in those of prehension, which are again the beak, and more particularly the feet.

"One is first struck by the character of *webbed feet*, or those wherein the toes are connected by membranes that distinguish all *swimming birds*. The backward position of their feet, the elongation of the sternum, the neck, often longer than the legs, to enable them to reach below them, the close glossy plumage impervious to water,

altogether concur with the feet to make good navigators of the *Palmipedes.*

"In other birds, which have also most frequently some small web to their feet, at least between the two external toes, we observe elevated tarsi; legs denuded of feathers above the heel-joint; a slender shape; in fine, all the requisites for wading in shallow waters in search of nourishment. Such, in fact, is the source of food of the greater number; and although some of them resort exclusively to dry places, they are nevertheless termed 'shore-birds' or 'waders' (*Grallæ*).

"Amongst the true land birds, the *Gallinaceæ* have, like our domestic cock, a heavy carriage, a short flight, the beak moderate, its upper mandible vaulted, the nostrils partly covered by a soft and tumid scale, and always the edges of the toes indented, with short membranes between the bases of those in front. They subsist chiefly on grain.

"Birds of prey (*Accipitres*) have a crooked beak, with its point sharp and curving downward, and the nostrils pierced in a membrane that invests its base: their feet are armed with strong talons. They live on flesh and pursue other birds; their flight accordingly is mostly powerful. The greater number still retain a slight web betwixt their external toes.

"The Passerine birds (*Passeres*) comprise many more species than all the other families; but their organization presents so many analogies that they cannot be separated, although they vary much in size and strength.

"Finally, the name of Climbers (*Scansores*) is applied to those birds in which the external toe is directed backwards like the thumb, because the greater number of them avail themselves of a conformation so favourable for a vertical position to climb the trunks of trees."

Anterior to Cuvier, but subsequently in the order of publication, is Pallas's modification of the ornithological system of Linnæus. It is contained in his great posthumous work, entitled *Zoographia Rosso-Asiatica.* He also divides the class of birds into six orders:—

1. *Præpetes*, having the characters of the *Accipitres*, with which it is synonymous.
2. *Oscines*, including the genus *Columba*, with the *Picæ* and certain *Passeres* of Linnæus.
3. *Fringillæ*, corresponding with the *Crassirostres*, *Granivoræ*, *Enucleatrices* of Ray.
4. *Pulveratrices*, having the characters of the *Gallinæ*.
5. *Grallæ*. This order commences with the genus *Otis*, and includes, as in the system of Cuvier, the Struthious birds with the true waders.
6. *Hydrophilæ*. The characters of this order corresponds with that of the *Palmipedes*, with which it is equivalent. As an example of the views entertained and expressed by Pallas of relations of analogy, the following passage may be taken from his exposition of the nature of his *Hydrophilæ*:—"*Rostra* in hoc ordine admodum variant, ut nullus ordinis character inde desumi possit, et quasi reliquos ordines æmulari videntur ut *Diomedeæ* et *Catarractæ*, Rapaces, *Lari*, *Sternæ*, *Alçæ*, *Cepphi*, et *Colymbi*, Oscines; *Uriæ*, *Pulveratrices*, *Lundæ*, Passeres, et tandem *Serratirostria genera* Phœnicopterum et Plataleam inter *Grallas* referant."

The primary division of the class of birds adopted by the author of the article "Aves," in the *Cyclopedia of Anatomy and Physiology*, includes seven orders; the Struthious birds, by virtue of their remarkable anatomical peculiarities, being separated from the *Grallæ* of Linnæus and Cuvier. The following are the orders:—

1. Raptores, *Accipitres*, Linn. Cuv. Birds of prey.
2. Insessores, *Passeres*, Cuv. Perchers.
3. Scansores, Cuv. Climbers.
4. Rasores, *Gallinæ*. Linn. Cuv. Scratchers.
5. Cursores, Illig. Coursers.
6. Grallatores, *Grallæ*, Linn. Waders.
7. Natatores, *Palmipedes*, Cuv.; *Anseres*, Linn. Swimmers.

Scopoli and Latham have divided birds into *nine* orders; Temminck has *sixteen* orders; Brisson has *twenty-eight*, and Lacepede has *thirty-eight* orders; but the principles and the characters on which a classification of birds is most philosophically founded, appear to be sufficiently illustrated in the systems that have been already explained.

ORNI'THOMANCY. (Gr. ορνις, μαντεια, *divination.*) Divination by the flight of birds. The Etruscans were the most celebrated practisers of it. *See* Augurs.

ORNI'THORHY'NCHUS. (Gr. ορνις, ρυγχος, *a beak.*) The name of the genus of Monotrematous Mammals, characterized by the form of the mouth, which resembles the bill of a duck. It is peculiar to the fresh-water rivers and lakes of Australia and Van Diemen's Land.

OROMA'SDES. In Persian Mythology, the principle of Good, created by the will of the great eternal spirit Zeruane Akherene, simultaneously with Ahriman, the principle of Evil, with whom he is in perpetual conflict. Oromasdes is the creator of the earth, sun, moon, and stars, to which he originally assigned each its proper place, and whose various movements he continues to regulate. According to the Persian myths, the world, which is to last 12,000 years, during which the war between the Good and Evil Principle is to go on increasing, is at length to be consumed, the Evil Principle exterminated, and a new world created in its room, over which Oromasdes is to reign as the sole and supreme monarch. The great apostle of the Persians, Zoroaster, was the prophet of Oromasdes; and there is an old prophecy extant that after the lapse of ages a descendant of Zoroaster shall be sent by Oromasdes to redeem the world. Here we cannot fail to perceive how striking a resemblance exists between the old Persian myth and that grand scheme of redemption communicated by the Almighty to the Jews, and which was consummated by the advent of Jesus Christ. *See* Ahriman, Polytheism.

O'RPHEAN MYSTERIES. The mysteries of which Orpheus was the founder were so called. These mysteries were at a remote period in the highest estimation, and exercised an important influence over the intellectual development of mankind. Orpheus is said to have been taught his mysteries by the Idæan Dactyli; and to have introduced them into Thrace, whence they were gradually propagated throughout all Greece by his initiated followers. The nature of these mysteries is involved in an impenetrable veil of obscurity; but there can be no doubt that they partook of the general character of all mysteries, inculcating a purer knowledge of religion than was compatible with the superstitious observances then prevalent. On the union of these mysteries with the Bacchanalian orgies they fell into merited contempt, and were at length gradually disused. (*See* Mysteries.) The initiated in these mysteries, as well as the persons employed to initiate candidates in them, were called, in some cases, *Orpheotelestæ.*)

O'RPHEUS. A mythological personage; according to the common story, a son of the Thracian river Æagrus and the muse Calliope. His power of moving inanimate things by music, the share he bore in the Argonautic expedition, his descent into the Shades to recover his wife Eurydice, and his death by the violence of the Thracian women, are well-known circumstances in ancient romantic fable. Moderns have imagined that his name is a general mythic designation for the earliest bards, who came with their art from Thrace to Greece. Whether any fragments of poetry, either of the real Orpheus or of this supposed school, existed in Grecian classical ages, has been doubted. What passed as the poetry of Orpheus in the time of Aristotle seems to have been decidedly supposititious, as much so as the poems which we possess under the same name, some of which are thought to be as recent as the 4th century after Christ. According to modern theories, the Orphic poetry of ancient times contained the whole body of Grecian esoterical religion and import of the Mysteries. (See *Lobeck's Aglaophamus*; *Bode's Orpheus*; Tiedemann, *Initia Philosophiæ Græcæ*; *the History of the Literature of Greece*, Lib. U. K. p. 231.; *Mém. de l'Acad. des Sciences*, vol. xii.)

O'RPIMENT. (Lat. auripigmentum.) Yellow *sulphuret of arsenic*; it forms the basis of the yellow paint, called *king's yellow*. The solution of orpiment in ammonia has been used as a yellow dye.

O'RPIN. (Fr.) In Painting, a yellow colour of various degrees of intensity, approaching also to red.

O'RPINE. The English name for the succulent herbaceous plant called by botanists *Sedum telephium*, which see.

O'RRERY. A machine for representing to children the motions and relative magnitudes and distances of the bodies composing the solar system. As these machines are often procured by well-meaning but ignorant people at considerable expense, it may be useful to quote an authority that will not be called in question. "As to getting correct notions on this subject" (the magnitudes and distances of the planets), says Sir John Herschel, "by drawing circles on paper, or, still worse, from those very childish toys called orreries, it is out of the question." (*Astronomy, Cab. Cyc.* p. 287. For the description of an orrery see *Ferguson's Astronomy*, by Brewster.)

O'RRIS ROOT. The root of the *Iris Florentina*. It has an agreeable odour, much like violets, and is sometimes used in perfumed powders; it is also turned into little balls for issues, called *orris peas*.

O'RTHITE. (Gr. ορθος, *straight.*) A mineral which occurs in straight rays or layers in Scandinavian granite. It contains cerium and yttria.

ORTHO'CERATES, *Orthocerata*. (Gr. ορθος, and κερας, *a horn.*) The name of a family of Cephalopods with chambered siphoniferous shells, which are straight, or are continued straight after commencing with a greater or less curvature, thus resembling a horn.

O'RTHODOX, or ORTHODOXY. (Gr. ορθος, and δοξα, *opinion.*) These terms are restricted in application to right judgments in matters of religious faith; and al-

though every sect maintains of course the exclusive correctness of its own views, yet the title of orthodoxy is appropriated by ecclesiastical historians to the standard maintained by the Catholic or universal church. The term orthodox is generally restricted also to those principal tenets which have been always held by the great mass of professing Christians: large bodies of dissenters in England are allowed by the church to be orthodox, inasmuch as they hold the three creeds, and therefore profess the principal articles of the Christian faith in common with those who differ from them in matters of church authority and discipline.

ORTHODRO'MICS (Gr. ορθος, and δρομος, *course*), in Navigation, is sailing on a right course, or on the arc of a great circle, which is the shortest distance between two points on the sphere.

O'RTHOEPY (Gr. ορθος, and επος, *a word*), in Grammar, signifies literally the right use of words; but it is applied, at least by modern writers, to signify that part of prosody which treats of the manner of uttering words, or of pronunciation in its limited sense. *See* PRONUNCIATION.

ORTHO'GONAL. (Gr. ορθος, and γωνια, *angle*.) In Geometry, the same as rectangular or right-angled.

ORTHOGRA'PHIC PROJECTION. The projection of points on a plane by straight lines at right angles to the plane. *See* PROJECTION.

ORTHO'GRAPHY. (Gr. ορθος, and γραφω, *I write*.) That part of grammar which relates to the method of denoting sounds by visible signs, to the different kinds of letters, and their combination into syllables and words.

ORTHOGRAPHY. In Architecture, a geometrical representation of an elevation or section of a building.

O'RTHOPNŒ'A. (Gr. ορθος, and πνοη, *breathing*.) A difficulty of breathing, which is increased by any deviation from the erect posture.

ORTHO'PTERANS, *Orthoptera*. (Gr. ορθος, and πτερον, *a wing*.) An order of insects, including all those species which have the wings disposed when at rest in straight longitudinal folds. Latreille characterizes the insects of this order as having the body generally less firm in texture than in the Coleoptera, and covered by soft semi-membranous elytra furnished with nervures, which, in the greater number, do not join at the suture in a straight line. Their wings are folded longitudinally, most frequently in the manner of a fan, and divided by membranous nervures running in the same direction. The maxillæ are always terminated by a dentated and horny piece covered with a *galea*, an appendage corresponding to the exterior division of the maxillæ of the Coleoptera. They have also a sort of tongue.

The *Orthoptera* undergo a semi-metamorphosis, of which all the mutations are reduced to the growth and development of the elytra and wings, that are always visible in a rudimental state in the nymph. As both this nymph, or semi-nymph, and the larva are otherwise similar to the perfect insect, they walk and feed in the same way.

The mouth of the *Orthoptera* consists of a labrum, two mandibles, as many maxillæ, and four palpi: those of the jaws always have five joints; whilst the labial palpi, as in the Coleoptera, present but three. The mandibles are always very strong and corneous, and the ligula is constantly divided into two or four thongs. The form of the antennæ varies less than in the Coleoptera, but they are usually composed of a greater number of joints. Several, besides their reticulated eyes, have two or three ocelli. The inferior surface of the first joints of the tarsi is frequently fleshy or membranous. Many females are furnished with a true perforater formed of two blades, frequently enclosed in a common envelop, by means of which they deposit their eggs. The posterior extremity of the body, in most of them, is provided with appendages.

All the known *Orthoptera*, without exception, are terrestrial, even in their two first states of existence. Some are carnivorous, or omnivorous, but the greater number feed on living plants.

O'RTIVE. (Lat. ortus, *a rising*.) In Astronomy, having reference to the rising of a star or planet; thus, *ortive amplitude*, or *eastern amplitude*, is the arc of the horizon intercepted between the point where a star rises and the east point.

O'RTOLAN. The name given in France and England to a species of *Frangillidæ* greatly esteemed for the delicacy of its flesh when in season. It is the *ortolano* of the Italians, and the *fettammer* of the Germans. The ortolan is a native of northern Africa; but in the summer and autumnal months it resorts to southern Europe, and frequently migrates to the central and even the northern parts. There are large establishments in Italy and in the south of France for feeding these birds, the flesh of which is styled by Prince Musignano *carne squisita*.

O'RUS, or HORUS. An Egyptian god, son of Isis and Osiris, according to Herodotus (ii. 144.); answering to the Greek Apollo. He frequently appears in Egyptian paintings sitting on the lap of Isis. (See *Egyptian Antiquities*, London, 1836, vol. ii.)

ORVI'ETAN. An antidote to poison, said to have been invented by a mountebank of Orvieta in Italy.

ORY'CTEROPE. (Gr. ορυσσω, *I dig*, and πους, *a foot*.) A genus of Edentate Mammals peculiar to the African continent, and provided with feet and claws well adapted for digging; from which circumstance, and the heavy shapeless form of the only known species of this genus, it is commonly called at the Cape of Good Hope the ground-hog. The principal food of the orycterope is the termite and other species of ants, which it dislodges by its strong and sharp claws, and entraps by means of a long extensible and glutinous tongue. It differs from the true ant-eaters principally in having molar teeth. The orycterope is about the size of a hog, stands low, has short hair, and is of greyish-brown colour. It has four toes before and five behind, and inhabits burrows. Its flesh is eaten.

ORYCTO'GNO'SY, or ORYCTO'LOGY. (Gr. ορυκτος, *fossil*, and λογος, *a discourse*.) The branch of zoological science which treats of fossil organic remains. These terms are sometimes used to denote those parts of mineralogy which have for their object the classification of minerals, their description, nomenclature, and arrangement.

ORY'ZA. (Arab. aruz.) The name by which rice was known to the ancient Greeks and Romans, and which has been adopted by modern botanists as the generic name of the plant yielding that invaluable grain. The genus *Oryza* belongs to the class *Hexandria*, order *Dygynia*; and has ten glumes to a single flower, and two halea nearly equal adhering to the seed. It affords many varieties, of which the most common is the *Oryza sativa*, or the English rice. This plant is raised in immense quantities in India, China, and most eastern countries; in the West Indies, Central America, and the United States; and in some of the southern countries of Europe. It, in fact, occupies the same place in most intertropical regions as wheat in the warmer parts of Europe, and oats and rye in those more to the north. Forming, as it does, the principal part of the food of the most civilized and populous eastern nations, it is more extensively consumed than any other species of grain. It is light and wholesome, but is said to contain less of the nutritive principle than wheat. When rough, or in its natural state in the husk, it is called *paddy*. There is an immense variety in the qualities of rice. That which is principally exported from Bengal has received the name of *cargo* rice. It is of a coarse reddish cast, but is sweet and large-grained, and is preferred by the natives to every other sort. It is not kiln-dried, but is parboiled in earthen pots or caldrons, partly to destroy the vegetative principle, so that it may keep better, and partly to facilitate the process of husking. Patna rice is more esteemed in Europe than any other sort of rice imported from the East. It is small-grained, rather long and wiry, and remarkably white. But the rice raised on the low marshy grounds of Carolina is unquestionably very superior to any brought from any part of India.

The produce of lands naturally or artificially irrigated is, as far as rice is concerned, from 5 to 10 times greater than that of dry land having no command of water; and hence the vast importance of irrigation in all countries where this grain is cultivated. But it is worthy of remark, that owing to the not unfrequent occurrence of severe droughts, there is a greater variation in the crops of rice than in those of any other species of grain. Those who, like the Hindoos, depend almost entirely on it for subsistence, are consequently placed in a very precarious situation. There can be no doubt that famines are at once more frequent and severe in Hindostan than in any other quarter.

A few years ago, England was principally supplied with cleaned rice from Carolina. Latterly, however, the imports of Carolina rice have been much reduced. An improved method of separating the husk, which throws out the grain clean and unbroken, has recently been practised in this country; and as the grain when in the husk is found to preserve its flavour and sweetness better during a long voyage than when shelled, large quantities are now imported rough from Bengal and the United States. Unquestionably, however, the oppressive discriminating duty of 14*s*. a cwt. on American and other foreign cleaned rice has done more than any thing else to increase the imports of rough grain; and the fact of the duty on paddy from Bengal being only 1*d*. per quarter, while that on paddy from Carolina is 2*s*. 6*d*. a bushel, sufficiently accounts for the increased imports from the former. (See *Com. Dict.*, art. "Rice.")

OSCHOPHO'RIA. A celebrated festival observed by the Athenians; for full information respecting which the reader is referred to *Plutarch's Life of Theseus*, by whom it was instituted. The name is derived from απο του φερειν τας οσχας, from carrying οσχαι, i. e. *boughs hung up with grapes*.

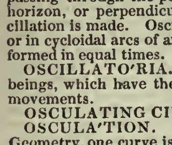
OSCILLA'TION. (Lat. oscillatio.) In Mechanics,

the vibration or alternate ascent and descent of a pendulous body. (*See* PENDULUM.) The centre of oscillation is a point in the oscillating body, such that if all the matter of the body were there collected the oscillations would be performed in the same time. (*See* CENTRE OF OSCILLATION.) The axis of oscillation is a straight line passing through the point of suspension parallel to the horizon, or perpendicular to the plane in which the oscillation is made. Oscillations in small arcs of a circle, or in cycloidal arcs of any length, are isochronal, or performed in equal times. *See* CYCLOID.

OSCILLATO'RIA. Minute filamentous organized beings, which have the faculty of exercising oscillatory movements.

OSCULATING CIRCLE. *See* OSCULATION.

OSCULA'TION. (Lat. osculare, *to embrace.*) In Geometry, one curve is said to osculate another when the two curves are in contact in such a manner that the number of points common to both is the greatest possible. Let A B be a curve, of which A C is the evolute; from P any part in A B draw P C, to touch A C in C. With C as a centre, and a radius C P, describe a circle $m\,n$; then the circle $m\,n$ osculates the curve A B at the point P. From the theory of the evolution of curve lines, the curvature of A B at the point P is equal to that of the circle; in fact, it is obvious from the development that the curvature of the involute at any point between A and P is greater than that of the circle, and at any point beyond P it is less than that of the circle, consequently at P it is exactly the same as that of the circle described with the radius C P. The circle $m\,n$ has, therefore, a more intimate contact with A B than any other circle which passes through P.



The theory of osculating curves in general is most easily explained by the methods of the differential calculus. Let $y = fx$ and $y = \mathrm{F}\,x$ be the equations of two curves; suppose x to become $x + h$, and let the functions $f(x + h)$, $\mathrm{F}\,(x + h)$, be developed by Taylor's theorem; then, if all the terms of the first development are respectively equal to the corresponding terms of the second, the curves are the same in every respect, or coincide. If the first terms only are equal, the two curves have only one common point; if the two first terms of the one development are respectively equal to the two first of the other, then two contiguous points coincide, or are common to both curves; if the three first terms in each are respectively equal, the curves have three common points, and so on. Now the number of terms of the first development which can be made equal to the corresponding terms of the second depends on the number of constants in the function fx (supposing $\mathrm{F}\,x$ to contain more constants than fx). The equations of a straight line being $y = a\,x + b$, contains two constants; the straight line can thus be made to coincide with two contiguous points of a curve: it then becomes a tangent, and the contact is said to be of the first order. The general equation of the circle is $(y - b)^2 + (x - a)^2 = r^2$, and contains three constants; a circle can therefore be determined which shall have three common points with a curve: it then *osculates* the curve, and the contact is said to be of the second order. In general, if the equation of the osculating curve is of the order n, it may have a contact of the same order with the curve which it osculates; and it is a consequence of this theory that no osculating curve of an inferior order can be made to pass between two curves having a contact of a higher order: for example, no straight line can be drawn through P between the curve A P and its osculating circle m P n. (Lagrange, *Théorie des Fonctions Analytiques;* Lacroix, *Traité du Calcul Différentiel et Intégral.*)

OSIA'NDRIANS. In Ecclesiastical History, a sect among the Lutherans; so called from their founder Osiander, a celebrated divine. They differed from the followers of Luther and Calvin as to the efficient cause of justification.

O'SIER. The name given to various species of willow or salix, chiefly employed in basket-making on account of their tough flexible shoots. (See *Loudon's Arboretum Britannicum*, p. 1490., which contains full information on all the points relative to osiers.)

OSI'RIS. In Mythology, one of the chief Egyptian divinities, the brother and husband of Isis, and together with her the greatest benefactor of Egypt; into which he introduced a knowledge of religion, laws, and the arts and sciences. After having accomplished great reformations at home, he visited the greater part of Europe and Asia, where he enlightened the minds of men by teaching them the worship of the gods and the arts of civilization; but on his return he found his own subjects excited to rebellion by his brother Typhon, by whose hand he was ultimately assassinated. Both ancient and modern writers have differed considerably respecting the powers and attributes of Osiris.* His principal office, as an Egyptian deity, was to judge the dead, and to rule over that kingdom into which the souls of the good were admitted to eternal felicity. The characters of Osiris, like those of Isis, who was thence called Myrionymus, or "with 10,000 names," were numerous. He was that attribute of the deity which signified the divine goodness; and in his most mysterious and sacred office, as an *avatar*, or manifestation of the divinity on earth, he was superior to any even of the Egyptian gods; for, as Herodotus observes, though all the Egyptians did not worship the same gods with equal reverence, the adoration paid to Osiris and Isis was universal. He was styled "the Manifester of Good;" and to this title he had an undisputed right, for he appeared on earth to benefit mankind; and after having performed the duties he had come to fulfil, and fallen a sacrifice to Typhon the evil principle (which was at length overcome by his influence after his leaving the world), he "rose again to a new life," and became the judge of mankind in a future state." Other titles of Osiris were, "President of the West," "Lord of the East," "Lord of Lords," "Eternal Ruler," "King of the Gods," &c. These, with many others, are commonly found in the hieroglyphic legends accompanying his figure; and the Papyri frequently present a list of 49 names of Osiris in the funeral rituals. Osiris has been identified with many of the Grecian divinities; but more especially with Jupiter, Pluto, and with Bacchus, on account of his reputed conquest of India. Osiris was particularly worshipped at Philae and Abydus: so sacred was the former that no one was permitted to visit it without express permission; and the latter was regarded with such veneration that persons living at a distance from it sought, and with difficulty obtained, permission to possess a sepulchre within its necropolis. The worship of Osiris was at a later period introduced into Rome; but the prurient imagination of the Romans soon converted the rites and mysteries of this deity into a means for practising the most unbounded licentiousness, which at length reached such a height that his worship was prohibited by law. Osiris was venerated under the form of the sacred bulls Apis and Mnevis; or as a human figure with a bull's head, distinguished by the name Apis-Osiris. He is usually represented as clad in pure white; and his usual attributes are the high cap of Upper Egypt, a crosier, a flagellum, and sometimes a spotted skin, an emblem supposed to connect him with the Grecian Bacchus. (For full particulars respecting the supposed history of Osiris, together with explanations thereof, we beg to refer to *Plutarch's Treatise on Isis and Osiris;* and for a resumé of the whole subject illustrated with ingenious observations, the reader may consult *Sir G. Wilkinson's Manners and Customs of the Ancient Egyptians.*) *See* ISIS.

O'SMAZOME. (Gr. *οσμη, odour*, and *ζωμος, broth.*) The extractive matter of muscular fibre, which gives the peculiar smell to boiled meat and flavour to broth and soup.

O'SMIUM. A metallic substance found associated with the ore of platinum; its peroxide is extremely volatile, and has a peculiar pungent odour, which suggested the name of the metal: from *οσμη, odour.* Neither osmium nor its compounds have been applied to any use, and it is a rare substance.

O'SSEANS, OSSEI, or PISCES OSSEI. In Ichthyology, a primary division of the class of fishes, including all those which have a true bony skeleton.

O'SSEOUS BRECCIA. The cemented mass of bone found in certain caverns and fissures of rocks.

O'SSIAN'S POEMS. The name given to a collection of poems, alleged to have been the production of Ossian, the son of Fingal, a Scottish bard, who lived in the third century. They were first given to the world in an English version by James M'Pherson, Esq., in 1760, with the assurance that they were translations made by himself from ancient Erse manuscripts which he had collected in the Highlands of Scotland; and such was the enthusiasm which their appearance excited, that they may be almost said to have given a new tone to poetry throughout all Europe. There were not, however, wanting many distinguished persons who from the first denied their authenticity: foremost among whom was Dr. Johnson, who boldly pronounced the whole of the poems ascribed to Ossian to be forgeries; and his opinion was corroborated by Hume, Gibbon, and many others, who defied M'Pherson to produce a manuscript of any Erse poem of earlier date than the sixteenth century. On the other hand, M'Pherson's assertions as to the genuineness of the poems found warm supporters in Dr. Blair (see his *Critical Dissertation on the Poems of Ossian*), Dr. Henry, Lord Kaimes, and many other distinguished names, and almost to a man in the whole body of the Highlanders. In this unsettled state the

* So cautious were those initiated into the worship of Osiris, that they made a scruple even of mentioning him; and Herodotus, wherever he relates any thing concerning this deity, excuses himself from uttering his name.

controversy remained till the year 1800, when Malcolm Laing, so well known for his historical labours, in a Dissertation appended to the second volume of his *History of Scotland*, endeavoured to establish, from historical and internal evidence, that the so called poems of Ossian are absolutely and totally spurious. The sensation created by this Dissertation was unprecedented. Many converts were made to the opinions therein set forth; but the general disbelief in the authenticity of the poems was not complete till 1805, when a committee of the Highland Society of Edinburgh, which had been appointed in 1797 to inquire into their nature and authenticity, reported to the effect "that they had not been able to obtain any one poem the same in title and tenor with the poems of Ossian." Since that period the controversy, so far as it regards their translation from Erse manuscripts, may be said to be terminated. But although these poems had never been committed to writing, or rather have not been handed down in writing, there can be, we believe, but little doubt that many of them still exist in the Highlands of Scotland in a dress not very different from that in which they were rendered by M'Pherson into English, having been committed to memory, and transmitted from one bard or storyteller to another in regular succession; and consequently their pretensions to be regarded as historical authority on many points can scarcely be denied. Their scene is sometimes laid in Scotland, but more frequently in Ireland; and they may be justly considered the *Iliad* and *Odyssey* of the Celtic race of the two islands, handed down by tradition only: — what the poems of Homer were, in all likelihood, to the Greeks themselves before they were acquainted with the art of writing. "The value of Ossian," says Mr. Skene, "as an historical poet, must stand in the highest rank; while, whether the chief part of these poems are of ancient or of modern composition, there can remain little doubt that in him we possess the oldest record of the history of a very remote age." (*The Highlanders of Scotland, their Origin, History, and Antiquities*, vol. i. p. 215.) Those who wish to see this subject exhibited in all its bearings, though, perhaps, with a slight prejudice against M'Pherson, may consult the elaborate article in the *Edin. Review*, vol. vi.

O'SSIFICATION. The formation of bone. The change of any soft solid of the body into bone.

OSTA'RA. An ancient German and Celtic divinity, worshipped with peculiar veneration by the Anglo-Saxons. Many writers regard her as identical with the Phœnician goddess Astarte; but, be this as it may, she was regarded as the queen of spring and of the morning; and from her name is derived the German *Ostern* (Anglice, *Easter*), which period of the year the ancient Germans were in the habit of celebrating with fires and festivals in gratitude for the advent of spring. (See *Grimm's Deutsche Mythologie*, p. 181.) The town Osterode on the Hartz is said to have been named from this goddess.

OS'TEOCO'LLA. (Gr. *οστεον, a bone*, and *κολλα, glue.*) An old mineralogical term for *encrusting* carbonate of lime, to which the property of uniting a fractured bone has been attributed.

OSTEO'GENY. (Gr. *οστεον, a bone*, and *γενναω, I generate.*) The formation or growth of bone.

OSTEO'LOGY. (Gr. *οστεον, a bone*, and *λογος, a discourse.*) The doctrine or history of the bones. *See* ANATOMY, BONE.

OSTEOLOGY. In Painting and Sculpture, a description of the bones of animals.

OSTRA'CEANS, *Ostracea*. The family of Bivalves of which the oyster (*Ostrea*) is the type; and which is characterized by the mantle being widely open, without special orifices.

OSTRA'CION. (Gr. *οστρακον, a shell.*) A genus of fishes of the order *Sclerodermi*, or rough-skinned, in the system of Cuvier. It is characterized by the armour of regular bony plates soldered together, with which the body is invested; the only moveable parts being the tail, fins, mouth, and a small gill-flap, which pass, as it were, through holes in the coat of mail. The body generally presents a quadrangular form, whence the name of trunk-fish, commonly given to the species of this genus.

O'STRACISM. (Gr. *οστρακισμος.*) A form of condemnation at Athens, by which persons who from their wealth or influence were considered dangerous to the state were banished for ten years, with leave to enjoy their estates and return after that period. It was not inflicted as a punishment, but merely as a precautionary measure to preserve the democracy. The process in this condemnation was as follows: — The people being assembled each man wrote the name of the person he wished to banish on a shell (*ὀστρακον*, whence the name *ὀστρακισμος*), and delivered it to the archons, who counted the numbers. Only one individual could be subjected to the ostracism at the same meeting, and 6000 hostile votes were necessary to the infliction of this condemnation. Hence if 6000 votes and upwards were recorded against one or more individuals, the one was banished against whom the greatest number of votes had been given. (See *Mem. de l'Acad. des Inscr.* vol. xvi.)

O'STRACODES, *Ostracoda*. (Gr. *οστρακον, a shell, ειδος, form.*) The name of a family of Entomostracans, comprehending those which have the shell folded in two, so as to resemble the shell of a bivalve mollusk.

O'STRICH. The largest known bird, and the type of the Cursorial or Struthious order. It is distinguished not only from its immediate congeners the *Cassowaries* and *Apteryx*, but from all other birds, by having only two toes, which correspond with the two outermost toes in the rest of the class. The wings are furnished with loose and flexible plumes, but are long enough to increase its speed in running. The elegance of these feathers, arising from their slender stems and the disunited barbs, has occasioned them to be prized in all ages, and they still constitute a valuable article of commerce. The beak of the ostrich is depressed, of a moderate length, and blunt at the end; the tongue is extremely short; the eye is large, and the lid fringed with short simple feathers like eyelashes. The legs are of prodigious strength, and the tarsi very long. The ostrich has a capacious crop; a strong gizzard; voluminous intestines, with two long cœca, complicated each with a spiral valve, and succeeded by a very long intestinum rectum with internal connivent valves, which latter structure is unique in the class of birds. It is likewise remarkable in this class for its large urinary receptacle. The ostrich abounds in the sandy deserts of Arabia and Africa. It attains the height of seven or eight feet; is gregarious in favourable localities; lays eggs of three pounds weight, which are incubated by the male principally, and defended courageously. The ostrich feeds on grain, grass, &c., to aid in digesting which many pebbles are taken into the gizzard; so obtuse is its taste that it will swallow pieces of metal, wood, &c. When pursued it dashes stones behind it with great violence, and exceeds in swiftness all other terrestrial animals; it is only the comparatively limited power of sustaining its course that enables the mounted Arab to run it down.

OTA'LGIA. (Gr. *ους, the ear*, and *αλγος, pain.*) The ear-ache.

OTA'RIA. (Gr. *ους.*) The name of the genus of seals characterized by having projecting external ears, and by the double cutting edge of the four middle upper incisors, a structure unknown in other animals: the molar teeth are simply conical, and with a single fang. These seals are principally confined to the southern hemisphere.

OTI'TIS. (Gr. *ους.*) Inflammation of any part of the organ of hearing.

O'TTAR, or OTTAR OF ROSES. The volatile or odorous oil of the rose; it is of a soft buttery consistence, and deposits when fluid a crystallizable portion, which is sparingly soluble in alcohol: it is much used as a perfume. The finest ottar of roses is prepared at Ghazedpore in India.

OTTA'VA RI'MA. (Eighth or octuple rhyme.) An Italian form of versification, consisting of stanzas of two alternate triplets and a couplet at the end; the verses being, in the proper Italian metre, the heroic of eleven syllables. It is the form peculiarly adopted and embellished by the poets termed Romanzieri, from Pulci to Fortiguerra. (*See* ROMANZIERI.) It is a happy metre, in the hands of an able versifier, for the expression of feelings varying from the sublime and pathetic to the humorous: although rather deficient in variety, and possessing too little repose and solemnity for the sustained majesty of epic poetry. It has been adopted by the Germans, who have given to it something of an elegiac turn; and, of late, by English poets, of whom the most distinguished is Lord Byron, who has employed it in his *Beppo* and *Don Juan*, works belonging to a mixed cast of poetry, between the serious and the burlesque.

O'TTER. A quadruped adapted to amphibious habits by its short, strong, flexible, palmated feet, which serve as oars to propel it through the water, and by its long and strong tail, which acts as a powerful rudder, and enables the animal to change its course with great ease and rapidity. The teeth, which consist, in each jaw, of six pointed incisors, two strong and sharp canines, and ten trenchant and cuspidated molars, determine the piscivorous diet and predatory habits of the species. The otter used to be met with in most of the British rivers and lakes; but the increase of population, and the unintermitting hostility which its destruction of the valuable fish of its native streams have called down upon it, have greatly thinned its numbers, and have exterminated it from many of the localities where it was formerly common; so that the otter, as a captive in our menageries, is now regarded with almost the same interest which an exotic species usually excites.

The otter selects for its retreat some convenient excavation concealed by the overhanging roots of the trees which grow from the banks of rivers, or other natural screen. The female goes with young nine weeks, and produces from three to five cubs in March or April. The usual weight of a full-grown male is from twenty to

twenty-four pounds. The fur of the otter is remarkably fine and close. It consists of two kinds of hair; the longer and stiffer shining hairs, which are greyish at the base and a rich brown at the point, concealing an extremely fine and soft fur of a whitish grey colour, brown at the tip. The hair and fur of the under part of the body, the cheeks, and the inner parts of the legs, is of a brownish grey throughout.

The otter is hunted in many parts of England, and especially in Wales, with dogs especially trained for this kind of sport, and with all the form and circumstance of the chase. "When the otter is found," says Mr. Bell, "the scene becomes exceedingly animated. He instantly takes the water and dives, remaining a long time underneath it, and rising at a considerable distance from the place at which he dived. Then the anxious watch that is kept of his rising to 'vent,' the steady purpose with which the dogs follow and bait him as he swims, the attempts of the cunning beast to drown his assailants by diving whilst they have fastened on him, the baying of the hounds, the cries of the hunters, and the fierce and dogged resolution with which the poor hopeless quarry holds his pursuers at bay, inflicting severe, sometimes fatal wounds, and holding on with unflinching pertinacity even to the last, must altogether form a scene as animated and exciting as the veriest epicure in hunting could desire." (*British Quadrupeds*, p. 133.)

The few species of otter which have been recognized in distant parts of the world do not greatly differ from the *Lutra vulgaris* of Europe. The sea-otter is an animal of larger size, and presents such modifications of its palmated feet, and of its teeth, as to form the type of a distinct subgenus (*Enhydras*), which connects the otter with the seal.

O'TTOMAN. An epithet given to the Turkish empire, from Othman I., who ascended the throne in the 14th century. It is also applied to a peculiar kind of sofa much in use in Turkey, and which has been imitated both here and on the Continent.

OUNCE. (Lat. uncia.) A denomination of weight. In troy weight the ounce is the 12th part of the pound, and weighs 480 grains. In avoirdupois weight the ounce is the 16th part of the pound, and equal to 437½ grains troy. *See* WEIGHT.

OURANO'GRAPHY. (Gr. ουρανος, *heaven*, and γραφω, *I describe*.) A term frequently used to signify a description of the heavens and the heavenly bodies.

OURO'LOGY, or OURO'SCOPY. (Gr. ουρον, λεγω, *I speak*, and σκοπεω, *I view*.) The judgment of diseases from an examination of the urine.

OU'TCROP. A Geological term, implying the exposure of a stratum at the earth's surface.

OU'TLAWRY, in Criminal Law, is a punishment inflicted for a contempt in refusing to be amenable to the jurisdiction of a competent court. The act 2 W. 4. c. 39. gives a provision for more expeditious and less expensive proceeding to outlawry in civil cases on mesne process than had previously prevailed. It is issued against a defendant after he has been five times proclaimed at a county court; but if the defendant has previously left the kingdom, he can set it aside by writ of error, or even on motion. The effect of outlawry in civil cases is a forfeiture of personal goods and chattels immediately upon the outlawry, and his chattels real and the profits of his lands when found on inquisition.

OU'TLIER. In Geology, a portion of a rock or stratum detached and at some distance from the principal mass.

OU'TLINE. In the Fine Arts. *See* CONTOUR.

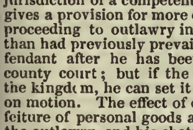
OU'TPOSTS. In a Military sense, a body of men posted beyond the main guard; so called as being the bounds or limits of the camp.

OUTRÈ. (Fr.) In the Fine Arts, anything exaggerated or overstrained.

OU'TRIGGER. The Sea term for any projecting spar or piece of timber for extending ropes, sails, or other temporary purposes.

OU'TWORKS. In Fortification, works raised on the outside of the ditch of a fortified place, for the purposes of covering the place, or keeping the besiegers at a distance. *See* FORTIFICATION.

O'VAL. (Lat. ovum, *an egg*.) A popular name for any curve figure resembling an ellipse, or the transverse section of an egg. The carpenter's oval is made up of four circular arcs, joined so as to leave no angular appearance, or present any rapid change of curvature. It may be described as follows: — Let A B and C D be the length and breadth of the proposed oval, and let these lines be placed at right angles, and bisecting each other at E. With C as a centre, and a radius equal to A E, describe an arc intersecting A B in F and G; with F and G as centres, and a radius equal to A F or B G, describe the small arcs m A m' and n B n' for the ends of the oval; and with C and D as centres (or centres near those points), and C D as a radius, describe the arcs m C n and m' D n'. It may be remarked, that the construction will fail when the breadth C D is not greater than half the length A B; but in this case C D may be produced, and points found in it by trial for the centres of the required arcs.



The *Ovals of Descartes* are a species of geometrical curves, proposed by that philosopher as the figures which give by their revolution about an axis the true surfaces which should separate two media of different densities, in order that all the rays which proceed from the same point, or converge towards one, may be refracted towards another point, or rendered parallel or divergent. They may be defined as the locus of the vertex of a triangle on a given base, one of whose sides has a given ratio to the sum or difference of a given line and the other side. Their generation has thus some resemblance to that of the ellipse and hyperbola, which are the loci of a triangle on a given base whose sides in the case of the ellipse have a given sum, and in the case of the hyperbola a given difference. (See the *Second Book of Descartes' Geometry*.)

Ovals are also produced by the construction of many equations of the higher orders, particularly those in which the dimensions are even, as the fourth, sixth, &c.

OVALBU'MEN. The albumen or white of egg; a term adopted in order to distinguish it from the albumen of the serum of the blood, which may be called *seralbumen*.

OVA'RIA. The two organs which contain the female ova.

OVA'RIUM. In Plants, a hollow case, enclosing ovules or young seeds, containing one or more cells, and ultimately becoming the fruit; it is always situated in the centre of the flower, and, together with the style and stigma, constitutes the female system of the vegetable kingdom. When it is united to the calyx, it is called inferior; when separate from it, it is termed superior.

OVA'TION. An inferior kind of triumph, which, according to the ancient Roman custom, was granted to distinguished military leaders. The name is said to be derived either from ovare (*to cry O!*), the cry of the soldiers; or from ovis, *a sheep*, the animal sacrificed on such occasions instead of bullocks. According to Dionysius of Halicarnassus, the first ovation was celebrated by P. Posthumius Tubertus (A.C. 503), some years after the expulsion of the kings. Some antiquaries imagine the distinction between the triumph and the ovation to have originally consisted, not in the greater or less degree of honour, but in the latter being strictly appropriated to successes by which peace was obtained, or to distinguish brilliant achievements in time of peace. Thus we find that ovations were permitted, though triumphs were not, in civil wars. An ovation was celebrated by Mark Antony and Octavius to solemnize their reconciliation.

OVERHANG. In Architecture. *See* BATTER.

O'VERSEERS OF THE POOR. Officers annually appointed in every parish, under the hand and seal of two justices, under the statute of 43 Eliz. Their number, by that statute, is four, three, or two, for each parish. By subsequent statutes any place maintaining its own poor, whether a parish or not, has overseers. Assistant overseers, with a salary, may be elected by the inhabitants of parishes, under 59 G. 3. *See* POOR LAWS.

O'VERSHOT WHEEL. In Mechanics, a water-wheel to which the water is conveyed over the top of the wheel and applied above the axle. In this case, the water acts merely by its weight, and not by the impulse of the stream.

O'VERT ACT. (Fr. ouvert, *open*.) In Law, an open or manifest act from whence criminality is implied. No indictment for high treason is good unless some *overt act* is alleged in it.

O'VERTURE. (Fr. ouverture.) The introductory piece of music prefixed to an opera or oratorio. Its movements in works of the modern school generally contain snatches of the more prominent and leading airs in the opera, and introduce the audience to a general notion of the emotions which it is the desire of the author to excite.

The word *overture* also signifies a *proposal*; in which sense it is always used in the Presbyterian church to indicate those resolutions proposed by presbyteries and synods, and afterwards laid before the General Assembly, either for its sanction or rejection.

O'VIDUCT, *Oviductus*. (Lat. ovum, *an egg*; duco, *I conduct*.) The tube which conducts the ovum from the ovary either to the uterus or to an external outlet. In Mammals this part is termed the Fallopian tube, from the circumstance of its having been first described by Fallopius about the year 1560 in the human subject, in which this tube or canal passes from each side of the fundus of the uterus to the ovarium. *See* FALLOPIAN TUBE.

OVI'FEROUS and OVI'GEROUS. (Lat. ovum, fero and gero, *I bear*.) In Zoology, certain receptacles, in which the eggs are received after having been excluded from the ordinary formative organs of the ovum, are so

called, as the long pouches appended to the hinder part of the body in many of the Entomostracous and Parasitic Crustaceans. Likewise the ciliated plates (beneath the tail of the higher Crustaceans, as the crab and lobster), to which the eggs are attached after having quitted the oviducts, are called ovigerous.

OVI'PAROUS. (Lat. ovum, and pario, *I produce.*) The mode of generation by the exclusion of the germ in the form and condition of an egg, the development of which takes place out of the body either with or without incubation. Fishes, reptiles, and birds are called Oviparous Vertebrata, although some of both the former classes hatch the egg within the body and bring forth their young alive, as the viper and dog-fish.

O'VIS. (Lat. *a sheep.*) The name by which Linnæus and Cuvier distinguish the sheep as a genus from the goats and antilopes. The character assigned by Cuvier to the genus *Ovis* is as follows:—"Horns directed backwards, and then inclining spirally more or less forwards; the profile or chaufrein more or less convex, and no beard:" to this may be added an interdigital sebaceous sac on the fore part of each foot. The *Mouflons* or *Musmons* of Africa and Sardinia, from which it is generally believed our domestic races of sheep are derived, form the species *Ovis ammon* of Linnæus, and *Ovis musimon* of Schreber. The coat of these wild sheep consists of coarse, stiff, long, and nearly straight hairs; but they possess the same character, that of an imbricated surface, which gives to the shorter and finer wool of the domestic races the felting property on which its peculiar utility depends. *See* HAIR.

Of the domestic animals belonging to Great Britain sheep are, with the exception perhaps of horses and cattle, by far the most important. They can be reared in situations and upon soils where other animals would not live. They afford a large supply of food, and one of the principal materials of clothing. Wool has long been a staple commodity of this country, and its manufacture employs an immense number of people. "The skin, dressed, forms different parts of our apparel; and is used for covers of books. The entrails, properly prepared and twisted, serve for strings for various musical instruments. The bones, calcined (like other bones in general), form materials for tests for the refiner. The milk is thicker than that of cows, and consequently yields a greater quantity of butter and cheese; and, in some places, is so rich that it will not produce the cheese without a mixture of water to make it part from the whey. The dung is a remarkably rich manure; insomuch that the folding of sheep is become too useful a branch of husbandry for the farmer to neglect. To conclude, whether we consider the advantages that result from this animal to individuals in particular, or to these kingdoms in general, we may, with Columella, consider this, in one sense, as the first of the domestic quadrupeds. '*Post majores quadrupedes ovilli pecoris secunda ratio est; quæ prima sit si ad utilitatis magnitudinem referas. Nam id præcipue contra frigoris violentiam protegit, corporibusque nostris liberaliora præbet velamina; et etiam elegantium mensas jucundis et numerosis dapibus exornat.*'—(*De Re Rustica*, lib. vii. cap. 2.) And, in addition to what Mr. Pennant has so forcibly stated, sheep are particularly deserving the attention of the agriculturist, both from the influence of improvements on the breed, and from their generally affording larger profits than can be obtained from the rearing and feeding of cattle. (*Statistics of the Brit. Empire*, vol. i. p. 492.)

The principal varieties of the English sheep are the large Lincolnshire, the Dorset breed, the South-down, and the Cheviot.

The Lincolnshire sheep are of a large size, big-boned, and afford a great quantity of wool, owing to the rich marshes on which they feed; but their flesh is coarser, leaner, and less finely flavoured than that of the smaller breeds.

The Dorset sheep are mostly white-faced; their horns are finely curved, their fleece clear and white; but many of them are without wool upon their bellies; their legs are long and small, and their general form handsome and well-proportioned. This breed is prolific, and is principally esteemed for producing lambs at an earlier period than other varieties. "Great numbers of these premature victims to luxury are yearly sent to the London markets, where they fetch the price of 10*s*. 6*d*. to 15*s*. per quarter. The manner of rearing the lambs is curious: they are imprisoned in little dark cabins; the ewes are fed on oil-cakes, hay, corn, turnips, or cabbages, which are given them in a field contiguous to the apartments where the lambs are kept; and at proper intervals the nurses are brought in to give suck to their young ones, while the attendants at the same time make their lodgings perfectly clean, and litter them with fresh straw. Great attention is paid to this, as much of the success of rearing these unseasonable productions depends upon warmth and cleanliness."

The South-down sheep have dun or black faces, and are of the same hardy nature as the Cheviot breed, being able to live and thrive on the barest chalk hills. Their wool is fine and their mutton well-flavoured. They have of late years, in consequence of these valuable qualities, extended to most parts of England, and have been introduced into Ireland. The Cheviot breed have no horns, and are mostly white-faced and white-legged; the body is long, with fine, clean, small-boned legs: the mutton is highly esteemed for its flavour. They are valuable as mountain sheep, on account of their hardiness and the superior value of their wool. There is a singular variety of sheep in the northern climates of Europe, in which the monstrosity of supernumerary horns has become hereditary: these are called many-horned sheep, and have from four to eight horns growing irregularly from the head.

It is not possible to form any accurate estimate either of the number of sheep or of the quantity of wool annually produced in this country. With the exception of Mr. Luccock's, most of the statements put forth with respect to both these points seem very much exaggerated. But Mr. L.'s estimate, which is considerably under any that had previously appeared, was drawn up with great care, and is supposed to approach nearer to accuracy.

According to Mr. Luccock, the

Number of long-woolled sheep in England and Wales, in 1800, was	4,153,308	
Of short-woolled, ditto -	14,854,299	
Total number shorn -		19,007,607
Slaughter of short-woolled sheep per annum - -	4,221,748	
Carrion of ditto - - -	211,087	
Slaughter of long-woolled ditto -	1,180,413	
Carrion of ditto - - -	59,020	
Slaughter of lambs - - -	1,400,560	
Carrion of ditto - - -	70,028	
		7,140,856
Total number of sheep and lambs -		26,148,463

In some parts of England there has been an increase in the numbers of sheep since 1800; but in others there has been a decrease. But we have been assured by competent judges that, on the whole, the number has not sensibly varied in the interval.

In the *General Report of Scotland* (vol. iii. Appendix, p. 6.) the number of sheep is estimated at 2,850,000; and, allowing for the increase that has taken place since 1814, they may now be estimated at about 3,500,000. Hence the total number of sheep in Great Britain will be 39,648,000. It is not supposed that there are 2,000,000 of sheep in Ireland. (*Statistics of the British Empire*, vol. i. p. 496.)

The foreign breeds of sheep are exceedingly numerous; but of these, perhaps, the Asiatic variety is the most singular. In India, the sheep is long-tailed; and in Persia, Tartary, and China, &c., the tail is not only elongated, but loaded with a mass of fat in some instances weighing ten pounds. The power which this animal possesses to accommodate itself to different climates seems almost unlimited: in the hot plains of Asia its covering becomes coarse and scanty; while in the frozen regions of Thibet its thick wool has an under lining of the finest kind, forming an important article in manufactures and commerce. (See the *Geo. Dict.*, art. "Asia," and the authorities there cited.)

O'VISAC, *Ovisaccus*. (Lat. ovum, *an egg*, and saccus, *a sack.*) The cavity in the ovary which immediately contains the ovum. In Mammals it forms, after the ovum is expelled, the *corpus luteum*.

OVIPO'SITOR (Lat. ovum, and pono, *I place*), in Entomology, is the instrument by which an insect conducts its eggs to their appropriate nidus, and often bores a way to it; the same instrument is, in some genera, used as a weapon of offence, when it is called the "aculeus."

O'VOLO. (Ital.) In Architecture, a moulding whose profile is the quadrant of a circle; though in Grecian architecture there is a deviation from that exact form, which is most apparent at the upper portion, where it resembles the form of an egg, whence this moulding derives its name.

OVOVIVI'PAROUS. (Lat. ovum, *an egg;* vivo, *I live;* and pario, *I produce.*) The mode of generation by the exclusion of a living fœtus more or less extricated from the egg-coverings, which has been developed within the body of the parent without any vascular or placental adhesions between the ovum and the womb. The marsupial animals among the Mammalia, the viper and salamander among Reptiles, the blenny and dog-fish among fishes, the *Paludina vivipara* and many bivalves among Mollusks, the scorpion and flesh-fly among insects, the earth-worm, and many of the intestinal worms, are examples of oviviparous animals.

O'VULUM. (Lat. ovum, *an egg.*) The name of a genus of Pectinibranchiate Gastropods, characterized by having a shell of an oval form, and with a long and narrow aperture, without furrows or teeth, on the side of the columella; the spire is concealed, and the two extremities of the aperture are equally prolonged into a canal.

This diminutive is also applied to the ovum of the Mammalia on account of its relatively minute size: it is, however, a true ovum, having all the essential parts, as the germinal spot, germinal membrane, vitellus, vitelline membrane, and chorion. *See* OVUM.

OVULUM. In Botany, a small pellucid pulpy body, borne by the placenta of a plant, and gradually changing into a seed; it consists of a central nucleus, enclosed within a definite number of coats, varying from one to two, and furnished with an aperture or foramen, through which impregnation takes place.

OVUM. (Lat. *an egg.*) In Anatomy, the body formed by the female in which, after impregnation, the development of the fœtus takes place. It is generally formed in a special organ, called the ovarium; but in some of the simplest animals, as the Polypes, the common cellular parenchyme of the body seems to have the unlimited faculty of producing the ova. The essential and apparently first-formed part of an ovum is a minute pellucid cell, called the "germinal vesicle," which is characterized by an opaque speck or nucleus, called the "germinal spot." The vesicle is immediately surrounded by a stratum of granules or nucleated cells, which form the "germinal disk." These parts float in a greater or less quantity of fluid and granules, called the yolk, which is generally of some well-marked colour, as yellow, green, violet, red, through the presence of a minutely diffused oil. The yolk is inclosed in a thin, delicate, structureless coat, called the "vitelline membrane," and this is finally surrounded by an outer tunic called the "chorion." Between the chorion and vitelline membrane there is commonly a greater or less quantity of albumen. In the birds this fluid, which is called the "white," and the "yolk," is in great quantity; the chorion is laminated, and the outer layer is combined with earthy salts to give due firmness, and preserve the shape of the egg while subject to the weight of the parent during incubation. Two twisted strings of firm albumen, called "chalazæ," are continued from each end of the yolk, a little below the poles, and serve to keep uppermost the "cicatricula" or "tread," formed by the impregnated germinal vesicle and disk. A space intercepted between two of the layers of the chorion, or "membrana putaminis," at the great end of the egg, contains a small quantity of gas, containing more oxygen than atmospheric air: this space is called the "vesica aerea." (For the chemical properties of *ovum*, see EGG.)

OVUM. In Architecture, the same as Ovolo; which see.

OWL. *See* NOCTURNALS and STRIX.

OW'LING. In Law, so called from its being generally committed during the night. An offence consisting in conveying sheep or wool to the sea side in order to export them. This offence was formerly capital, particularly if the offenders neglected to surrender after proclamation made for that purpose; — it is now punishable with seven years' banishment.

OWL, THE. Among the ancients, generally was considered as an omen of misfortune or death. As, however, according to Philostratus, the Egyptians represented Minerva under the form of an owl, the Athenians, so peculiarly under the care of this goddess, looked upon the appearance of this bird as a favourable omen. From this circumstance it formed, upon ancient coins, the symbol of Athens and her foreign possessions.

OX. Synonymous with the generic name *Bos*, which see; in a more restricted sense it signifies the castrated male of the domestic variety.

OXALAMIDE. *See* OXAMIDE.

O'XALATES. Salts of the oxalic acid.

OXA'LIC ACID. A vegetable acid, first discovered in the juice of the *Oxalis acetosella;* it was afterwards ascertained that the same acid might be produced artificially by the action of nitric acid upon sugar: this process yields it in slender prismatic crystals, intensely sour, and soluble in about 10 parts of cold water. These crystals consist of 1 atom of real acid and 3 of water: the equivalent of the acid is 36; and in its anhydrous state, as it exists in the dry oxalates, it is constituted of 2 atoms of carbon $(6 \times 2) = 12$, and 3 of oxygen $(8 \times 3) = 24$: so that it may be represented by an atom of carbonic acid and one of carbonic oxide. Solutions of oxalic acid, or of soluble oxalates, yield an insoluble precipitate in solutions containing lime and its salts: hence its use in the laboratory as a test of the presence of that earth. The solution of oxalate of ammonia is generally used for the purpose. Oxalic acid is a powerful poison, and, from its resemblance to Epsom salt, it has sometimes been sold and mistaken for that harmless aperient. In such cases, the best antidote is a mixture of chalk and water, and where it is immediately administered it generally prevents the accession of fatal symptoms; it forms an insoluble oxalate of lime, which is inert.

OXALIDA'CEÆ. (Oxalis, one of the genera.) A natural order of herbaceous or shrubby Exogens, inhabiting the hotter and temperate parts of the world. Their foliage is generally acid, and fit to supply the place of sorrel. *Oxalis acetosella* contains pure oxalic acid, and many are used in Brazil against malignant fevers.

O'XAMIDE. A white substance produced during the destructive distillation of oxalate of ammonia: hence its name, compounded of *oxalis* and *ammonia*. It is a compound of nitrogen, hydrogen, oxygen, and carbon, in such proportions as to form oxalate of ammonia by the addition of one atom of water. (See Dumas, *Theorie des Amides, Chim. App. aux Arts*, v. 84.)

OXGANG (Germ. ochs, *an ox*, and gang, *a walk*), in English Antiquities, was used to signify as much land as a single ox could *ear* or plough in a season. The *oxgang* was contracted or expanded according to the quality of the land; forty acres constituting the *maximum* and six the *minimum* of the measure.

OXIDATION, or OXIDIZEMENT. The act of combination with oxygen.

O'XIDE. (Gr. *οξυς*, *acid*, and *ειδος*, *form.*) Compounds containing oxygen, but which are not *acid*, have been termed *oxides*. The metallic oxides are a most important class of bodies. To designate the different oxides of one base we generally use the first syllable of the Greek ordinal numerals, designating the first, second, third, &c. oxides by the terms *protoxide, deutoxide, tritoxide,* &c.; and when the base is saturated with oxygen (still not acid), it is termed a *peroxide*. Compounds of bases with one atom and a half oxygen, or of two base and three oxygen, are now generally distinguished by the term *sesquioxides*.

O'XYGEN. (Gr. *οξυς*, and *γενναειν*, *to generate.*) This important element was discovered, in 1774, by Dr. Priestley. It has been termed *dephlogisticated air, vital air*, and *empyreal air*. As it forms a component part of many of the acids, it was termed, at the framing of the new nomenclature, *oxygen gas*. There are several compounds of oxygen which, when exposed to heat, are decomposed, and yield the gas in a state of purity: of these the best is chlorate of potash; but as that salt is expensive, we generally resort to black oxide of manganese, which, at a dull red heat, gives out a considerable quantity of tolerably pure oxygen gas.

Oxygen gas is colourless, tasteless, and inodorous; it is electro-negative, and therefore when compounds containing it are electrically decomposed, it always appears at the positive surface. It is a little heavier than atmospheric air, in the proportion, that is, of 11 to 10; 100 cubical inches weighing 34·6 grains. It is not absorbed by water, and is neither acid nor alkaline. It has a powerful attraction for most of the simple substances, especially for the electro-positive bodies: the act of combining with it is called *oxidation*. The compounds thus formed are divided into *acids* and *oxides:* among the latter are the alkalis, and almost all salifiable bases. Oxidation is often attended with the evolution of heat and light, as in all processes of combustion in atmospheric air: sometimes it is slow, and unattended with such phenomena, as in the gradual rusting of metals. Oxygen is a most powerful supporter of combustion; it constitutes one fifth of the bulk of the atmosphere, and is the principle which enables combustible bodies to burn in it. The product of combustion, that is, the oxide or acid, is sometimes itself gaseous, as when charcoal, by burning, is converted into carbonic acid; or it is liquid, as hydrogen, by combustion, produces water; or it is solid, as when iron, by burning, produces oxide of iron. Oxygen gas is also essential to respiration; that is, to the evolution of carbonic acid from the blood.

OXY'GONE. (Gr. *οξυς*, and *γωνια*, *angle.*) In Geometry, a term applied to figures in which all the angles are acute.

OXYHY'DROGEN BLOWPIPE. When a mixture of one volume of oxygen and two of hydrogen are burned whilst issuing from a small aperture, they produce intense heat; and instruments under the above name have been contrived for their safe combustion, so as to avoid the risk of explosion.

O'XYMEL. (Gr. *οξυς*, and *μελι*, *honey.*) A mixture of honey and vinegar. It is sometimes made the vehicle of medicines, as oxymel of squills, &c.

OXYMU'RIATE OF LIME. The valuable bleaching compound obtained by exposing slaked quicklime to the action of chlorine is commonly so termed; it is, however, a chloride of lime.

O'XYMURIA'TIC ACID. This name was originally applied to chlorine, under the idea that it consisted of muriatic acid and oxygen. The fallacy of that opinion was first demonstrated by Davy, who showed that, in all the apparent cases of the evolution of oxygen from chlorine, its source was referable to the presence of water or of an oxide. Chlorine possesses a stronger attraction for bases than oxygen; so that, when metallic oxides are exposed to its action, the chlorine combines with the metal to form a chloride (formerly called a *muriate*), and the oxygen is evolved.

OXYO'PIA. (Gr. *οξυς*, and *ωψ*, *the eye.*) Preternaturally acute vision.

OXYU'RES, *Oxyuri.* (Gr. *οξυς*, and *ουρα*, *a tail.*) The

name of a family of Pupivorous Hymenopterans, comprehending those which have a sort of tail, or terminal appendage, produced by an external ovipositor or borer. A genus of intestinal worms (Cæleiminthans) is also called *Oxyurus*.

OYER. (From the Norman French oyer, *to hear.*) In Law, when an action is brought on a bond or other specialty the defendant, previously to pleading in bar, may crave oyer of the instrument on which the action is brought; that is, to have it read to him; which prayer includes that of a copy also. Whenever offer of a deed is necessarily made by the party relying on it (by what is termed a *profert in curia*), the other party may crave oyer. Oyer is not, in strictness, demandable of a record, or of an act of parliament.

OYER AND TERMINER. (Fr. *to hear and determine.*) In Law, a commission directed to the judges, and other gentlemen of the courts to which it is issued, by virtue of which they have power, as the terms imply, *to hear and determine* certain specified offences.

OYEZ. (Plur. imperative of the same verb.) "Hear ye." The cry of ushers in Norman courts of justice, metamorphosed into the English "O yes."

OYSANITE. *See* OISANITE.

OYSTER. (Lat. ostrea, *an oyster.*) This name is generally understood to signify the species of Ostracean bivalve called *Ostrea edulis*, which is one of a numerous genus, characterized by an inequivalve shell, composed of two irregular lamellated valves, of which the convex or under one adheres to rocks, piles, or to the shell of another individual. The animal is unprovided with either a byssus or a foot; it is the best flavoured of its class, and has, consequently, been always much esteemed. Vast beds of oysters are artificially formed, and attended too with great care, at the estuary of the Thames and many other localities, where the temperature of the water is somewhat raised by a mixture of salt and fresh water, in which they best thrive. Certain restrictions and regulations are enforced in reference to the sale of oysters in the metropolis, in order to favour the multiplication and rearing of this valuable bivalve. They are permitted to be sold from August to May, the close months being May, June, and July. They cast their spat or spawn in May, when they are said to be sick; but begin to recover in June and July, and in August they are perfectly well. Oysters differ in quality, according to the different nature of the soil or bed. The best British oysters are found at Purfleet; the worst near Liverpool. The nursing and feeding of oysters is almost exclusively carried on at Colchester, and other places in Essex. The oysters are brought from the coast of Hampshire, Dorset, and other maritime counties, even as far as Scotland, and laid on beds or layings in creeks along the shore, where they grow, in two or three years, to a considerable size, and have their flavour improved. There are said to be about 200 vessels, from 12 to 40 or 50 tons burden, immediately employed in dredging for oysters, having from 400 to 500 men and boys attached to them. The quantity of oysters bred and taken in Essex, and consumed mostly in London, is supposed to amount to 14,000 or 15,000 bushels a year. (*Supp. to Ency. Brit.*, art. "Fisheries.") Oysters formed a great luxury among the Romans, and, as in France, were served at the commencement of a repast. The largest and best of Italy were caught on the shores of the Lucrine; but the Romans used to send vessels even to the coast of Britain in quest of this luxury, the British oysters being then as now in the highest estimation.

OZÆ'NA. (Gr. οζω, *I smell.*) An ulcer in the nose which discharges a fœtid purulent matter, and is sometimes symptomatic of caries of the bones.

P.

P. A consonant of the labial series. As was to be expected from the approximation of this letter in sound to *b*, it is susceptible of interchange with the latter in nearly all the languages of which we have any knowledge, but more especially in the German. Both in this country and on the Continent there are whole districts in which not only is the ear of the natives insensible to the difference between the sound of these letters, but, with a tendency to error of which it would be vain to investigate the cause, they are almost invariably confounded in pronunciation. Of this peculiarity several counties of Wales among ourselves, and the whole of Lower Saxony in Germany, present noted examples. For the most usual abbreviations of this letter, see ABBREVIATION.

P. In Music, an abbreviation of the Italian word *piano*, soft, denoting that the force of the voice or instrument is to be diminished. P.P. means *piu piano*, or more soft; and P.P.P. *pianissimo*, as soft as possible.

PACE. (Fr. pas.) A denomination of linear measure, of uncertain extent; assumed by some to be 5 feet, by others 4·4. It is the quantity supposed to be measured by the foot from the place where it is taken up to that where it is set down. The ancient Roman pace, considered as the thousandth part of a mile, was five Roman feet, and each foot contained between 11·60 and 11·64 modern English inches; hence the pace was about 58·1 English inches, and the Roman mile, the *mille passus*, equal to 1614 yards. *See* MILE.

PA'CHA. (Pronounced *pasha;* contracted from the Persian padi shah, *foot of the shah.*) A title of honour, given in the origin of the Turkish empire to the ministers and chief assistants of the sultan, whether military or learned. (See *Von Hammer's History of the Turkish Empire*, vol. i. p. 137.) In process of time attributed particularly to the governors of provinces, styled *pachaliks.* The well-known distinction of rank between the two classes of pachas consists in the number of horse-tails which are carried before them as standards, the higher having three and the lower two. There were until recently 25 pachaliks, subdivided into sangiacates, besides various independent jurisdictions scattered over the empire.

PA'CHACA'MAC. The name given by the idolaters of Peru to the being whom they worshipped as the creator of the universe; this divinity was held in the highest veneration. In the fruitful valley of Pachacama (whence the name) the incas dedicated to his honour a temple of such splendour and wealth, that notwithstanding the rapacity of the Spanish soldiers, by whom it was plundered previously to the arrival of Pizarro, that general is said to have drawn from it treasures to the amount of 900,000 ducats. The ruins of this temple which still remain furnish a high notion of its former magnificence.

PA'CHYDE'RMATA. (Gr. παχυς, *thick*, and δερμα, *skin.*) An order of quadrupeds, including the elephant, horse, pig, &c., distinguished by the thickness of their hides.

PACHYGLOSSATES, *Pachyglossi.* (Gr. παχυς, and γλωσσα, *a tongue.*) The name of a family of parrots (*Psittacini*), comprehending those which have a thick protractile tongue.

PACHYO'TES, *Pachyoti.* (Gr. παχυς, and ους, *an ear.*) The name of a family of bats (*Cheiroptera*), including those which have thick external ears.

PACI'FIC. The name given by Magalhaens, the first European who traversed it, to the ocean which extends between America on the east and Asia and Australia on the west, in consequence of his enjoying fair weather on entering it, after having previously experienced a track of bad weather and tempestuous gales in the straits which bear his name. The Pacific is the greatest expanse of water on the globe.

PACIFICA'TION, EDICTS OF. The term usually applied to the edicts issued by the French monarchs in favour of their Protestant subjects, in the view of allaying the commotions occasioned by their previous persecutions. The first edict of this nature was promulgated by Charles IX. in 1562; but the most celebrated was the edict of Nantes (which see), issued by Henry IV. in 1598, and revoked by Louis XIV. in 1685.

PA'CKET, in Navigation, meant originally a vessel appointed by government to carry the mails between the mother country and foreign countries or her own dependencies. It is now used as nearly synonymous with an ordinary vessel, chiefly of small burden, that freights goods or passengers.

PA'CKFONG. The Chinese name of the alloy of nickel and copper commonly called *German silver.* It is an alloy of 7 parts of zinc, 2·5 copper, and 6·5 nickel.

PACK-HORSE. A horse employed to carry goods on its back in bundles, called packages or packs. In countries not yet intersected by regular roads this is the only mode of transporting goods from one part to another. In Britain horses were formerly employed for this purpose, but for these carts and waggons are now substituted. In Spain mules and asses are still so employed, and in Asia and Africa camels and dromedaries.

PA'COS. The Peruvian name of an earthy-looking ore, which consists of brown oxide of iron, with imperceptible particles of native silver disseminated through it. (See *Ure's Dictionary of Arts, &c.*)

PA'DDING, in Calico-printing, is the impregnation of the cloth with a mordant.

PA'DDLE. A kind of oar used by savage nations in navigating their canoes. The paddle is broader at the end than the common oar; and being employed at the stern of the canoe, not only impels her forwards, but regulates her course exactly like a rudder. *See* SCULLING.

PADDLES. *See* STEAM NAVIGATION.

PA'DDOCK. This term was formerly applied to a strip of ground in a park, pailed round, for hounds to run matches in; but at present it is chiefly used to denote a small enclosure under pasture, immediately adjoining the stables of a domain, for turning in a sick horse, a mare and foal, or any similar purpose.

PADI'SHA. (From pad, *protector* or *throne*, and

shah, *prince.*) A title of the Turkish sultan and Persian shah. Formerly the Turkish emperor conferred this title upon the kings of France alone among the European sovereigns, but we believe that the honour is now likewise shared by the emperors of Austria and Russia. *See* PACHA.

PA'DUAN COINS. In the Fine Arts, coins forged by the celebrated Paduans, Cavino and Bassiano; who were also the artists employed on the pope's medals, from Julius III. to Gregory XIII. (1571). These coins hold the first rank in imitations of ancient medals for their masterly execution. M. Beauvais says of them, "that they are seldom thinner than the ancient coins themselves; that they seldom appear as worn or damaged, whilst others very frequently do, especially in the reverse, which sometimes, as in many Othos, appears half consumed by time; and while (he observes) counterfeit medals are very commonly of as irregular a form as the real, those of the Paduan masters are generally circular." Still more modern forgers, who were without the talents which these Paduans possessed to engrave dies, have been content to mould them from their productions; but these are cast coins, which it requires no very extraordinary knowledge to detect. The marks of the file upon their edges are mostly a sure sign of the imposition; those, however, who collect these objects of art should be constantly on their guard.

PÆ'AN. (Gr. Παιάν.) Among the Greeks, properly a hymn in honour of Apollo, who was also called Pæan. Also a war song before or after battle: in the first case in honour of Mars, in the second as a thanksgiving to Apollo.

PÆAN. In Ancient Poetry, a foot consisting of four syllables, of which there are four kinds; the Pæan primus, secundus, &c. *See* FOOT.

PÆ'DOBA'PTISTS. (Gr. παις, *a child*, and βαπτιζω, *I baptize.*) Those who hold that baptism should be administered during infancy. The great majority of Christian churches which allow the baptism of infants are thus denominated from that circumstance, and are thereby distinguished from the Antipædobaptists, *i. e.* those who deny the validity of infant baptism. *See* BAPTISTS.

PA'GAN (Lat. paganus; from pagus, *a village*), among the Romans, was, as the term imports, applied to all who lived in villages, in contradistinction to the inhabitants of cities. In its present signification it is the opposite of *Christian*, being synonymous with heathen, gentile, and idolater; and was originally so applied because the inhabitants of villages continued to adhere to their idolatrous practices after Christianity had been introduced into towns and cities. The precise period when the term pagan was first used in its present acceptation has not been ascertained. *See* HEATHEN.

PAGANA'LIA. (Lat.) Festivals held in each Roman village in honour of the local tutelary divinities. They were instituted by Servius Tullius, who commanded every inhabitant of each *pagus*, or village, to assemble annually on a certain day, and offer public sacrifices. In instituting these festivals Servius had both a political and religious object in view; for, as every inhabitant was compelled to bring a small coin, varying with the age and sex of the bearer, he was annually acquainted with the strength of each district, and consequently with that of the kingdom.

PA'GANISM. A general appellation for the religious worship of the whole human race, except of that portion which has embraced Christianity, Judaeism, or Mohammedanism. Under the head POLYTHEISM, we have given a brief outline of the different kinds of pagan worship, and we shall in this place confine our remarks to the origin of the system.

That in the most ancient times one God, sole, eternal, indivisible, the creator of the universe, was acknowledged and worshipped, has been proved by the most profound investigators of antiquity. The existence of this belief may not only be traced in the tradition of all people, but is expressly affirmed by some of the greatest philosophers of the heathen world. Nothing, indeed, could exceed the contempt with which some of them regarded the gods of the vulgar, though fear of danger or some other cause often taught them to conceal the sentiment.

The causes of idolatry were manifold, and were mostly of oriental growth. A great king regarded it as below his dignity to enter into the minute details of administration: he placed vicars or ministers over provinces and cities, over the great departments of national polity. If the onerous charge was inapplicable to an earthly, it was still more so to the celestial Sovereign: hence the subordinate deities which we perceive in the religious systems of all nations, — the presiding genii of the Chaldæans, the numerous gods of Greece and Rome. The worship due to the Supreme alone was soon transferred to those imaginary entities, which, from functionaries, were transferred into so many independent chiefs, until the simple primeval notion of the divine unity was lost. The other causes of idolatry are foreign to our purpose: the one already assigned, which is indisputably the most ancient and the most obvious, is of itself sufficient to account for the fact.

In its origin paganism, as a system, was simpel. A few great divinities were placed in heaven to guide the affairs of the visible and invisible worlds. By degrees each great planet, each law of nature, each region and city, nay each river, fountain, wood, tree, mineral, had its tutelary divinity. The laws of nature were often inexplicable; what more obvious than to infer that each was subject to a superior power? As the ideas of men became more precise and refined, gods were placed over human faculties and passions: thus the understanding and the will, love and revenge, were the offspring of certain deities. Mere abstractions were similarly personified; until the empire of reason, of sentiment, and of morals, was as much pervaded as earth, air, and ocean with these visionary beings. But might not men themselves attain to that mysterious dignity? might they not become at least a sort of demigods,—a distinction earned by some uncommon merit? In all countries we find instances of deification. Nor need this surprise. The human mind is naturally prone to exaggeration, — the human heart to be led astray by the intensity of its own feelings. Thus he who, during life, proved himself a benefactor to his countrymen, who taught them useful arts, or freed them from some impending evil, would be regarded with affectionate admiration by his contemporaries; and time, which so constantly increases every object, would convert a great exploit, a shining virtue, into a divine effort. But it not unfrequently happened that men were often deified for brute strength, unaccompanied by those elevated mental qualities which form the noblest distinction of the hero. It may, however, be observed, that in such cases men were always reverenced for the quality most wanted in a state. If a district were infested by wild beasts, or by predatory savages, a Hercules arose to free it. If a country required laws, a Minos established them. If the culture of the grape was unknown, a Bacchus appeared to teach it. Such benefactors, it was believed, deserved, as they certainly obtained, the peculiar favour of heaven, — rewards which far transcended those bestowed on other men. In most cases, however, each was held to be a divinity, or at least the offspring of one. As the generation of the gods was a received tenet, and their union with mortals of constant occurrence, imagination had little difficulty in the filiation of a benefactor. Most nations were eager to proclaim a god as their founder; and when one laid claim to the honour, the example was speedily followed by others with equal appearance of justice. Hence the prodigious number of divinities; heaven and hell, the earth and the planets, air and ocean, the whole frame of nature, every part of the universe, visible and invisible, even the realms of imagination, being pervaded by them; and hence idolatry became a complicated system, endless in its forms of worship as in its objects.

It has indeed been contended that even in the most unenlightened times, men — except, perhaps, the grossest in comprehension — were never so absurd as to receive this almost infinite plurality of deities; that each derived its name from its being a distinct manifestation of the divine energy; that the Neptune of the sea, the Apollo of the sun, the Minerva of the understanding, the Jove of the thunder, were mere denominations, founded on the distinct modes in which the Supreme manifests himself to the world: in short, that those denominations were but so many imaginative terms for the emanations of the all-pervading Deity; and that under each distinct emanation this deity might be worshipped without the charge of idolatry. But this hypothesis is too refined to be just, and is contrary to experience. The known progress of the human mind is from sensual to ideal, not from the ideal to the sensual; philosophy is the end, not the beginning of knowledge. If that great patriarchal truth, the unity of the Godhead, was obscured by successive ages of ignorance, it could be regained only by an opposite and equally laborious process of the intellect; and even when thus recovered, it could not be communicated without danger to the multitude. (*Cab. Cyc.; Arts, &c. of the Greeks and Romans*, vol. ii.) *See* MONOTHEISM.

PAGE. (Modern Latin pagius, of uncertain derivation; according to some, from pagus, *village.*) In high life, a youth attached to the service of a royal or noble personage. In the ancient Persian court (which has been not ill termed the archetype of all courts), we find the usage of employing a number of youths of the noblest families of the empire in personal attendance on the sovereign. Among the Greeks and Romans (to whom monarchical institutions, strictly so called, were unknown), no analogous custom appears to have prevailed. Among the northern nations, on the other hand, personal service of this sort was common. The name pages, however, appears confined to slaves and attendants of an inferior description, in modern Europe, until the reigns of Charles VI. and VII. of France. (*Fauchet's Origine des Chevaliers.*) As chivalric institutions prevailed, the office, by whatever

name called, became of importance; courts and castles were the schools in which the young noble passed through the degree of page, in order to reach the farther steps of esquire and knight, when he became "hors de page." In the 16th century the chivalrous character had become much adulterated; but the custom of bringing up sons as pages at courts continued until the disorder and licence of the age rendered the service so dangerous that it was no longer sought by the better classes as a mode of education for their children. Pages then became, as they are now, mere relics of feudal custom: from some courts (the Prussian, for instance) they have entirely disappeared; and the young noblemen of the cadet school perform the office of pages on solemn occasions. (See Sainte-Palaye, *Memoires sur la Chevalrie; Mem. de l'Ac. des Inscr.* vol. xx.)

PAGE. In Printing, one side of the leaf of a book. A folio volume contains 4 pages in every sheet; a quarto 8, an octavo 16, a duodecimo 24, and an octodecimo (18mo.) 36 pages.

PA'GEANT, in its general sense, a public representation or exhibition of a showy and splendid character. It was a very early custom in the middle ages, both in England and on the Continent, to celebrate festive occasions of a public nature, as royal visits, marriages, &c., by some ornamental show in the public streets of cities. During the period of chivalry these shows began to be exhibited with the addition of masked figures, representing allegorical personages, with appropriate scenery; and as, in process of time, speeches in verse or prose were put into the mouths of these figures, and sometimes a kind of dramatic entertainment performed between them, the pageant consequently holds a place in our early literature. The earliest speaking pageant of which we have any account was presented on the triumphal entry of Henry VI. into London, in 1432; and the poetical part of it is conjectured to have been supplied by Lydgate. The reign of Henry VIII. was fertile in pageants of an extraordinary magnificence and splendour; but in that of queen Elizabeth they assumed a different form, and were both devised and enacted with much more elegance: partly from the tincture of romantic gallantry which distinguished the court of the maiden queen, and was perceptible in all the homage rendered to her by her subjects, and partly from the sudden development of the poetical genius of the nation. The pageants gradually became more dramatic, and thus approximated more nearly to the more elegant character of the masque (*see* MASQUE), which, under her successor, became the fashionable court entertainment. Pageants, however, were still presented by the city of London, which retained a poet laureat of its own for the purpose of inditing the spoken part of them, down to the year 1700, or thereabouts; and the lord mayor's procession still retains some characteristics of these ancient entertainments. The derivation of this word is wholly unknown, and has afforded much scope to the fancy of etymologists.

PA'GINA. (Lat.) In Botany, the surface of a leaf.

PAGO'DA. (Pers. poutghad, *a house of an idol.*) In Architecture, the East Indian name for a temple containing an idol. Sometimes it signifies the idol itself. The pagoda is generally of three subdivisions. First, an apartment whose ceiling is a dome resting on columns of stone or marble: this part is open to all persons. Second, an apartment forbidden to all but brahmins. Third and last, the cell which contains the statue of the deity, enclosed with a massy gate.

PAGODA, is also the name of a gold coin, value from 8*s.* to 9*s.*, current in several parts of India. It is also the name of a silver coin of the same value, on which are stamped images of the Hindoo gods.

PA'GODITE. A species of steatite or serpentine, which the Chinese carve into figures.

PAGU'RIANS, *Paguridæ.* (Lat. pagurus, *hermit-crabs.*) The name of a tribe of Macrurous Decapod Crustaceans, of which the genus *Pagurus* is the type. Most of the species of this family inhabit, parasitically, the deserted shells of univalves.

PAI'NIM. A poetical expression used by English writers for *pagan.*

PAINS AND PENALTIES, BILL OF. A species of process employed to inflict punishment on state offenders out of the ordinary course of justice. Every bill brought into parliament for the purpose of inflicting such punishment is a bill of pains and penalties, of which bills of attainder (*see* ATTAINDER) are, properly speaking, a species; but the term is more commonly confined to bills introduced to inflict specified penalties for particular acts. The latest instance of this extraordinary proceeding was the bill of pains and penalties against Queen Caroline (1820), introduced into the House of Lords, and passed by them, but which was not carried into the Commons.

PAI'NTER. In Naval language, a rope used to fasten a boat either alongside of the ship to which it belongs, or to some wharf, quay, &c., as occasion requires.

PAI'NTERS' COLIC. The peculiar disease, which usually terminates in palsy and mental imbecility, to which painters and others subject to lead poisons are subject. It is also called colic of Poitou and Devonshire colic; the miners employed in lead-works being also liable to its attacks. *See* COLIC.

PAI'NTING (Fr. peinture, Lat. pictura), strictly defined, is an art which, by means of lines and colours, represents on a plane surface all objects presented to the eye or to the imagination. The etymology of the word (γραφειν) used to express painting among the Greeks, being the same as that employed for writing, seems to identify the tools with which it was performed among that people: viz. a style or pen of wood, used on a levigated plane of wood, metal, or some other prepared ground; the mode, letters or lines. Until its operations become founded on the faithful representations of visible objects of nature, undisfigured by mannerism and modification from the fashion and habits of a country, such, for instance, as we meet with in the Indian, Egyptian, and Chinese representations of the human form, it is scarcely entitled to the appellation of art; hence we shall, in this article, dismiss, with very few remarks, its appearance in those countries where traces of it in that condition are to be found, reserving the principal part of this article for that development, simplicity of end, and uniformity of pursuit, which enabled the Greeks, the great arbiters of form, to carry it to a degree of excellence which no subsequent age or nation has been able to reach, or even rival.

It seems probable that drawing and recorded language were coeval in invention. In Greek we have mentioned that the same word (γραφειν) expressed the act of performing one as well as the other. Goguet, in his *Origine des Loix*, says that the first essay of the art of writing, using the expression in its most general sense, was by means of the representation of corporeal objects. Its invention would thus be carried back to a period almost as remote as that of the existence itself of the human race. The earliest people, he says, naturally used this method for exhibiting their thoughts, and commenced by representing to the eye the objects they wished to impress on the mind. The origin, however, of painting, properly so called, involved as it is in the greatest obscurity, presents one of the most difficult questions in the history of the arts; and opinions are very much divided as to the country that gave birth to it. Some authors have assigned its invention to a period antecedent to the siege of Troy. (*Plin.* l. vii.) Others, to one long after. (*Plin.* l. xxxv.) Pliny says, that the Egyptians boasted of being acquainted with the art six thousand years before the Grecians; but his words are, "Affirmant, vana prædicatione, ut palum est." Profane no less than sacred history rejects such a chimæra. But, though such a period of antiquity be fabulous, it is quite certain that painting was much used by them at a very early period. It is argued by Goguet that, as much as it was in his power, Cambyses destroyed the monuments of art he found in Egypt. Hence may be considered as posterior to his invasion such of the monuments as display specimens of the art. The epoch whereof we are speaking is 525 B. C. This, however, is an argument far from satisfactory, where all is conjecture. The specimens of Egyptian paintings now extant exhibit a collection of representations of human and other figures which indicate extremely slender advances in the art. They are all rudely and falsely drawn: no notion of grouping, as we understand it, nor sentiment, appears in any of their productions. As the Phœnicians were an early cultivated people, and have the credit of the invention of letters, they may, perhaps, have a claim to the invention equal to that of any other nation. In the time of Solomon, 992 B. C., they were so well skilled in the arts that that king employed them in building the temple. The Scriptures record the magnificence and splendour of their buildings, abounding with decorated apartments and sculptured ornaments; and we know, from the coins of the Phœnicians that have reached us, that in the design and execution of their coinage they were not far behind the Greeks.

"Thou, also, son of man, take thee a tile, and lay it before thee, and pourtray upon it the city, even Jerusalem," are the words with which the fourth chapter of Ezekiel commences; the words in the Septuagint being διαγράψεις ἐπ' αὐτὴν πόλιν τὴν Ἱερουσαλήμ. This is about 590 B. C., and would tend to show that the art was practised by the Jews so early as that period. The commandment, "Thou shalt not make to thyself any graven image," which some sects, even in the present day, construe into a prohibition against all art, was merely a prohibition of the worship of idols; for we find Moses himself, by the command of God, employing sculpture for the sanctuary. The employment of art of this nature is found, also, in many other passages of Scripture, which will doubtless occur to the reader.

The Persians, the Arabians, and the Parthians, from the peculiar opinions they entertained, could have no claims either to the origin or improvement of the art of painting. With them the representation of the human

figure in a state of nudity was considered almost as indecorous as the appearance before them of a naked man himself. Their figures are clothed almost invariably with drapery, falling in clumsy folds profusely plaited. Worshippers of fire, they used no representations of the Deity; and it is curious that, in their successful invasion of Egypt, they imbibed no taste for the arts and religion of that polytheistic country — not that they had, perhaps, in the former, much to acquire.

The art of painting in China, if we may judge of it from the time it first became known in this country, has remained the same time immemorial. It has never exceeded the bounds of imitation, and even in that respect it is devoid of taste and truth. The human figure with the Chinese is a distorted misrepresentation, and their perspective is attained by piling one object on the top of another till the picture is all earth and no sky. Invention and imagination were never known among them; and though in many respects ingenious in manipulation, their dexterity is exhausted in painting the fins of a fish, or the petals of a plant. In such a country it would be vain to look for the origin or progress of the art.

Etruscan art is known to almost every person by the vases that bear that name. In the article ARCHITECTURE we have touched upon the perfection, at a remote period of time, of the arts of Etruria; a country which, in its ancient state, was the most powerful and civilized in Italy. Diodorus speaks of the rich and powerful cities in their territories, and of the uncontrolled sway which their fleets exercised on the seas encircling the peninsula. Though the history of this nation is involved in obscurity, though the Romans strove to remove all the memorials of their ancient fame, sufficient information has reached us to demonstrate the height of perfection to which they carried the fine arts. About twelve miles from the town of Civita Vecchia stood the ancient Etruscan city of Tarquinia, near which are found a considerable number of sepulchral grottos, whereof some are decorated with paintings and figures much in the style of those on the Etruscan vases. These antiquities have been published, with a detailed description and plates, by the late Mr. Byres. Some of the pictures represent combats, and in others the subjects are dances of females, all executed with considerable spirit. The pottery, however, which we have above noticed, appears to afford the greatest number of their specimens of the arts of design: the forms displayed in the contours of the vases, no less than the paintings with which they are decorated, evince a wonderful attainment of elegance in design, purity of form, and ingenuity in its delineation. The power over line, and the facility of execution they reached, may be easily conceived from the absorbent nature of the material upon which they wrought. No retouching was possible; but the whole must have been completely arranged in the mind before it could be struck off by the artist. Pliny states that, in his day, the town of Ardea, an ancient city of Etruria, contained some paintings which he ascribes to a period anterior to the foundation of Rome, and mentions with surprise their then perfect state of preservation. At Lacuvium, also, he describes some pictures of Atalanta and Helen, which were simply painted on the wall, and exhibited great merit in execution. These Caligula, after a fruitless attempt, failed in removing. Cere, another Etruscan city, boasted some paintings of an early date. All these specimens are doubtless of a remote epoch; but attempts to fix it with precision would not be likely to bring us to the exact or even proximate period of their execution. The history of painting, however, can only be told under the head of Grecian art, to which we shall now proceed, premising that in our account we shall use most freely the *Lectures on Painting* of the late Henry Fuseli, professor of painting of the Royal Academy, who, whatever may be thought of his pictures, was an enthusiastic lover of his art, a scholar, and a critic of the highest order.

The vocabulary of the technical expressions, *nature*, *beauty*, *grace*, *taste*, *copy*, *imitation*, *genius*, and *talent*, is explained as follows: — By *nature* is meant the general and permanent principles of visible objects, neither disfigured by accident nor distempered by disease, neither modified by fashion nor local habits. *Beauty* is that harmonious whole of the human frame, that unison of parts to one end, which enchants us. It is the result of the standard set by the great masters of the art, the ancients, and confirmed by modern imitation. *Grace* is an artless balance of motion and repose, springing from character, founded on propriety, and neither falling short of the demands nor overleaping the modesty of nature. Applied to execution, it is that dexterous power which hides the means by which it is attained. By *taste* is meant not crudely the knowledge of what is right in art, but an estimation of the degrees of excellence by comparison, proceeding from justness to refinement. *Copy*, though generally confounded with *imitation*, is essentially different in operation and meaning. Precision of eye and obedience of hand are the requisites of the former, without pretence to choice or selection; whereas choice, directed by judgment or taste, is the essence of imitation. "Of *genius* I shall speak with reserve," says the professor; "for no word has been more indiscriminately confounded:" by genius is meant the power which enlarges the circle of human knowledge, which discovers new materials of nature, or combines the known with novelty; whilst *talent* arranges, cultivates, and polishes the discoveries of genius.

Religion was the motive of Greek art; it was therefore natural that they should endeavour to invest their own authors, for they considered themselves of divine origin, with the most perfect form; and as man possessed that exclusively, they completely and intellectually studied his elements and constitution. The climate that was favourable to the development of that form, the establishment of exercises by their civil and political institutions, created models in nature which raised Greek art to the highest excellence.

Skiagrams, or simple shaded outlines, similar to those known under the name of *silhouettes*, were the first essays of the art. They had no addition of character or feature but what the profile of the object thus delineated could afford. "Greek art had her infancy; but the Graces rocked the cradle, and Love taught her to speak. If ever legend deserved our belief, the amorous tale of the Corinthian maid, who traced the shade of her departing lover by the secret lamp, appeals to our sympathy to grant it."

The next step of the art was the *monogram*, which is the outline of figures without light or shade, with the addition, however, of parts within the outline. From this to the *monochrom*, or painting of a single colour on a tablet primed with white, then covered with what was called punic wax, first amalgamated with a resinous pigment, generally of a red, sometimes of a dark brown or black colour, was the next advance. Through this inky ground the outlines were traced with a firm though pliant *style*, called a *cestrum*: the line could be altered with the finger or a sponge, and easily replaced by a fresh one. When the whole was settled it was suffered to dry, and covered with a brown encaustic varnish; the lights were worked over again, and rendered more brilliant with a more delicate point, according to the gradual advance from mere outlines to some indication, and at last to masses of light and shade: thence to the superinduction of different colours, or the invention of the *polychrom*, which, by the addition of the pencil to the style, raised the stained drawing to a legitimate picture, and at length produced that vaunted harmony, the magic scale of Grecian colour. If these conjectures be founded in fact, the supposed momentaneous productions on the Etruscan vases, which we have above noticed, would be no longer matter of astonishment; and indeed it appears much more likely that such should have been the case, than that the figures so drawn should have been "the magic produce of a winged pencil," rather than "the result of gradual improvement exquisitely finished *monochroms*."

The period at which the pencil supplanted the cestrum cannot be ascertained. Apollodorus, in the 93d Olympiad, and Zeuxis, in the 94th, are said to have used it with freedom and power; Parrhasius painted the battle of the Lapithæ and Centaurs on the shield of the Minerva of Phidias, to enable Mys to chase it; but this was most probably a monochrom, designed with the cestrum for greater accuracy. It was nearly a century after this that Apelles and Protogenes had a competition in drawing lines with the pencil, in which delicacy and evanescent subtlety being the characteristic, some notion of their mechanical skill may be formed. Of the *encaustic* method used by the ancients no account can be given on which reliance may be placed. "The most probable account," says Fuseli, "is, that it bore some resemblance to our oil painting; and that the name was adopted to denote the use of the materials inflammable or prepared by fire, the supposed durability of which, whether applied hot or cold, authorized the terms *ἐνεκαυσε* and *inussit*."

Polygnotus is the first great name that appears on record at a period when some satisfactory history of the art might be commenced. He flourished about 400 years B.C. So great was his success in the Pœcile at Athens, and the Lesche or public hall at Delphi, that, in a general council of the Amphictyons, it was solemnly decreed that his expenses, whenever he travelled in Greece, should be borne at the public charge. From the description of his pictures by Pausanias, it would seem that composition in painting, as we now understand that term, was not at all understood, inasmuch as that author begins his description at one end of the picture and finishes at the opposite extremity, which indicates pretty plainly that there could be no central group or figure to which the rest were subordinate. Aristotle says that Polygnotus improved his model; and it would be unjust to pronounce, considering the variety of powers by which the parts of his pictures were distinguished, that the primitive arrangement we have just mentioned arose from want of comprehension in the artist.

After Aglaophon, Phidias Panænus, Colotes, and Eve-

nor, the father of Parrhasius, came Apollodorus, the Athenian. "This painter applied the essential principles of Polygnotus to the delineation of the species, by investigating the leading forms that discriminate the various classes of human qualities and passions. The acuteness of his taste led him to discover that as all men were connected by one general form, so they were separated each by some predominant power which fixed character and bound them to a class." Pliny and Plutarch considered Apollodorus as the first colourist of his age. It is probable from their descriptions that he was the inventor of local colour and tone, which received from the former the term splendour. Zeuxis succeeded to Apollodorus, and, by uniting in one figure the most perfect parts of many models, produced an ideal form, which, in his opinion, constituted the supreme degree of human beauty. Lucian describes a picture he exhibited at the Olympic games as remarkable for its invention. It was the representation of a female Centaur suckling her young, and the account is to be found in the memoir inscribed with the name of Zeuxis. This artist used but few colours; but he seems to have understood the extension of light to masses, from the circumstance of his painting monochroms on a black ground, adding the lights in white. "Pinxit et monochromata ex albo," says Pliny.

Parrhasius, a native of Ephesus, but a citizen of Athens, was the son and disciple of Evenor, and cotemporary of Zeuxis. By his subtle examination of outline, he "established that standard of divine and heroic form which raised him to the authority of a legislator from whose decisions there was no appeal. That he was a thorough master of allegory is evident from his embodying by signs, universally understood, the Athenian people (ΔΗΜΟΣ), in which he expressed at once its contradictory qualities. "Perhaps," observes Fuseli, "he traced the jarring branches to their source, the aboriginal moral principle of the Athenian character, which he made intuitive. This supposition alone can shed a dawn of possibility on what else appears impossible." In his competition with Timanthes the Cythnian, or, as some say, of Sicyon, he had the mortification to have been declared by a majority of votes inferior to him. The subject of the competition in which he was thus defeated was the contest of Ajax and Ulysses for the arms of Achilles.

No picture of antiquity has acquired so much celebrity as the sacrifice of Iphigenia in Aulis by Timanthes. Quintilian informs us that it was painted in contest with Colotes of Teos, an artist from the school of Phidias, and crowned with victory at its rival exhibition. This picture, which has been the subject of the unlimited praise of critics of antiquity, has, in modern times, been the subject of criticism, from the circumstance of Timanthes hiding the face of the father (Agamemnon) of the victim to be immolated in his mantle, unable by his art to express the intensity and agony of his grief. Upon this Sir Joshua Reynolds observes, in his Eighth Discourse, "If difficulties overcome make a great part of the merit of art, difficulties evaded can deserve but little commendation." The French critic, Falconet, has not been less unsparing than the president in his condemnation of the artifice. The answer of Fuseli to these critics appears to us satisfactory. He says, "The subject of Timanthes was the immolation of Iphigenia. Iphigenia was the principal figure; and her form, her resignation, or her anguish, was the painter's principal task: the figure of Agamemnon, however important, is merely accessory, and no more necessary to make the subject a completely tragic one than that of Clytemnestra, the mother; no more than that of Priam, to impress us with sympathy at the death of Polyxena." Again, "They ascribe to impotence what was the forbearance of judgment. Timanthes felt like a father; he did not hide the face of Agamemnon because it was beyond the power of his art,—not because it was beyond the possibility, but because it was beyond the dignity of expression; because the inspiring feature of paternal affection at that moment, and the action which of necessity must have accompanied it, would either have destroyed the grandeur of the character and the solemnity of the scene, or subject the painter with the majority of his judges to the imputation of insensibility." The same expedient to express grief was adopted by Michael Angelo in the figure of Abijam, and by Raphael in the Expulsion from Paradise, borrowed from Masaccio. These were the artists who formed the second school of art, and established its end and limits. On it was founded the third period of style, in which refinement induced a grace and beauty to forms not to be surpassed. The masters of this period were Apelles, Protogenes, Aristides, Euphranor, Pausias, and the pupils of Pamphilus and his master Eupompus. This last-named artist was of Sicyon; and his authority was so great that out of the Asiatic and Grecian schools of painting he formed a third, by dividing the last into the Attic and the Sicyonian. When consulted by Lysippus (*Pliny*, l. xxxv.) on a standard of imitation in art, he pointed to the crowd passing by; observing that nature, not an artist, should be the object of imitation. Pamphilus, a Macedonian, the master of Apelles, and the most scientific artist of his day, adopted the doctrines of Eupompus. To the art of painting he joined the study of mathematics, and held the opinion that without the aid of geometry no painter could ever arrive at perfection. In Apelles of Cos, or, according to Lucian, of Ephesus, we are told by Pliny unrivalled excellence was found. Grace was his powerful and peculiar faculty, in which, and in knowing where to stop, he surpassed all that preceded him, and left not his equal in the world. The story of the lines which were drawn by himself and Protogenes in competition with each other is not a legendary tale, but a well-attested fact: into the nature of them, however, it would be now useless and unavailing to inquire. Aristides of Thebes, and cotemporary of Apelles, was the first who, by the rules of art, attained a perfect knowledge of expressing the passions and affections of the mind. The history we have of the picture which Alexander, at the sacking of Thebes, sent to Pella, proves his power of infusing the passions into his works. In it were expressed the anguish of maternal affection and the pangs of death. Euphranor, the Isthmian and pupil of Aristides, is said to have carried still farther the refinements of that expression so powerful in the hands of his master. Skilled in sculpture as well as painting, his conceptions were noble and elevated, his style masculine and bold; and he was the first who distinguished himself by imparting majesty to his heroes.

Asclepiodorus, the Athenian sculptor as well as painter, was, as the latter, celebrated for the beauties of a correct style and the truth of his proportions. Apelles allowed himself to be, in these respects, as much inferior to this artist, as he was to Amphion in the good ordering and disposition of his figures. About this period appeared Nichomachus, Nicophanes, Pyreicus, and others. Nicias, an Athenian, 322 B. C., was in great repute for the great variety and noble choice of his subjects, for the mode of distributing his lights and shadows, and for consummate skill in the representation of quadrupeds. In Rome, about 301 B. C., Fabius, a noble Roman, painted the Temple of Health, and gloried so much in the art that he assumed the surname of Pictor. Without a further enumeration of masters we may add, that for a long period after the reigns of Vespasian and his son Titus, painting as well as sculpture continued to flourish in Italy. Even under their successors, Domitian, Nerva, and Trajan, they met with as much encouragement as in the most palmy state of the arts in Greece. Under Adrian, Antonine, Alexander Severus, Constantine, and Valentinian, the art of painting continued to be an object of interest; but at length, in the reign of Phocas, with the fall of the empire, with the rest of the noble arts and sciences, it was involved in the common heap of ruins.

Painting in Italy owes the dawn of its restoration to the feeble rays that emanated from the pencil of Giovanni Cimabue, who was nobly descended, and born at Florence in the middle of the thirteenth century. He was the disciple of some indifferent painters, who had been brought from Greece by the government of Florence: these he soon surpassed both in drawing and colouring. Without the art of managing his lights and shadows, and but slenderly acquainted with the rules of perspective, he nevertheless laid so firm a foundation for the future improvement of the art, as to entitle him to the name of the father of the first age of modern painting. His death took place in the year 1300 at Florence, where, and at Pisa, some of his productions are still to be seen. Giotto, his pupil, also a Florentine, was a more able painter than his master. He divested himself of the shackels in which the system of the Greek art of that age had bound his master, adding somewhat of grace to his figures and nature to his colouring. Of a picture which he painted in the church D'Ogni Santi at Florence, representing the death of the Virgin with the Apostles about her, Vasari related that M. Angelo da Buonaroti used to say that the truth could not be nearer approached than in it—"Non potere essere più simile al vero di quello, ch' èra." He was the friend of Dante and Petrarch, and painted the portrait of the former. On his decease, in 1336, the city of Florence erected his statue in marble over his tomb.

In the year 1410, thirty years before the invention of printing by Gutemburg, John Van Eyck, born in the Low Countries in 1370, is understood to have invented the art of painting in oil, which he taught to Antonello of Messina, who visited Flanders to become acquainted with the secret: he it was who first practised and taught it in Italy. The principal masters who flourished in this first period of the resuscitation of the arts were Andrea Orgagna, so celebrated for his Loggia in the great square at Florence, Pietro Cavallino, Stefano, Bonamico, Buffalmacco, Pietro Laurati, Lippo, Spinello, Casentino, Pisano, &c. The art did advance, though but slowly, gathering little strength till the appearance of Masaccio. "Sculpture had already produced respectable specimens of its reviving powers in the bassi-relievi of Lorenzo

Ghiberti, some works of Donato, and the Christ of Philippo Brunelleschi, when the first symptoms of imitation appeared in the frescos of Tommaso da San Giovanni, commonly called Masaccio, from the total neglect of his appearance and person. Masaccio first conceived that parts are to constitute a whole; that composition ought to have a centre, expression truth, and execution unity: his line deserves attention, though his subjects led him not to investigation of form; and the shortness of his life forbade his extending those elements which Raphael, nearly a century afterwards, carried to perfection." Masaccio, who was born in Tuscany in 1417, is considered the father of the second or middle age of painting. His death, caused, it is supposed, by poison, occurred in 1443. Andrea Montegna, born at Padua in 1431, was a disciple of Jacopo Squarcione. Though correct in his drawing, well versed in perspective, and apparently acquainted with the antique, albeit the best antique statues had not then come to light, his neglect of nature induced a crudeness of taste and grotesqueness of fancy. He died in 1517, having been the first who practised the art of engraving in Italy. In this place we must not forget the master of so great a man as Leonardo da Vinci, Andrea Verocchio, a Florentine, born in 1432. He was well skilled in geometry, optics, music, architecture, sculpture, and painting; the last whereof he is said to have abandoned, because, in a picture whereon he was engaged of the baptism of our Saviour, his pupil, Leonardo, had, under his order, painted in an angel holding up some part of our Saviour's garment so far excelling Andrea's own figures that, enraged at being outdone by a youth, he resolved never again to wield the pencil. It is said he was the first who preserved individual likeness by moulding the face in plaster of Paris. Leonardo da Vinci, of noble descent, and born about 1445 in a castle so named near Florence, surpassed all his predecessors. His powers seem to have been unlimited: he was an admirable sculptor and architect, a skilful musician, an excellent poet, expert in anatomy and chemistry, and well versed in all parts of the mathematics. Rubens had a very high opinion of his works, and especially of his Cenacolo, in the refectory of the Dominicans at Milan, which "he abandoned without finishing the head of Christ, exhausted by a wild chase after models for the heads and hands of the apostles: had he been able to conceive the centre, the radii would have followed of course." He was many years director of the academy of painting at Milan, which city he much benefitted by his contrivance of the canal that supplies it with water from the river Adda. He had the honour of expiring in the arms of Francis I.—an honour by which destiny atoned to that monarch for his future disaster at Pavia, when he became a captive. His death took place in 1520. The last master of this period was Bartolomeo della Porta. Though not endowed with the comprehension of Leonardo, he first gave gradation to colour, form and masses to drapery, and dignity to execution. Fra Bartolomeo, as he was called, being a member of a religious order, was a native of Savignano, a village about ten miles from Florence, and was born in 1469. Nudities were scarcely ever represented by him, though he was a perfect master of drawing the human figure. He was the first who used the lay figure. Fuseli says of him, "He was the true master of Raphael, whom his tuition weaned from the meanness of Pietro Perugino, and prepared for the mighty style of Michael Angelo Buonaroti." Of this master, the greatest beyond comparison that ever appeared, we cannot refrain from again quoting the same author at considerable length, to which, if necessary, might be added the testimony of Sir Joshua Reynolds, whose parting wish, when he took leave of the Royal Academy, was that the last words he might pronounce within its walls might be the name of this wonder of mankind. "Sublimity of conception, grandeur of form, and breadth of manner, are the elements of Michael Angelo's style. By these principles, he selected or rejected the objects of imitation. As painter, as sculptor, as architect, he attempted, and, above any other man, succeeded, to unite magnificence of plan, and endless variety of subordinate parts, with the utmost simplicity and breadth. His line is uniformly grand; character and beauty were admitted only as far as they could be made subservient to grandeur. The child, the female, meanness, deformity, were by him indiscriminately stamped with grandeur. A beggar rose from his hand the patriarch of poverty; the hump of his dwarf is impressed with dignity; his women are moulds of generation; his infants teem with the man; his men are a race of giants." Again, "He is the inventor of epic painting, in that sublime circle of the Sistine Chapel, which exhibits the origin, the progress, and the final dispensations of theocracy." Michael Angelo was of noble family, and born at Castel Caprese, near Florence, in 1474. His master was Domenico Ghirlandaio. He died in great wealth, at Rome, in 1564; from thence his remains were removed to Florence, and there honourably interred. His principal disciples were Marcello Venusti, Il Rosso, Giorgio Vasari, and Fra Bastiano. Raphael Sanzio d'Urbino was born on Good Friday in the year 1483, and died on Good Friday in the year 1520. The grace and mild genius of Raphael were, perhaps, much more capable of exciting our sympathies than the burst of inspiration which the works of the last-named master universally exhibited. As Michael Angelo was the father of epic painting, so was Raphael that of dramatic painting. "If, separately taken, the line of Raphael has been excelled in correctness, elegance, and energy, his colour far surpassed in tone, and truth, and harmony; his masses in roundness, and his chiaro-oscuro in effect: considered as instruments of pathos, his pictures have never been equalled; and in composition, invention, expression, and the power of telling a story, he has never been approached." Giulio Romano was his greatest pupil. His conceptions were more extraordinary, more profound, and more elevated than even those of the master himself. His style was drier and harder than any of Raphael's school, and he was frequently harsh and ungraceful. He died at the age of fifty-four, in the year 1546.

Giorgio del Castel Franco, called, because of his size and beauty, Giorgione, and Tiziano Vecelli, combined to form the alluring and fascinating charm of colour. Born in the Venetian States, and in the same year, 1477, they laid the foundation of the Venetian school. Of the latter, our professor says, "he penetrated the essence and the general principle of the substances before him, and on these established his theory of colour. He invented that breadth of local tint which no imitation has attained; and first expressed the negative nature of shade: his are the charms of glazing, and the mystery of reflexes, by which he detached, rounded, connected, or enriched his objects. His harmony is less indebted to the force of light and shade, or the artifices of contrast, than to a due balance of colour, equally remote from monotony and spots. His backgrounds seem to be dictated by nature. Landscape, whether it be considered as the transcript of a spot, or the rich combination of congenial objects, or as the scene of a phenomenon, dates its origin from him: he is the father of portrait painting, of resemblance with form, character with dignity, and costume with subordination." Antonio Læti, or Allegri, called Correggio, from the place of his birth, in the duchy of Modena, completed the charms of colouring and chiaro-oscuro. Giulio Romano, when he saw the Leda and Venus he had painted for Frederic duke of Modena, declared he thought it impossible for colouring to be carried farther. His chief works are at Modena and Parma; at which last place he passed the greater portion of his life, and died at the age of forty, in the year 1534. Though the power of Correggio's colouring was great, still greater was that of his chiaro-oscuro. "The bland central light of a globe, imperceptibly gliding through lucid demi-tints into rich reflected shades, composes the spell of Correggio, and affects us with the soft emotions of a delicious dream." The merits of Raphael are pathos and character; the power of Titian was his colour, and of Correggio his harmony. We have not space to dwell on the lively genius of Pordinone, who disputed the superiority of Titian, the meagre style of Andrea Vannuchi, surnamed del Sarto, nor the extraordinary vigour and puerile imbecility of conception of Pellegrino Tibaldi; but we must not pass without notice the name of Sebastiano del Piombo, a Venetian, who died at the age of 62, in 1547. His name, Del Piombo, is derived from an office he held in the management of the lead mines, given him by pope Clement VII. For some time he practised the science of music, to which he was bred; but the fascinations of painting drew him aside from his original pursuit, and he became a disciple of old Gio-Ballino, continued his studies under Giorgione, and, having attained considerable perfection in colouring, went to Rome. Here he so ingratiated himself with Michael Angelo, by joining the party against Raphael, that he was assisted in his designs by that great master, and especially in that wonderful picture, now in the National Gallery here, of the Raising of Lazarus, which gained the universal applause of Rome, and was even put on a par with the celebrated picture of the Transfiguration by Raphael. Equally favoured by Michael Angelo was Daniel Ricciarelli of Volterra, in whose picture of Christ and the Women, in the Descent from the Cross, as well as in that of Sebastian's just mentioned, the master hand that directed them is manifest. The depravation of the style of Michael Angelo is sufficiently visible in the works of Giorgio Vasari, born at Arezzo in 1514, to whom the world is more indebted for the labours of his pen, in the History of the Lives of the most celebrated Painters, Sculptors, and Architects, first published at Florence, in 1550, than those of his pencil: him Fuseli describes as the most superficial artist, and the most abandoned mannerist of his time. "He overwhelmed the palaces of the Medici and of the popes, the convents and churches of Italy, with a deluge of mediocrity, commended by rapidity and shameless bravura of hand: he alone did more work than all the artists of Tuscany together; and to

him may be truly applied, what he had the insolence to say of Tintoretto, that he turned the art into a boy's toy." Felibien has taxed him with the flattery of the masters of his time, and partiality to those of his own country; but his work is nevertheless a valuable record of the lives of men to whom the world is much beholden; and contains many interesting anecdotes, which, but for him, would have been lost for ever. His death happened in 1578. Primaticcio, the scholar of Giulio Romano, made abbé of St. Martin de Troyes by Francis the First, studied and spread the style of his master in France, where he decorated the palaces of that king with mythology and allegory, in which he was assisted by his pupil, Nicolo del l'Abbate, an excellent artist. Primaticcio continued in France from the period of his first establishment there; lived in great pomp and state, more like a nobleman than a painter, through four several reigns, and died at the age of 80, in the year 1570. After Polidoro da Caravaggio, whose abilities were wasted on the representations of Roman military basso-relievos, the Roman school scarcely deserves notice till the appearance of Nicolas Poussin of Andilly, a town in Normandy, who was born in 1594. He was descended of a noble family of Picardy; but that his productions have shed a ray of lustre on the family which no nobility of blood could have effected, his designation by the name of the French Raphael sufficiently testifies. Nicolas was the disciple of Simon Varin, a French painter of mediocrity, and afterwards studied in the academy of Domenichino, and also in company with the famous sculptor Francesco Fiammingo, who was born in the same year, and bred in the same house with him. After a stay of more than 16 years in Rome, he was invited, by a letter under the hand of Louis XIII. himself, to return to his native country, where he was received with every honour, declared first painter to the king, and had a considerable pension conferred upon him. Upon the death of this king, and that of the cardinal Richelieu, he returned to Italy, to settle his affairs and return with his family; but, on his arrival in Rome, he entirely laid aside his intention of returning, and ended his days in Rome, at the age of 71 years. "Such was his attachment to the ancients, that it may be said he less imitated their spirit than copied their relics and painted sculpture. The costume, the mythology, the rites of antiquity, were his element; his scenery, his landscape, are pure classic ground. His eye, though impressed with the tint, and breadth, and imitation of Tiziano, seldom inspired him to charm with colour; crudity and patches frequently deform his effects." The mantle of Correggio seemed to have fallen on Parmegiano, though he possessed not the mode of expressing that expanse of harmony which no other eye than that of Correggio has conceived. Francesco Mazzuoli, called from Parma, the place of his birth, Parmegiano, was born in 1501, and died at the early age of thirty-six. "That disengaged play of delicate forms, the 'Sveltezza' of the Italians, is the prerogative of Parmegiano, though nearly always obtained at the expense of proportion. His grandeur, as conscious as his grace, sacrifices the motive to the mode, simplicity to contrast. His St. John loses the fervour of the apostle in the orator; his Moses the dignity of the lawgiver in the savage. With incredible force of chiaro-oscuro, he united bland effects and fascinating hues; but their frequent ruins teach the important lesson, that the mixtures which anticipate the beauties of time are big with the seeds of premature decay."

Towards the end of the sixteenth century, Lodovico Caracci, with his cousins Annibale and Agostino, founded a school at Bologna, in which it was proposed to select the beauties, correct the faults, supply the defects, and avoid the extremes of the different styles, and so attempt to form a perfect system. The recipe of ingredients for the formation of a perfect painter are contained in a sonnet by Agostino, well known to artists; they are as follows — Roman design, Venetian motion and shade, Lombardy's dignified tone of colour, the fierce style of Michael Angelo, Raphael's symmetry, Titian's truth to nature, and Correggio's sovereign purity: add to these the decorum and solidity of Tibaldi, the learned invention of Primaticcio, and a little of Parmegiano's grace; or, to save all this trouble, imitate the works of our dear Nicolo. This was empiricism unworthy of such men as the Caracci, whose talents were splendid, and of a very high order. Lodivoco was "the sworn pupil of nature." "Agostino, with a singular modesty, which prompted him rather to propagate the fame of others by his graver, than by steady exertion to rely on his own power for perpetuity of name, combined with some learning a cultivated taste, correctness though not elegance of form, and a Correggiesque colour." Annibal, whose taste was unequal to both of these, though his power of execution was far superior, was born at Bologna, in 1560, and was the disciple of his cousin Lodovico. His great work was the Farnese Palace, in which, whilst we admire the vigour of the execution, we cannot help lamenting the choice of subject, which is "a chaotic series of trite fable and bacchanalian revelry, without allegory, void of illusion, merely to gratify the puerile ostentation of dauntless execution and academic vigour." Such was the veneration of Annibal Caracci for the genius of Raphael, that his deathbed request was to be buried in the same tomb with him, which request was complied with, in the Pantheon at Rome, 1609. This eclectic Bolognese school did not last long; its scholars soon followed each his own peculiar taste. Its principal elèves were Schidone, Guido, Lanfranco, Albani, Zampieri, called Domenichino, and Francesco Barbieri, called Guercino. The merits of these are summed up as follows, by the admirable critic we have so often quoted in this article: — "Schidone, whose mind was in his eye, embraced and often applied the harmony and colour of Correggio; whilst Lanfranco strove without success to follow him through the expanse of his creation and masses. Grace attracted Guido, but it was the studied grace of theatres; his female forms are abstracts of antique beauty, attended by languishing attitudes, and arrayed by voluptuous fashions. His male forms, transcripts of models found in a genial climate, are sometimes characteristic of dignified manhood or apostolic fervour, sometimes stately, courteous, insipid." "His Aurora deserved to precede a more majestic Sun, and Hours less clumsy." His colour is occasionally bland and harmonious, sometimes vigorous, and sometimes insipid. Albani formed Nereids on plump Venetian models, and contrasted their pearly hues with the rosy tints of Loves, the juicy brown of fauns and satyrs of rich marine or sylvan scenery. Domenichino aimed at the beauty of the antique, the expression of Raphael, the vigour of Annibal Caracci, the colour of Lodovico; and, mixing something of each, fell short of all: whilst Guercino broke through all academic rules, sacrificing mind, form, and costume to effects of colour, fierceness of chiaro-oscuro, and intrepidity of hand. From this period the art declined rapidly in Italy: it was, indeed, held up for a short period by the exertions of Nicolas Poussin, of whom we have already spoken. Pietro da Cortona and Luca Giordano possessed very considerable talents; but they were much abused in their exercise by implicit obedience to the tasteless commissions of their employers.

Germany, though without much apparent intercourse at the time with Italy, had profited by the progress of the arts; therefore, towards the end of the fifteenth century, we find the works of Albert Durer had succeeded the rude and uncouth productions of Schön, Wolgemuth, and Altorfer. Albert Durer was born at Nuremberg on Good Friday, 1471. Notwithstanding his style was crude and ungraceful, his prints were esteemed throughout Italy, copied at Venice by the celebrated Marc Antonio, and so much admired by even Raphael himself that he decorated his own chamber with them, and often lamented that such a man had been educated in a country where the want of models and works of art must have so retarded his progress. His principal works were painted at Prague, for the Emperor Maximilian I. He died in 1528. Fuseli says of him, "Albert Durer was, in my opinion, a man of great ingenuity, without being a genius. He studied, and, as far as his penetration reached, established certain proportions of the human frame, but he did not invent a style: every work of his is a proof that he wanted the power of invention, of concluding from what he saw to what he did not see; that he copied rather than selected the forms that surrounded him, and, sans remorse, tacked deformity and meagreness to fulness, and sometimes to beauty." Lucas of Leyden was but a clumsy imitator of Albert. Aldegraver, Beheim, and George Pentz, from the study of Raphael, known to them through the medium of Marc Antonio's prints, and from the style of Michael Angelo, distilled through prints from Tibaldi's pictures, seem to have made some advances in the art. The knowledge, however, of its state in Italy attracted hosts of German, Dutch, and Flemish students, who, "though content to feed on the husks of Tuscan design, imbibed the colour of Venice, and spread the elements of that excellence which distinguished the succeeding schools of Flanders and of Holland."

Peter Paul Rubens, born in Cologne in 1578, and Rembrandt Van Rhyn, born near Leyden in 1606, by their extraordinary powers showed that Italy was not the only spot in which art could take root, but that Flanders and Holland afforded a soil in which it could flourish. The former of these, bred at Antwerp under the instruction of Otho Van Veen, had, previous to his journey to Italy, acquired an unbounded power over the instruments of his art, and on his arrival was the successful competitor for fame with those masters whom he selected as objects of emulation. Venice was the centre of attraction for him; and there, from the splendour of Paulo Veronese, and the glow of Tintoretto, he compounded "that florid system of mannered magnificence which is the element of his art, and the principle of his school." His scholars saw through the eye of their master instead of seeing through that of nature; but from this censure must be excluded the illustrious name of Van-

dyck, and that of Abraham Diepenbeck. Of the portraits of Vandyck no mention is here necessary to enhance the esteem in which they are held. "The fancy of Diepenbeck, though not so exuberant, excelled in sublimity the imagination of Rubens; his Bellerophon, Hippolitus, Ixion, Sisyphus, fear no competitor among the productions of his master." Rembrandt, except in what relates to form, was a genius of the highest order. "In spite of the most portentous deformity, and without considering the spell of his chiaro-oscuro, such were his powers of nature, such the grandeur, pathos, or simplicity of his composition, from the most elevated or extensive arrangement to the meanest and most homely, that the best cultivated eye, the purest sensibility, and the most refined taste dwell on them equally enthralled." His followers, if such they deserve to be called, were a race of "colourists, content to tip the cottage, the hamlet, the boor, the ale-pot, the shambles, and the haze of winter with orient hues or the glow of setting summer suns."

Switzerland rests its title to distinction on the names of Hans Holbein and Francesco Mola; the former of Basil, born in 1498, died in London at the age of 46; the latter, the scholar of Giuseppe d'Artino and Francesco Albani, was born at the village of Coldré in 1621, and died in Rome in 1666. The Swiss school exhibited a style poised between the emaciated dryness of Albert Durer and the bloated corpulence of Goltzius.

The school of the Caracci seems to have taken its deepest root in France, which, with few exceptions, has not produced artists greatly above mediocrity. The exceptions, however, which are to be named are, Nicolas Poussin, who has already been mentioned: to this must be added those of Eustache Le Sueur, Charles Le Brun, Sebastian Bourdon, and Pierre Mignard. "The Seven Works of Charity, by S. Bourdon, teem with surprisingly pathetic and always novel images; and in the Plague of David, by Pierre Mignard, our sympathy is roused by energies of terror and combinations of woe which escaped Poussin and Raphael himself."

From what cause may be difficult to say, but the labours of the Spanish school were confined almost within the narrow limits of individual imitation. The degree of perfection in this respect was indeed great, though the means pursued were very different; and the works of Diego Velasquez, Joseph Ribera, and Murillo, though never approaching the great style of art, impress us with respect for their powers, and deservedly received the homage of the Spanish nation.

In this country, Henry VIII. was the first monarch who seems to have taken any interest in the art. He invited Titian to England, and patronised Holbein and Torregiano. But this patronage, very unlike that bestowed by Francis I. on Andrea del Sarto, Primaticcio, Nicola, Cellini, and others, was so restricted in the choice of subjects, that neither Henry nor his daughter Elizabeth deserve our veneration for the assistance they rendered to the arts of the country. In the court of Henry's father a profligate Flemish painter, of the name of Mabuse, had indeed been employed; but it is not known whether he came here at that king's solicitation or driven by his own distresses. The pencil of Holbein, among its other employments, was of course employed to portray the beauties of Henry's wives, or of those he intended to make so: sometimes, indeed, to obtain a just report of the latter he was despatched to the Continent; and in the case of Anne of Cleves, through his faithless pencil Cromwell, the minister, lost his head. If painting was at this period likely to have taken root and flourished here, the Reformation, and the worse than absurd edicts passed by Edward VI. and Elizabeth, forbidding statues and pictures in churches, were nipping frosts that destroyed its growth. Charles was the first real patron of the arts that governed this country. By him was Rubens invited to the country; but the unfortunate fate of the monarch intercepted the progress that art then seemed likely to make. "His son, in possession of the cartoons of Raphael, and with the magnificence of Whitehall before his eyes, suffered Verrio to contaminate the walls of his palaces, or degraded Lely to paint the Cymons and Iphigenias of his court; whilst the manner of Kneller swept away completely what yet might be left of taste under his successors." The state of art continued extremely low in this country till the appearance of Reynolds. Walpole says that in the commencement of the reign of George I. the arts of England were sunk almost to the lowest ebb. The names of Reynolds, Hogarth, Gainsborough, and Wilson, in their time, entitled this nation to some rank in the art; though we have as yet had no indication of that great style of art whose history has occupied a considerable portion of the preceding pages. The names we have mentioned have been succeeded by others, and some now living, which have, perhaps, not only prevented the accusation of a retrograde movement, but have raised the art generally in the country higher than it was ever known in a preceding period—yet much remains to be done. The genius of the nation seems bound up in commerce and politics; total ignorance of the first principles of art seems still to pervade those who only are capable of affording patronage; and many a collector, on whose walls hang the most splendid specimens of the Roman and Florentine schools, must, if he will speak the truth, admit that his admiration of the tobacco pipes, pewter pots, and vulgar boors of the Dutch school, a school of low ideas and good painting, is more profound than of the sublime conceptions of Raphael and Michael Angelo.

Practice of Painting.— The nature of this work precludes a very enlarged notice of the theory and practice of painting: we shall, however, subjoin a few leading observations on the subject. One of the principal requisites for its successful practice is *anatomy*. It is obvious that to represent successfully the human form its construction in the skeleton, and the tendons and muscles by which the bones of the skeleton are connected and move, is knowledge that must be acquired, inasmuch as they appear more or less through the integuments with which they are covered. Without this knowledge the living model becomes useless to him; for that, after a very short period of standing, sinks into languor, which an acquaintance with the origin and insertion of muscles enables the painter to correct, and thus animate the work. It was the constant observation of the youth in their gymnastic games that enabled the Grecians so successfully to display and develop the muscular system in their sculpture: these afforded models of the most perfect nature. *Comparative anatomy* is another of the requisites to be acquired by the artist; since the painting of animals must necessarily involve a want of the same information as is requisite for the human figure. *Symmetry*, which results from the relative proportion of the parts to each other, follows from the knowledge of anatomy. It is by the knowledge of this that the length of a finger may be made to measure the height of a figure. Without the most thorough acquaintance of the rules of *perspective*, no objects can be placed properly in a picture. Some have said that though it is a science of the first importance to a painter, yet he is not to be too strictly confined to its rules, but to endeavour to render them subservient to his own purposes. We confess that such is not our opinion; nor can we conceive how any violation of truth, which any infraction of the rules of perspective would be, can be made agreeable in a picture. The rules, too, of perspective are so simple, and their practice so easily acquired, that no excuse can be admitted for the neglect of so indispensable an accomplishment. The science of *optics* is so far necessary as to enable the artist to determine how the reflexes against the sides of surfaces in shade would affect the intensity of them. This is called chiaro-oscuro. The determination of shadows, and the direction in which they would fall, depends upon the science of optics combined with that of perspective. As perfect form is produced by leaving out peculiarities, and retaining only general ideas, so this principle, extended in the other branches of the art, gives what is called the grand style to invention, to composition, to expression, and even to colouring and drapery. *Invention* in painting is not the same as in poetry, inasmuch as that the subject is supplied by the poet or historian. The subject should be general, and kept free from all that might tend to embarrass or divide the attention of the spectator. "Whenever," observes Sir Joshua Reynolds, in his Fourth Discourse, "a story is related, every man forms a picture in his mind of the action and expression of the persons employed. The power of representing this mental picture on canvass is what we call invention in a painter; and as in the conception of this ideal picture the mind does not enter into the minute particularities of the dress, furniture, or scene of action, so, when the painter comes to represent it, he contrives those little necessary concomitant circumstances in such a manner that they shall strike the spectator no more than they did himself in his first conception of the story." The painter may deviate from strict historical truth in pursuing the grandeur of his design, such being but poetical licence. "A painter of portraits retains the individual likeness; a painter of history shows the man by showing his actions. He has but one sentence to utter, but one moment to exhibit." *Expression*, which in painting signifies the representation of the emotions and passions of the mind, must, like invention, not descend to peculiarities. Thus Bernini, in representing David casting the stone from his sling, mistook accident for generality when he made him bite his under lip. *Colouring*, also, has its laws, and in this the same general principle must be attended to. "All trifling or artful play of little lights, or an attention to a variety of tints, is to be avoided; a quietness and simplicity must reign over the whole work, to which a breadth of uniform and simple colour will very much contribute. Grandeur of effect is produced by two different ways, which seem entirely opposed to each other. One is by reducing the colours to little more than chiaro-oscuro, which was often the practice of the Bolognese schools; and the other by making the colours very distinct and forcible, such as we

see in those of Rome and Florence; but still the presiding principle of both those manners is simplicity." *Drapery*, again, is managed by the same general laws: minute attention to the minor details of drapery injure the general effect; the folds should communicate easily, and be so cast as to have the appearance of accident; they must also be so contrived as to give the greatest effect to the figure. Artifice is as much as possible to be avoided.

Annibal Caracci considered twelve figures sufficient for any story; more than that, he thought, could only be employed to fill up space, or, as he expressed himself, they would be figures to be let.

Painting is divided into twelve branches, which their names sufficiently explain; viz. history, which comprises mystery and allegory; grotesque, such as the celebrated Loggia at the Vatican; portrait, fancy, animals, fruits and flowers, battle pieces, landscape, sea views; still life, which comprises all inanimate objects, but is chiefly applied to household furniture, and instruments and architecture.

PAI'RING. In Parliamentary language, that practice by which two members of the House of Commons, of opposite political opinions, agree to absent themselves from divisions of the house during a stated period. *See* PARLIAMENT.

PA'LACE. (Lat. palatium, whose etymology is not precisely ascertained.) In Architecture, a word generally used to denote the residence of kings and princes. On the Continent, however, the term is used with a much more extended signification; and even in this country the residences of bishops, and of some noblemen, are so called.

PA'LACE COURT. A court of justice erected by Charles I., and made a court of record, with power to try personal actions between party and party within a liberty extending to the distance of twelve miles round Whitehall. The judges are the steward of the king's household and knight-marshal for the time being, and the steward of the court or his deputy.

PA'LADIN. In the Romances of the Middle Ages, a term derived from the Roman Palatinus (from palatium, *a palace*), having its origin in the customs of the Byzantine court, by which the officers of the palace (palatini, comites palatii) were regarded as the highest dignitaries of the country; hence palasin, or paladin, in the early French romances, for a lord or chieftain; and the name was thence appropriated by the Italian romantic poets to the heroes of their legends, the warriors of Charlemagne.

PALÆO'GRAPHY. (Gr. πάλαιος, *ancient*, and γεάφω, *I write*.) The science or art of deciphering ancient inscriptions, including the knowledge of the various characters used at different periods by the writers and sculptors of different nations and languages, their usual abbreviations, initials, &c. The science termed diplomatics is, in effect, a branch of palæography. (*See* DIPLOMATICS.) Among many other modern authorities on this subject, the reader may be referred to Mr. Ottley's remarkable paper in the *Archæologia*, vol. xxvi., on an ancient MS. of Aratus; Champollion, *Traité d'Archéologie;* the publications of the Ecole des Chartes, under the directions of M. Champollion, at the Royal Library at Paris; Kopp, *Bilder und Schriften der Vorzeit*, 1819; *Palæo-Critica*, 1817. The most valuable compilation of palæographical knowledge is to be found in the *Traité de Diplomatique* of the Benedictines of St. Maur, 6 vols. 4to. 1748. See also *Maffei*, *Istoria Diplomatica*, 1727; Trombelli, *Arte di Conoscere l'Età de' Codici*, 1778. But, as Mr. Ottley truly observes, "nothing is more fallacious than the idea of being able to determine the ages of ancient inscriptions from the particular forms of their characters; and it is mere folly upon such grounds to attempt to build any solid argument."

PALÆONTO'LOGY. (Gr. παλαιος; ον, *being;* λογος, *a discourse*.) The branch of zoological science which treats of fossil organic remains.

PALÆOTHE'RIUM. (Gr. παλαιὸς, and θηριον, *beast*.) The name of a genus of extinct Pachyderms. It was characterized by having twenty-eight complex molar teeth, four canines, and twelve incisors, four in each jaw. Cuvier concludes that the palæotheres, like the tapirs, had also a short fleshy proboscis. Their remains characterize the gypsum quarries belonging to the eocene tertiary formations near Paris. They have also been found in the corresponding strata of the Isle of Wight. About twelve species of this extinct genus are already known.

PALÆ'STRA. (Gr. παλαιστρα.) Properly, a wrestling place or school (παλη, *wrestling*); and hence the place where public games of strength were performed, and, by metaphor, such games themselves (*studium palæstræ*, Horace). In Architecture, the palæstra was a part of the gymnasium (see *Pausan.* vi. 21. 2., and 23. 4.), especially appropriated to the athletes. The art of wrestling was termed palæstricè (παλαιστριχη).

PALANQUI'N. A sort of chair or chaise used by the Chinese, and in most parts of the East, as a vehicle of conveyance from one place to another. They are furnished with cushions and curtains; many of them are fitted up in the most costly style, and are usually borne by eight men, who relieve each other at intervals.

PA'LATALS. (Lat. palatum, *the palate*.) The letters *d*, *g*, soft and hard, *j*, *k*, *l*, *n*, and *q*, are so called, from the organ chiefly employed in their pronunciation.

PA'LATE. (Lat. palatum.) In Anatomy, the roof of the mouth. That part which is formed by the lower portions of the superior maxillary and palatine bones is called the "hard palate;" that which is due to the extension of membranous and muscular substance unsupported by bone is termed the "soft palate." In Zoology, the modifications of the bony palate, and the "palatal ridges," and other inequalties of the soft parts, are of use in the discrimination of the species of Mammalia.

PALATE, in a flower, is the convex base of the lower lip of a personate corolla.

PALA'TINATE. The name formerly given to two states of Germany, which were designated, by way of distinction, the Upper and Lower Palatinate, and, though not contiguous, were under the control of the same sovereign till 1620. At that period they underwent great changes, which it would be out of place here to indicate; but since the wars of the first French revolution, which contributed more than any event on record to unsettle the ancient landmarks, they have been divided among different German sovereigns, and their very name has disappeared from the maps of Germany. The word Palatinate is of feudal origin, and signifies, in a more restricted sense, the province or seigniory of a palatine; *i. e.* of a high dignitary during the middle ages, who originally held office in the court of the sovereign, and was designated the *comes palatii*, but who afterwards obtained the privilege of exercising the same power, rank, and jurisdiction, within his own province or district, as the comes palatii exercised in the palace.

PALATINE, COUNTY. *See* COUNTY.

PALATO-PHARYNGEUS. A muscle which arises at the root of the uvula and soft palate, and is inserted into the upper and back part of the thyroid cartilage; it draws the uvula and soft palate downwards and backwards, and pulls the thyroid cartilage and pharynx upwards.

PALE. (Lat. palus, *a stake*.) In Heraldry, the first and simplest kind of ordinary. It is bounded by two vertical lines, at equal distances from the sides of the escutcheon, of which it encloses one third. It seldom contains more than three charges. The *pallet*, when borne by itself, is one half of the pale; but sometimes as many as three pallets are borne together. A coat bisected by a vertical line, with a different field on each side of it, is said to be *party* (or divided) *per pale*. The pale is a very ancient and honourable bearing.

PALE, WITHIN THE. An expression well known in Irish history, applied to that portion of Ireland to which for some centuries after its invasion by the English, under Henry II. in 1172, the dominion of the latter was confined. The limits of the *pale* seldom extended beyond the modern province of Leinster, and were frequently much less considerable. (*Statistics of the British Empire*, vol. i. p. 429.)

PA'LEÆ. (Lat. palea, *chaff*.) A name given to the bracts that are stationed upon the receptacle of Compositæ between the florets, and having generally a membranous texture and no colour; also the interior bracts of the flowers of grasses.

PA'LES. The Italian goddess presiding over cattle, who was worshipped with great solemnity. Her festivals, called *Palilia*, were celebrated on the 21st of April, the day upon which, according to tradition, the foundations of Rome were laid by Romulus — the dies natalis urbis Romæ — as a great rustic holiday. On this day the shepherds purified their flocks by making them pass round a great fire made of laurel, pine, and olive branches, sprinkled with sulphur. An offering of wine, milk, and millet was then placed on the altar of the goddess, who was entreated to bless the earth and the flocks with fecundity, and to avert injury from them both. The term *palilia* is frequently written *parilia* in the ancient MSS.; but no doubt can be entertained as to the correctness of the former.

PALE'TTE. (Fr.) In Painting, the light board held by a painter while at work, on which the colours are arranged in their various tints.

PA'LFREY. A word seldom used, except in novels and romances to signify a small or gentle horse, such as is fit for a lady's use. It is also used by the old poetical writers for a horse used by kings or noblemen, or on state occasions.

PALI'CI. In Grecian Mythology, twin divinities, worshipped in Sicily, and especially in the neighbourhood of Etna; sons, according to some, of Jupiter and Thalia, the daughter of Vulcan; according to others, of Vulcan and Ætna, daughter of Ocean. Their heads appear on coins of Catania. Their name is said to be derived from returning (παλιν ἱκεσθαι) out of the earth, under which

their mother had borne them. (*Æschyl. Ætna*, apud *Macrob. Saturn*, v. 19.) Their celebrated Sicilian temple is mentioned by Virgil: —

> Pinguis ubi et placabilis ara Palici. *Æn.* ix. 585.

PALI'LLOGY, or PALILOGY. (Gr. παλιν, *again*, and λεγω, *I speak.*) In Rhetoric, the repetition of a word, or fragment of a sentence, for the sake of greater energy: also, epanalepsis and epizeuxis. Thus, Cicero (*pro Cæc.* ix. 24.), "Ferro, inquit, ferro, te rejeci;" "The living, the living, shall praise thee" (Psalms). A peculiar species of palilogy, also called *deuterologia*, or *anadiplosis*, is where the last word of a verse, or of a paragraph in prose, is repeated at the beginning of the next: —

> ——supervenit Ægle—
> Ægle naiadum pulcherrima. *Virg. Eclog.* vi. 20.
>
> ——the innocent sleep —
> Sleep that knits up the ravell'd brow of care. *Macbeth.*

PA'LIMPSEST. (Gr. παλιν, *again*, and ψαω, *I rub or efface.*) The name given to a sort of parchment, from which whatever was written thereon might be erased, so as to admit of its being written on anew. The term means literally *twice-rubbed* (*membrana iterum abrasa, charta deletilis*), not as the glossary of Ducange would seem to denote, because the parchment had twice undergone erasure, or the writing been twice obliterated; but because it had been twice prepared for writing, which was principally effected by rubbing it with pumice, first in the course of manufacture after the skin had been cured, and again by the same process after the original writing had been taken away by washing or in any other manner. The strict and precise sense of *palimpsest* is, therefore, "twice prepared for writing;" the repetition of such preparation being the prevailing idea in the etymology, and not erasure, as some have erroneously supposed. The great antiquity of the practice of making palimpsests may be gathered from an extract from a letter from Cicero to Trebatius: — "Ut ad epistolas tuas redeam, cætera belle, &c.; nam quod in palimpsesto, laudo equidem parsimoniam; sed miror quid in illa chartula fuerit, quod delere malueris quam hæc non scribere; nisi forte tuas formulas. Non enim puto te meas epistolas delere, ut reponas tuas. An hoc significas, nihil fieri? Frigere te? Ne chartam quidem tibi suppeditare?" (*Cic. ad Fam.*, l. 7. c. 18.) But while there can be no doubt as to the antiquity of this practice, the attention of the learned was first directed to the subject in modern times by Montfaucon, in a curious essay entitled *Dissertation sur la Plante appellée Papyrus, &c.*, which appeared in the *Mem. de l'Acad. Fran.*, vol. vi.; and in which the origin of the Palimpsest MSS. is briefly and plainly described in the following words: —

"Cela (le papier bombycin) vint fort â propos dans un temps, où il paroit qu'il y avoit grande disette de parchemin; ce qui nous a fait perdre plusieurs anciens auteurs: voicy comment. Depuis le 12e siècle, les Grecs, plongez dans l'ignorance, s'avisèrent de racler les écritures des anciens MSS. en parchemin, et d'en ôter, autant qu'ils pouvoient, toutes les traces, pour y écrire des livres d'Eglise: ce fut ainsi qu'au grand préjudice de la république des lettres, les Polybes, les Dions, les Diodores de Sicile, et d'autres auteurs que nous n'avons plus, furent métamorphosez en Triodions, en Pentecostaires, en Homélies, et en d'autres livres d'Eglise. Après une exacte recherche, je puis assurer que des livres écrits sur du parchemin depuis le 12e siècle, j'en ay plus trouvé dont on avoit raclé l'ancienne écriture, que d'autres. Mais comme tous les copistes n'estoient pas également habiles â effacer ainsi ces premiers auteurs, il s'en trouve quelques-uns où l'on peut lire au moins une partie de ce qu'on avoit voulu raturer."

We have already seen that the practice of which Montfaucon speaks had a much more ancient date than that which he assigned to it; although it was in all probability most frequent during the middle ages, when, in consequence of the scarcity and expense of parchment, and the growing demand for the writings of the fathers and of books of devotion, the monks were induced to efface the writings of the ancient authors to make room for their own. Our limits preclude us from entering at length into the means adopted by the monks of effacing the original writing, or of that still more interesting process by which in recent times the original writing has been again brought to light, and which has thus put us in possession of some most valuable works and fragments of the classic authors which had been given up as lost. On these points we beg to refer the reader to an able article in the *Edin. Rev.* vol. xlviii., in which all that has been done in the restoration of ancient MSS. is set forth with great clearness and brevity; and shall content ourselves with observing, that the most important of these discoveries are the treatise of Cicero, *De Republica*, which was found in the Vatican library at Rome, in a MS. which had been rewritten, with a Commentary of St. Augustin on the Psalms; and the *Institutions of Gaius*, found also in the same place. For the restitution of the former the learned world is indebted to Angelo Maio, the principal librarian of the Vatican library at Rome, who may indeed be regarded as the hero of palimpsests; and for the latter to the labours of Bluhm and Goeschen, who were sent to Rome for the purpose of examining MSS. by the Royal Academy of Sciences at Berlin.

PALI'NDROMUS. (Gr. παλιν, and δρομος, *a course.*) A verse or line which was the same when read backwards or forwards. The well-known verse which has been put into the mouth of the devil may serve for an example: —

> Signa te, signa, temere me tangis et angis.

PALINGENE'SIA. (Gr. παλιν, and γενεσις, *birth.*) In Philosophy, a new or second birth—regeneration. The doctrine of the destruction and reproduction of worlds and living beings is oriental; but the word in question appears to be of Stoical origin. (*Diog. Laert.* vii. 72.) The Stoics are said to have held that the demiurgus, or creator, had absorbed all being in himself, and reproduced it out of himself. In the language of the New Testament, it is used for moral regeneration. (Titus, iii. 5.)

PA'LINODE. (Gr. παλιν, *again*, and ῳδη, *song.*) In Poetry, a recantation: properly, a piece in which the poet retracts the invectives contained in a former satire. (See *Mem. de l'Acad. des Inscr.* vol. xii.)

PALINU'RUS. The steersman of the vessel of Æneas, drowned, according to Virgil, off the coast of Italy (*Æn.* v.), and afterwards met with by the Trojan hero in the shades. A promontory on the coast received his name.

PA'LISADES, or PALISADOS. In Fortification, stakes driven into the ground, and sharpened at the top, for the purpose of defence against the surprise of an enemy. They are usually 9 or 10 feet long, and planted so as to make an angle inclining outwards from the work.

PA'LLA. In Latin, the long outer garment appropriate to Roman females of respectable rank. A part of it was thrown over the left shoulder, and hung down from the arm. It is particularly described by Apuleius. (*Met.* xi.) The palla was not worn by men, except some effeminate persons; although the long robes of barbarians are sometimes called by its name by Latin writers. There seems to have been a shorter palla. (*Martial*, i. 93.)

PALLA'DIUM. (Gr. Παλλάδιον.) A wooden statue of Minerva or Pallas, which was said to have fallen from the skies, as a sign to Ilus, the founder of Troy, to convince him he was under the guidance of Jupiter. On its preservation depended the safety of Troy; and, accordingly, Ulysses and Diomed were commissioned to steal it, and performed the enterprise. According to other accounts, the palladium was conveyed from Troy to Italy by Æneas, and was afterwards preserved with great care in the temple of Vesta at Rome. The word palladium passed into European languages, in which it signifies that particular law or privilege which is regarded as the safeguard of the people's liberties. The trial by jury, and the freedom of the press, are each called the *palladium* of the British constitution.

Palladium. A metal discovered in 1803 by Wollaston, associated with the ore of *platinum*. It resembles platinum in colour and lustre, and it is ductile and malleable, but very hard. Its specific gravity is 11·8. Its fusibility is intermediate between gold and platinum; it is oxidized and dissolved by nitric acid: its oxide forms red salts.

PA'LLAS, or more properly PALLAS ATHE'NE. In Mythology, the Grecian goddess of wisdom, identified at a later period with the Roman Minerva, to whom were assigned all the attributes of her Grecian sister. The term is probably derived from the Gr. παλλειν, *to brandish a spear.* *See* Minerva.

Pallas. One of the four small planets which revolve between the orbits of Mars and Jupiter, discovered by Dr. Olbers, of Bremen, on the 28th of March, 1802. Its symbol is a lance ⚴. On account of the minuteness of this planet, and the nebulous appearance by which it is surrounded, it is extremely difficult to arrive at any certain conclusion respecting its real magnitude. Sir W. Herschel estimated its diameter at eighty miles, and Schroeter at 2099 miles, or nearly the size of Mercury; but astronomers prefer the former measure. The light of the planet undergoes considerable variations, the cause of which is unknown. The following are the elements of the orbit given by Encke, in the Berlin *Astronomisches Jahrbuch* for 1831: —

Semi-axis major $= 2{\cdot}77263$
Eccentricity $= 0{\cdot}24199$
Period of revolution $= 1686{\cdot}25$ days
Inclination $= 34^\circ\ 35'\ 49''{\cdot}1$
Longitude of ascending node $= 172^\circ\ 38'\ 29''{\cdot}8$
Longitude of perihelion $= 121^\circ\ 5'\ 0''{\cdot}5$.

The motion of the planet in its obit is greatly disturbed by the powerful attraction of Jupiter. *See* Planet.

PA'LLETS, in Clock and Watch-work, are the pieces connected with the pendulum or balance which receive

the immediate impulse of the swing-wheel, or balance-wheel. They are of various forms and constructions, according to the kind of escapement employed.

PALLIOBRA'NCHIATES, *Palliobranchiata.* (Lat. pallium, *a mantle*, and branchia, *gills.*) The name of an order of Acephalous Mollusks, including those in which the gills are situated on the internal surface of the lobes of the mantle.

PA'LLIUM. (Lat. *a cloak.*) A vestment which, by ancient usage, is sent from Rome to all archbishops of the Roman Catholic church, and to the four Latin patriarchs of the East, on their accession. The history of this usage, and the gradual submission of the Western patriarchs to it, thereby acknowledging in the end the complete authority of the see of Rome, is carefully traced by M. Rheinwald, in the new *Encyclopædia* of Ersch and Gruber, art. "Pallium." It is now a short white cloak, with a red cross, encircling the neck and shoulders, and falling on the back. It was the custom, at the period of the greatest power of the Roman see (introduced by Gregory VII. himself), for the archbishops to come to Rome for the purpose of receiving it: it is now delivered as a mandatory, or merely by a delegate from Rome. Some simple bishops receive the pallium as a mark of honour. The cloth of which the pallium is made is woven from the wool of ten white lambs, blessed at Rome on the festival of St. Agnes, and deposited on the tomb of St. Peter during the eve of his festival.

PALM. (Lat. palma, *the hand.*) An ancient measure of length taken from the extent of the hand. There were two different palms; one corresponding to the length of the hand, and the other to the breadth. The Roman palm was about 8¼ English inches. The English palm is understood to be 3 inches.

PALMA'RES. (Lat. palma, *the hand.*) Muscles belonging to the hand. The *palmaris brevis* is situate between the wrist and little finger, and assists in contracting the palm of the hand; the *palmaris longus* is situate on the forearm, and bends the hand.

PA'LMER. In Ecclesiastical History, a name popularly given to crusaders returned from the holy war, or pilgrims from Palestine, from the branch of palm-tree which they were wont to carry with them as a staff in commemoration of their journey.

PA'LMIPEDS, *Palmipedes.* (Lat. palma, *a palm,* and pes, *a foot.*) The name given by Cuvier and Temminck to an order of birds corresponding to the *Anseres* of Linnæus, and the *Natatores*, or swimming-birds, of Illiger.

PA'LMISTRY. (Lat. palma, *the hand.*) A species of divination, which foretold future events from the inspection of the lines and marks on the hands and fingers. *See* CHIROMANCY.

PALM OIL. An article imported from the west coast of Africa: it is solid, and of a reddish-yellow colour. It is used in the manufacture of soap: candles have been made of its stearine, and it is sometimes burned in lamps, and made into ointments. It is chiefly the produce of the *Elæius Guinænsis.*

PALM, ORDER OF THE FRUITFUL. A society formed in 1617 in Germany, and connected by a species of chivalrous institution, for the preservation and culture of the German language. Lewis, prince of Anhalt, was the first head of the order. This body is said to have done much for the German language, but to have ended by attempting too much in the way of refinement and innovation. It was dissolved in 1680. (*Ersch and Gruber's Encyclopædia.*)

PALMS, called by Linnæus, from their noble and stately appearance, the princes of the vegetable kingdom, are a natural order of Arborescent Endogens, chiefly inhabiting the tropics, distinguished by their fleshy, colourless, six-parted flowers, enclosed within spathes; their minute embryo, lying in the midst of albumen, and remote from the hilum; and rigid plaited or pinnated inarticulated leaves, sometimes called fronds. Wine, oil, flax, flour, sugar, and salt, says Humboldt, are the produce of this tribe; to which Von Martius adds thread, utensils, weapons, food, and habitations. The most common species is the cocoa-nut. Their wounded stems, or spathes, yield in abundance a saccharine fluid, known in India by the name of toddy. The succulent rind of the date is a most nutritious as well as agreeable fruit. Sago is yielded by the interior of the trunks of nearly all, except *Areca catechu*, the well-known *pisang*, or betel-nut: the fruit of the latter species is remarkable for its narcotic or intoxicating power. The common canes or rattans of the shops are the flexible stems of species of the genus *Calamus.*

PALM-SUNDAY (Dominica Palmarum, Pascha Floridum), the Sunday before Easter, is the day of celebration of the triumphal entry of Christ into Jerusalem. But the custom of carrying palm branches on particular days of festivity (βαιοφορια) was an older Jewish observance. The feast of Palm Sunday appears to have been observed all along in the Eastern church, but is said to have been revived in the West by Gregory the Great. The earliest known Latin homily for the day is by the Venerable Bede.

PALP. (Lat. palpus, *a feeler.*) A jointed sensiferous organ, attached in pairs to the *labium* and *maxilla* of insects, and termed respectively "labial" and "maxillary" palpi, or feelers.

PALPA'TORS, *Palpatores.* The name of a family of Clavicorn beetles, including those which have very long maxillary feelers, or palps.

PALSY. *See* PARALYSIS.

PALU'DAME'NTUM. The peculiar military dress of a Roman general (imperator), in the times of the republic (*Apul. Apologia*), afterwards adopted by the emperors. It was worn only in the campaign, and exchanged for the toga in Rome. Vitellius, according to Tacitus, was advised not to enter the city in it, as it would be making it look like a city taken by storm. (*Hist.* ii. 89. See *Mem. de l'Acad. des Inscr.* vol. xxi.)

PALUDI'NA. (Lat. palus, *a marsh.*) A genus of fresh-water or marsh snails; so called from their location in marshes, ditches, and slow streams. Many species are common in Great Britain; a beautiful example, called the agate marsh-shell (*Paludina achatina*, Lam.), may be found in the smaller tributaries of the Thames.

PA'MPAS. The name given to one of the great systems of South American plains, which can scarcely with propriety be called *deserts*, inasmuch as they are covered with luxuriant herbage, and inhabited by vast herds of wild cattle and droves of horses. The region of the Pampas forms the basins of the Paraguay and La Plata, and includes the vast plains of Buenos Ayres, extending from the foot of the eastern ridge of the Andes to the "sea-like Plata," and stretching southward into the deserts of Patagonia. (*Traill's Physical Geography.*)

PA'MPHLET. A word for which various etymologies have been suggested; as, for instance, pagina filata, *a threaded page*, i.e. leaves stitched together with a thread; while others consider it to be derived simply from pampier, or papier, *paper.* It signifies a short treatise or essay, generally speaking on some subjects of temporary interest, which excites public attention at the time of its appearance. We commonly understand by the word pamphlet a production of the above character when it comes from the publishers merely stitched together in sheets, and not bound. The word is of considerable antiquity, being used by Chaucer. Pamphlets became of common use in political and religious controversy about the middle of the 16th century; in England, under the reign of Elizabeth; in France, during the wars of religion.

PA'MPRE. (Fr.; from Lat. pampinus, *a cluster.*) In Sculpture, ornaments consisting of vine leaves and grapes.

PAN. (Gr. Πάν.) The chief rural divinity of the Greeks, who presided over flocks and herds. He was said by some to be the son of Mercury; and his birthplace was Arcadia, to which province his worship seems to have been confined in early times. The introduction of his worship into the other Grecian states is thus accounted for. When Philippides, an Athenian courtier, was traversing Mount Parthenius, above Tegea, a short time before the battle of Marathon, he was encountered by Pan, who commanded him to ask the Athenians why they paid no respect to a divinity who had ever been friendly to them, and was still ready to promote their welfare; and in consequence of this remonstrance the Athenians, after the defeat of the Persians, dedicated a temple to this divinity beneath the Acropolis, and propitiated his favour by annual sacrifices and torch races. He was represented with the head and breast of an elderly man, while his lower parts were like the hind quarters of a goat, whose horns he likewise bore on his forehead. His emblems were the shepherd's crook and pipe of seven reeds, his own invention. The name Pan is derived probably from the Gr. παειν, *to tend flocks*, which, as being the most general mode of life in primitive times, has led to the belief that this god was a symbol of Universal Nature; an idea to which Milton alludes in the beautiful lines, —

> ——— while Universal Pan,
> Knit with the Graces and the Hours in dance,
> Led on the eternal spring.

PANACE'A (Gr. παν, *all*, and ακεομαι, *I cure*), signifies a remedy which professes the power of curing all sorts of diseases. The word is said to be derived from Panacea, a daughter of Esculapius, the goddess of health, to whom, in conjunction with her better known sister, Hygeia, the power of healing all diseases was ascribed.

PA'NATHENÆ'A. (Gr. Παναθηναια; from παν, *all*, and Αθηναῖος, *Athenian.*) The great national festival of the inhabitants of Attica, celebrated in honour of Minerva. There were two solemnities of this name, the great and little. The former were celebrated once in every five years; the latter in every third year, or, as some think, every year. The exhibitions at these festivals were torch races, gymnastic, and musical, and poetical contests, with sacrifices and feasts; and, at the great

Panathenæa, the sacred stole (πέπλος), decorated by the hands of chosen virgins with embroidery representing the deeds of heroes and patriots, was hung like a sail on a machine in the form of a ship, and thus conveyed up to the Acropolis in a procession, and placed on the statue of Minerva.

PANCA'RTES, or PANCHARTÆ. In Diplomatics, royal charters, in which the enjoyment of all his possessions (enumerated in the instrument) is confirmed to a subject. The word, however, is used in other and looser significations.

PANCRA'TIUM. (Gr. παγκρατιον; from παν, *all*, and κρατειν, *to subdue*.) A kind of athletic contest practised by the Greeks, which combined wrestling and boxing together.

PA'NCREAS. (Gr. παν, and κρεας, *flesh*, from its fleshy consistence.) A glandular viscus of the abdomen, situated under and behind the stomach; its duct enters the duodenum, into which it conveys a fluid very like the saliva. Its use appears to dilute the bile, and render it more miscible with the food. It is commonly called the *sweetbread* in animals.

PANDÆMO'NIUM. (Gr. παν, and δαιμων, *a demon*.) The general appeliation bestowed by Milton on

—— the high capital
Of Satan and his peers. *Par. Lost*, i. 81.

PANDANA'CEÆ. (Pandanus, one of the genera.) A natural order of Arborescent Endogens inhabiting the Indian Archipelago, and most of the tropical islands of the old world. They have the aspect of gigantic pine-apples, bearing the flowers of a sparganium; and are remarkable among arborescent Monocotyledons for their constant tendency to branch, which is always effected in a dichotomous manner; and also for their leaves being arranged so distinctly in a spiral manner that they have acquired the common name of *screw pines*. The seeds of *Pandanus* are eatable.

PA'NDECTS, or DIGEST. (Gr. πανδεκτα; from παν, *every thing*, and δεχομαι, *I receive*.) The great compilation of the Roman law published by the Emperor Justinian. *See* DIGEST.

PANDO'RA. (Gr. παν, and δωρον, *a gift*.) Literally *the all-gifted*. In Grecian Mythology, the name given to the first mortal female, according to Hesiod, that ever lived. She was formed of clay by Vulcan, at the request of Jupiter, and was created for the purpose of punishing Prometheus (*see* PROMETHEUS) for his numerous impieties. All the gods vied in making her presents: thus, from Venus she received beauty, from the Graces the power of captivating; Mercury taught her eloquence, and Minerva wisdom; but Jupiter gave her a box filled with innumerable evils, which she was desired to give to the man who married her. She was then conducted to Prometheus, who, sensible of the deceit, would not accept of the present; but his brother Epimetheus, not gifted with the same prudence, fell a victim to Pandora's charms, accepted the box, from which on its being opened there issued all the ills and diseases which have since continued to afflict the human race. Hope alone remained at the bottom of the box, as the only consolation of the troubles of mankind.

PANDOU'RS. A kind of light infantry, formerly organized as separate corps in the Austrian service; raised from the Servian and Rascian inhabitants of the Turkish frontier, and originally under leaders of their own, styled Harumbachas. Since 1755, they have been included in the regular army.

PANDURIFORM. Literally, *fiddle-shaped;* applied by botanists to the leaves of some plants.

PANEGY'RIC. (Gr. λόγος πανηγυρικος, *a speech addressed to a general assembly*, and πανήγυρις, *panegyric*.) In Oratory, an eulogy or harangue, written or spoken, in praise of an individual or body of men. Among the ancients, orations were recited in praise of the departed on various occasions, before solemn assemblies: hence the name. Among the later Romans, the baser practice prevailed of reciting panegyrical orations on distinguished living persons in their presence. Among the moderns, panegyrical oratory has been chiefly confined to funeral discourses from the pulpit. In France, however, the eloges or orations, pronounced in some literary and scientific societies on the decease of a member, bear something of the character of classical panegyrics.

PA'NEL. In Law, said by Sir H. Spelman to mean "schedula," or "pagina," as a *panel* of parchment, &c. It commonly designates the roll containing the names of jurors whom the sheriff returns to pass on a trial. In Scottish law, the accused person in a criminal action from the time of his appearance is styled the "pannel."

PA'NIC (Lat. Pan), is usually applied to a sudden and groundless alarm. The word originated in the stratagem which Pan had recourse to, during the Indian expedition of Bacchus, on being surrounded by a numerous army; viz. ordering his men suddenly to raise a simultaneous shout, which, favoured by the echoes of a rocky valley, had the appearance of so augmenting their numbers that the enemy were inspired by terror, and instantly took to flight.

PA'NICLE. A form of inflorescence in which the primary axis develops secondary axes, which themselves produce tertiary; or, in other words, a raceme bearing branches of flowers in place of simple ones.

PA'NNEL, or PANEL. (Fr. panneau.) In Architecture, an area sunk from the general face of the surrounding work. In Joinery, it is a tympanum, or thin piece of wood, framed or received in a groove by two mounters or upright pieces, and two traverses or cross pieces.

PA'NOPLY. (Gr. παν, and ὅπλον, *armour*.) Literally all the armour that can be worn for defence; complete armour.

PANO'PTICON. (Gr. παν, and οπτομαι, *I see*.) A term coined by Jeremy Bentham to denote the plan of the prison which he designed and recommended for adoption in his *Theory of Punishments*. This building was distinguished by three leading properties, for an account of which the reader is referred to vol. xxii. of the *Edin. Review*, pp. 19, 20.; but its greatest peculiarity consisted in its form, and in the disposition of its cells, which were so constructed that the inspector could see each prisoner at all times without himself being seen; and hence the origin of the term.

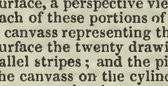
PANORA'MA. (Gr. παν, *all*, and ὁραω, *I see*.) A picture in which all the objects of nature that are visible from a single point are represented on the interior surface of a round or cylindrical wall, the point of view being in the axis of the cylinder. The rules according to which the different objects are represented in perspective are easily deduced from the consideration that the lines on the panorama are the intersections of the cylindrical surface of the picture with one or more conical surfaces having their summits at the point of view, and of which the bases are the lines of nature which the artist proposes to represent. In executing this kind of perspective the artist divides the horizon into a considerable number of parts, twenty, for example, and draws, in the ordinary way, on a plane surface, a perspective view of all the objects comprised in each of these portions of the horizon. He then paints on a canvass representing the development of the cylindrical surface the twenty drawings, in as many vertical and parallel stripes; and the picture is completed by stretching the canvass on the cylindrical wall of the rotunda which is to contain the panorama. When a painting of this kind is well executed, its truth is such as to produce a complete illusion. No other method of representing objects is so well calculated to give an exact idea of the general aspect and appearance of a country as seen all round from a given point.

The first panorama exhibited in London was painted by Barker in 1793; it represented the objects about Portsmouth and the Isle of Wight. A panorama of London was the first that was introduced into Germany, in 1800. Since that time they have become common in all the principal cities of Europe.

PANSTE'REORA'MA. (Gr. παν; στερεὸς, *solid*, and ὁράω, *I see*.) In Rilievo, a model of a town or country in cork, wood, pasteboard, or other substances.

PA'NSY. (Fr. pensée, *a thought*.) A term applied chiefly to the garden varieties of *Viola tricolor*, and others which are usually cultivated under the name of *heart's ease*. *See* VIOLA.

PA'NTAGRAPH. (Gr. παν, and γραφω, *I write*.) Frequently but improperly written *Pentagraph*. An instrufor copying, reducing, or enlarging plans. It consists of a jointed rhombus, A B C D, made of wood or brass, and having the two sides B A and B C extended to double their length. The side A D and branch A E are graduated from A, in such a manner that if O and T be corresponding divisions, A O is to B O in the same ratio as A T to B E or B F. Small sliding boxes for holding a pencil or tracing point are brought to the corresponding graduations, and fixed in their positions by screws, and a third is fixed at the point F. Now, since in every position of the instrument the two sides A D and B F are parallel, and the points O and T are so taken that OA : A T : : O B : B F, the three points O, T, and F must necessarily range in a straight line; consequently, if any one of these three points be taken as the centre of motion, and another of them be carried along the boundaries of any figure, the third will trace out a similar figure, reduced or enlarged according as it is nearer to or farther from the centre of motion than the point which is carried along the figure to be copied. Suppose the point O to be made the centre of motion, the tracer to be fixed at F, and the crayon or drawing point at T, the division of A D corresponding to O; then, while F is carried along



any figure, T will describe a similar figure reduced in the proportion of O T to O F, or of O A to O B. But if the tracer be fixed at T, and the drawing point at F, the copy will be enlarged in the proportion of O B to O A; or, if the fulcrum be placed at T, the tracer at O, and the crayon at F, the figure delineated will be enlarged in the proportion of O T to T F. If the points O and T be brought to coincide with E and D, and the fulcrum be placed at D; then, the distance E D and D F being equal, the original figure will be transferred into a copy of exactly the same dimensions. The pantagraph was invented by the Jesuit Christopher Scheiner in 1603, and is described by him in a tract entitled *Pantographice sive Ars Delineandi, &c.*, published at Rome in 1623. A more perfect instrument for accomplishing the same objects has recently been invented by Professor Wallace of Edinburgh, who has given it the name of *Eidograph:* for a description of which see the *Transactions of the Royal Society of Edinburgh*, vol. xiii.; or *Wallace's Geometrical Theorems and Analytical Formulæ*, 1839. Both instruments may be so modified as to produce a reversed representation of the figure to be copied; an application which is extremely useful for the purposes of copper-plate engraving and lithography.

PA'NTALOON. One of the chief characters in all pantomimic representations. He was originally dressed in a manner similar to that from which a well-known article of modern dress has derived its name. His name is said by antiquarians to be derived from the Italian words "Pianta-leone," as it were the "lion-planter," in allusion to the boastful language of the Venetians. (See *Lord Byron's Childe Harold*, canto iv.) The pantaloon of the original Italian pantomime was a Venetian burgher.

PANTE'CHNICON (Gr. παν, and τεχνη, *art*), signifies a place in which, as the term imports, every species of workmanship is collected and exposed for sale. The large building near Belgrave Square is an excellent specimen of this modern invention.

PA'NTHEISM. (Gr. Παν, and Θεος, *God.*) In Metaphysical Theology, the theory which identifies nature, or the τὸ πᾶν, the universe in its totality, with God. This doctrine differs from atheism in the greater distinctness with which it asserts the unity and essential vitality of nature; parts of which all animated beings are. The most ancient Greek philosophers were pantheists in this sense; Anaxagoras being the first who distinctly stated the coexistence with nature of a reasonable creator — "a mind, the principle of all things." In this sense, too, Spinoza may be called a pantheist. The pantheism of Schelling, and many modern German philosophers, is of a different stamp. According to these thinkers, God is conceived as the absolute and original Being, revealing himself variously in outward nature, and in human intelligence and freedom. It is not easy to see how pantheism in this sense differs from the Christian view of God, as expressed in the sublime language of St. Paul, "In whom we live, and move, and have our being." The world is, indeed, conceived to be animated by the presence and agency of the Deity; but his distinctness and independent subsistence are definitely laid down as the condition and ground of all phenomenal existence, and of reason itself. God may exist without the world, but the world is inconceivable without God. (See this article in *Ersch and Gruber's Encyclopædia.*) It must, however, be remarked, that many pseudo-philosophers of modern times assume the name of Pantheists as a convenient medium for the dissemination of *atheistical* opinions which they have not the courage boldly to avow.

PANTHEI'STIC. (Gr. Παν, and Θεος, *God.*) In Sculpture, a term applied to statues and figures which bear the symbols of several deities together, the meaning of which has been a subject of much dispute among antiquaries.

PANTHE'ON. (Gr. πάνθειον; from παν, *all*, and θεος, *a god.*) A temple dedicated to all the gods. Two magnificent structures of this kind existed in antiquity; one at Athens, the other at Rome. The latter, which still exists, though comparatively in ruins, is one of the most splendid remains of the ancients. The foundation of this building is generally ascribed to Agrippa, the son-in-law of Augustus. It now forms a Christian church, dedicated to the Virgin Mary and All Saints, and generally called the Rotunda. The form is circular, and its roof a hemispherical dome 144 feet diameter, its height being the same from the pavement to the top of the dome. It has a noble Corinthian portico, consisting of sixteen granite columns of the Corinthian order, of which eight stand in front. Pliny ranked this edifice as one of the wonders of the world. Since its erection it has been grievously spoiled of its ornaments. The term pantheon has been applied to places of public exhibition in which every variety of amusement is found. It is also used for a work containing a view of the mythology or all the gods of the ancients (as the term imports); as in *Tooke's Pantheon.*

PANTOCHRONO'METER. (Gr. παν, χρονος, *time*, and μετρον, *a measure.*) A term recently invented and applied to an instrument which is a combination of the compass, the sun-dial, and the universal time-dial, and performing the offices of all three.

PANTOLO'GIA. (Gr. παν, and λογος.) A work of universal instruction or science; equivalent to *dictionary* or *encyclopædia*, which see.

PA'NTOMIME. (Gr. παν, and μιμεω, *I imitate.*) A species of theatrical entertainment, in which, according to the derivation of the word, the whole action of the piece should be represented by gesticulation, without the use of words: also, a theatrical performer skilled in mimicry. The English pantomime is an amusement peculiar to our theatre. A class of actors in vogue at Rome, who performed pieces in dumb show, expressing every thing by their dancing and gestures, were also called pantomimes, and were in all probability the archetypes of this species of amusement among ourselves. (See the *Conversations-Lexicon;* and as to ancient pantomimes, *Mem. de l'Ac. des Inscr.* vol. xxiii.) *See* MIMES.

PA'PACY. The office of pope, or, historically, the succession of popes in the see of Rome. The origin of the term is oriental. The word papas was used in lower Greek with the signification of father, and is still applied by the Greek church to the priests of that communion. In the Western church, the title was not uncommonly given to bishops in general, and was not confined to the Roman pontiff for several centuries. In this article it will be our endeavour to trace, with the conciseness which our limits demand, the steps by which the bishops of Rome attained to the vast religious and political importance which they once possessed, and of which they still retain the shadow.

1. It is generally agreed that a certain degree of deference was paid to the church of Rome by the Christian societies dispersed throughout the empire in the primitive age. As St. Peter appears to have held a certain prominency among the apostles, so was his see looked up to, and its advice occasionally resorted to, by the other metropolitan churches, which, though its equal in rank, might allow to it some moral superiority. But, as the other apostles did not hesitate to rebuke St. Peter when his conduct appeared to their judgment to deserve it, nor to take the lead and initiative when he paused in the career which the Holy Spirit pointed out, so we find Irenæus of Lyons interfering to check the dogmatism of Victor of Rome, and Cyprian maintaining the validity of heretical baptism, in concert with the Asiatic church, and in opposition to the Roman.

2. It is in the fourth century that the first dawn of substantial power appears in the Roman see. Upon the recognition of Christianity by the civil government, the bishop of Rome is found in the enjoyment of precedence among the prelates of the empire. The patriarch of Constantinople is expressly exalted by Theodosius (A. D. 381) to the *second* rank. The canons of the council of Sardis, 347 (the genuineness, however, of which is suspected), allow bishops in certain cases an *appeal* to the Roman pontiff. Even the removal of the seat of government to Constantinople, although the very fact of its residence at Rome had undoubtedly contributed to the pre-eminence of its bishop in earlier times, seems to have favoured the pretensions which the popes began now openly to maintain. Rome was no longer under the immediate eye of the emperor. The patriarch of Constantinople, although he enjoyed the imperial favour up to a certain point, was not allowed to outstep it, and was subject to be deposed if he forgot for a moment the relative position in which he stood. The emperors of the West, on the other hand, took up their abode at Milan, or Ravenna; and when they had been overturned, and the barbarians began to found new dynasties upon the ruins of the Italian provinces, the popes were among their most useful instruments in civilizing and consolidating the fragments of their power.

Again, the nearer contact which thus took place between the Italian clergy and the children of the pagans of the north afforded the popes an opportunity of diffusing the idea of their own supremacy, at the same time that they extended the limits of Christianity; and while Antioch and Alexandria were trembling before the birth of Mahometanism, and Constantinople was losing one by one its fairest provinces and strongest partizans, the dominion of the Western primacy was acquiring daily a wider basis and a more devoted people.

3. With Gregory I., at the end of the sixth century, commenced one of the most important epochs in the papal history. The system of aggrandizement, of which he laid the foundations, consisted in the conversion of the heathen, upon the principle above mentioned, and the connection of the monastic orders with the Roman see, by releasing them from the immediate jurisdiction of their own diocesans.

4. The next important step in our history is the famous donation of Pepin, by which the Italian provinces which the French king had conquered from the Lombards were transferred by him, not to his own dominions, nor

to the Greek emperor, who had the ancient hereditary claim, but in temporal sovereignty to the pope. But even this political power, thus acquired, was not in itself pregnant with such important consequences as the principle which was sanctioned by the immediate occasion of the donation; for Pepin had taken counsel with Pope Zachary whether he should be justified in overturning the throne of the imbecile prince whose servant he was, and had been formally authorized so to do. However, the possessions which thus came into the hands of the Roman bishops, confirmed and enlarged by the addition of the territory of Rome itself by Charlemagne, at the close of the eighth century, have continued up to this day, with little extension or diminution, to form the temporal patrimony of St. Peter. It is to be observed, that the nature and extent of the power accorded to the popes by Charlemagne has given rise to much dispute; and the partizans of the Roman see have been charged with giving to it a false and exaggerated colouring. "The most probable account of the matter," says Mosheim, "seems to be this, that the Roman pontiff possessed the city of Rome and its territory by the same right that he held the exarchate of Ravenna, and the other lands which he received from Charlemagne; that is to say, that he possessed Rome as a feudal tenure, though charged with less marks of dependence than other fiefs generally are, on account of the lustre and dignity of the city which had so long been the capital of the empire." (*Cent. VIII.* pt. 2. cap. 2. note.)

5. The dissensions which took place among the successors of Charlemagne in the 9th century afforded a tempting opportunity for political encroachment on the part of the Roman bishops. In 879, Charles the Bald was proclaimed emperor by Pope John VIII., and his immediate successors received their nomination also from the same source. It was in the same century that the forgery of the decretal epistles gave a colour and authority to many temporal claims of the Roman see.

6. It was not, however, till the pontificate of Gregory VII. (1073—1086), that the principle of temporal aggrandizement which we have been tracing received a systematic development. The grand project which that prelate entertained was to reduce the whole territory of Christendom to a feudal subjection to the holy see. He assumed the right of appointment to all the crowns of Europe; and with such success that when his principal opponent, Henry IV. of Germany, had succeeded in dispossessing him of his pontifical chair, and placing therein the antipope, Clement III., the victorious monarch continued to recognize, in the creature whom he had thus installed in the papal prerogatives, the very same authority which Gregory had claimed over him, and received from his hands his own imperial crown. A main feature in this political scheme was the reduction of the whole body of the clergy into immediate dependants upon the papal throne. In order to effect this, the law of celibacy was strictly enforced; the elections of bishops by their diocesan clergy discouraged and almost abolished; and their investiture by their national sovereigns, in itself a monarchical usurpation, became the great subject of contention between the pope and the emperor; in which, though the former was finally unsuccessful, yet principles were advanced during its progress, and claims bequeathed to posterity, which smoothed the way for the more fortunate aggressions of later pontiffs, and exalted the power of the papacy to its greatest height under Innocent III. at the beginning of the 13th century.

7. The power of excommunication had long been exercised and wantonly abused before the time of Gregory; the interdict, by which a whole state was laid under a spiritual ban, was not adopted till about that period. This weapon was unsparingly wielded by Innocent III.; and the degradation to which John of England was subjected by him through these means is one of the strongest instances of the extent to which the papal power was advanced. But Innocent, although his clergy were better disciplined subjects, and his pretensions invested with the superior efficacy of prescription, had new and greater difficulties to contend with than his famous predecessors. At this time the tide of human opinion was already on the turn. Numerous reforming sects arose and threatened to undermine the fidelity of the lower classes; the princes were more conscious of the yoke which had been imposed upon them, and more anxious to avail themselves of an opportunity to cast it off: the clergy also, the main stay of the papal cause, were beginning to excite general murmurs by their corruption of manners. It is between Gregory and Innocent, therefore, that the period of the substantial greatness of the Roman see must be placed by the historian who contemplates both eras from a distance, and observes the seeds of decay which began to manifest themselves in the latter. The violence, however, and assumption of power, which had increased up to this time, continued to grow under the successors of Innocent, who appear not to have felt, even up to the Reformation itself, that the foundations of their authority were slipping rapidly from under them. But the same causes which we have enumerated as counteracting the apparent glory of Innocent's pontificate continued to work steadily against his successors; and at length when Luther arose to combine the force resulting from the three, the papacy, though relaxing nothing from its extravagant pretensions, found itself suddenly shorn of one third of its subjects entirely, and deprived of a great proportion of its authority over the rest. From that time to the present the power of the papacy has continued to retrograde, even in spiritual matters. It has been forced to concede a certain degree of independence to the clergy of France, and to enter into disadvantageous concordats with Napoleon and some of the German princes. It has even encouraged its writers in disclaiming the schemes of its earlier pontiffs, and allows them to assert the interference of the church between the prince and the subject to be tyrannical and unchristian. Its spiritual influence, however, although harassed on all sides by the free and discursive opinions of the day, continues still, from its combined pressure and elasticity, to be the most remarkable feature of modern history; its share in the recent political events of Europe has been very great, while the number of its subjects is probably at this moment much greater than at the times of Gregory or Innocent.

PAPA'VERA'CEÆ. (Papaver, one of the genera.) A natural order of narcotic plants, belonging to the Polypetalous division of the Exogenous class, and nearly related to *Ranunculaceæ*, with which it corresponds in habit and the structure of the seeds, but differs in having parietal placentæ and a calyx of only two pieces. The common poppy, the horned poppy, argemône, and some other genera, are well-known species, either cultivated for the sake of their flowers, or destroyed as showy but troublesome weeds. Opium is the inspissated juice of *Papaver somniferum*.

PA'PER. (Gr. *πάπυρος*; Fr. *papier*.) A thin and flexible substance of various colours, but most commonly white, used for writing and printing on, and for various other purposes. It is manufactured of vegetable matter, reduced to a pulp by means of water and grinding; and is made up into *sheets*, quires, and reams, each quire consisting of twenty-four sheets, and each ream of twenty quires.

For the chief purposes to which paper is applied in modern times the ancients had recourse to a variety of materials; stone, tablets of wood, plates of lead, skins, parchment, linen, layers of wax, tablets of ivory, and, above all, the papyrus. The ability to write created a necessity for some material on which to inscribe; and all these various materials were resorted to in succession, as the ineligibility of each induced a fresh endeavour to discover some more desirable substitute.

As our present object is to trace the progress of paper, rather than to enter into a minute account of those materials which were employed antecedent to its manufacture, it will not be necessary to dwell upon the other substances, which are as diversified as human ingenuity could devise; but pass on to the papyrus, the immediate precursor of paper, and the article from which it was first manufactured. Egypt has the honour of the invention; and Isidore even fixes the locality at Memphis: the date remains in some obscurity, although it has been warmly disputed. Varro, the Roman, ascribes it to the time of Alexander the Great, after the founding of Alexandria; but we find in Pliny the recital of a passage, extracted from the writings of Cassius Hemina, an ancient annalist, in which he speaks of some books found in the tomb of Numa when it was opened, 535 years after his decease, and asserts that these books were of *paper*, and had been interred with him. As Numa preceded Alexander 300 years, this circumstance, if admitted, would carry back the date of the invention anterior to that time. However, the antiquity of such a date is much doubted; but as Pliny gives an account of the manner of making the papyrus paper, and it seems to have been in high reputation in the time of Alexander the Great, it is probable that such improvements were made during his reign as to enhance the value and increase the manufacture.

It is true that papyrus continued in use long after the invention of paper; and this is the argument by which it is contended that the manufacture was of more modern date, although the only fair inference seems to be that it was only rare or expensive. It appears, however, that after this time papyrus paper was chiefly manufactured at Alexandria, and continued a source of profit to that city up to the fifth century, to the close of which it remained in general use throughout Europe; Italy retained it to the eleventh, and France even so late as the twelfth century.

We have thought it right thus briefly to narrate the differences of opinion which have prevailed respecting the origin of paper. Our own belief is, that the transition of the use of the papyrus in its natural state to that in its manufactured was so gradual, that it does not leave room to fix on any precise point at which to

say that the papyrus became paper. Probably the first step arose from the perception that the leaf was not strong enough for its purposes; and then how simply came the remedy of placing the leaves together, the waters of the Nile, amid which the plants grew, serving to cement them; afterwards came a pressure to flatten the transverse leaves; and this simple process seems to give the origin of paper. We believe that many an invention for which the learned have contended, has advanced by steps as simple and as gradual, leaving it impossible to decide at what point invention began, since it was only improvement that was taking place.

The next improvement in paper was its manufacture from cotton. It is supposed that the Chinese and Persians were acquainted with this material for its production, and that the Arabians learnt it from their conquest in Tartary. The ancient paper bears no marks of the wire through which the water is drained in modern paper-making; and it is therefore inferred that a different process was employed. Paper made from cotton was in use earlier with the Greeks than with the Romans. The manufacture of paper from cotton cannot be traced further back than to the tenth century; and the oldest manuscript document written on this cotton paper is dated 1050.

When or by whom linen paper was invented seems uncertain: some give the credit to Germany, some to Italy, some to Greece; but the Chinese appear to have the best pretensions. The Rev. Dr. Dibdin, in his *Typographical Antiquities*, says that "the art of paper-making with linen rags is supposed to have been discovered in the eleventh century, though Father Mabillon thinks it was in the twelfth. Montfaucon acknowledges that he has not been able to meet with a single leaf of paper with a date anterior to the death of St. Louis in 1270." Its introduction into England took place about the year 1342, in the reign of Edward III., although some have supposed it as early as 1320. France had it in 1314, and Italy in 1367. The Germans possess a specimen bearing the date of 1308, although it has been surmised that this single instance may have been a mixture of linen with cotton.

In the Preface to the *Kalendars of the Exchequer*, published by the Record Commission, it is stated that "some of the letters addressed to Hugh le Despencer, from Gascony (at various periods in the reign of Edward II.), are written on very stout and beautiful vellum; others on paper, of a sound and strong fabric, well sized, and such as may altogether be called a good article. And although, in the Tower, there are a few letters upon cotton paper, yet parchment or vellum was generally used; and these are amongst the earliest examples of any continued correspondence upon the more commodious material, which in England was very rarely employed. It is highly probable that, in the south of France, the supply was received from the Moorish merchants or manufacturers of Spain." "The original register of the privy seal of Edward the Black Prince from July, 20 Edw. III., to January, 21 Edw. III., forming one volume, is on paper."

It is a commonly received opinion that the first paper mill was erected in England during the reign of Elizabeth; though it has been asserted that the first mill was set up in Charles the First's reign, by a German of the name of John Spilman, or Spielman; that the king granted him a patent, and a salary of 200*l.* a year. Both these opinions are proved to be erroneous by an entry in the privy purse expenses of Henry VII., dated May 25th, 1498, published in the *Excerpta Historica*. "For a rewarde yeven at the paper mylne, 16*s.* 8*d.*," which establishes with certainty an anterior date of full fifty years. Dr. Dibdin gives this account of Spilman, on the authority of Dr. Harris; but the statement is invalidated by Mr. Nicholls, in his *Progresses of Queen Elizabeth*, who has reprinted in that work a poem of the date 1588, of which the following is the title: — *A Description and playne Discourse of Paper, and the whole Benefitts that Paper brings, with Rehearsall, and setting foorth in Verse a Paper-myll built near Darthford, by an high Germaine, called Master Spilman, Jeweller to the Queene's Majestie*, 1588. Perhaps no other manufacture ever remained so long nearly stationary; though within the last fifty years such great and rapid improvements have been made in it, as to equal, if not to surpass, any other branch of manufacturing industry.

The application of paper to the purposes of writing and printing, and the fact of its being indispensable to the prosecution of the latter, render its manufacture of the highest utility and importance. But, even in a commercial point of view, its value is very considerable. France, Holland, and Genoa had, for a lengthened period, a decided superiority in this department. The finest and best paper being made of linen rags, its quality may be supposed to depend, in a considerable degree, on the sort of linen usually worn in the country where it is manufactured; and this circumstance is said to account for the greater whiteness of the Dutch and Belgian papers as compared with those of the French and Italians, and still more of the Germans. The rags used in the manufacture of writing-paper in Great Britain are collected at home; but those used in the manufacture of the best printing-paper are imported principally from Italy, Hamburgh, and the Austrian states, by way of Trieste.

We believe, however, that it was owing rather to the want of skill than, as has sometimes been supposed, to the inferior quality of the linen of this country, that the manufacture of paper was not carried on with much success in England till a comparatively recent period. During the 17th century most part of our supply was imported from the Continent, especially from France. The manufacture is said to have been considerably improved by the French refugees who fled to this country in 1685. But it is distinctly stated in the *British Merchant* (vol. ii. p. 266.), that hardly any sort of paper, except brown, was made here previously to the Revolution. In 1690, however, the manufacture of white paper was attempted; and, within a few years, most branches were much improved. In 1721 it is supposed that there were about 300,000 reams of paper annually produced in Great Britain, which was equal to about two thirds of the whole consumption. In 1783 the value of the paper annually manufactured was estimated at 780,000*l.* At present, besides making a sufficient quantity of most sorts of paper for our own use, we annually export about 100,000*l.* worth of books. We still, however, continue to import certain descriptions of paper for engravings from France, and a small supply of paper-hangings. The duty on both amounts to about 2800*l.* a year.

In 1813, Dr. Colquhoun estimated the value of paper annually produced in Great Britain at 2,000,000*l.*; but Mr. Stevenson, an incomparably better authority upon such subjects, estimated it at only half this sum. From information obtained from those engaged in the trade, we incline to think that the total annual value of the paper manufacture in the United Kingdom, exclusive of the duty, may at present amount to about 1,200,000*l.* or 1,300,000*l.* There are about 700 paper-mills in England, and from 70 to 80 in Scotland. The number in Ireland is but inconsiderable. About 27,000 individuals are supposed to be directly engaged in the trade; and, besides the workmen employed in the mills, the paper manufacture creates a considerable demand for the labour of mill-wrights, machinists, smiths, carpenters, iron and brass-founders, wire-workers, woollen manufacturers, and others in the machinery and apparatus of the mills. Some parts of these are very powerful, and subject to severe strain; and other parts are complicated and delicate, and require continual renovation. Owing to this, the manufacture is of much greater importance, as a source of employment, than might at first be supposed, or than it would seem to be considered by government, who have loaded it with an excise duty amounting to more than three times as much as the total wages of the work-people employed!

We pass on from this brief account of the history and statistics of paper to the mechanical process of its production; only remarking, that many articles have been resorted to in its manufacture, — the tendrils of the vine, the stalks of the nettle, the thistle, and mallow *; the bark of the willow, the hawthorn, the beech, the aspin, and the lime. Some patents have been obtained for making it of straw; and the bine of the hop, it is presumed, might furnish material for the supply of paper to all England; but, leaving these inferior substitutes, we shall confine ourselves to the description of paper made from linen rags, that being the staple of the manufacture.

The rags in the London market are sold to the manufacturers according to their respective quality, under the terms fine, 2d, 3d English rags; and SPFF, SPF, FF, &c. foreign rags: fine being wholly linen, and of the best quality, is used for the finest writing paper, and so in their gradation down to the commonest, which is coarse, often canvass, and can only be made into an inferior printing paper when it has been thoroughly bleached. In these inferior papers some cotton is mixed. There are also the strong coarse bags in which the rags are packed, and the coloured rags, only fit for the most common papers; though out of these the blue are usually sorted for the purpose of making blue paper. It is necessary that these rags should be dusted; and, to accomplish this, they are either placed in a cylinder formed of wire net, turning on pivots at each end, and enclosed in a box which receives the dust as it falls through the net-work, or else their

* The works of the Marquis de Villette, published in London, 1786, in 24mo., are printed on paper made of marshmallow; and at the end are specimens, in single leaves, of paper made of the nettle, hops, moss, reed, three of three species of conferva, couch grass, spindle trees, wayfaring tree, elm, lime tree, yellow willow, sallow willow, poplar, oak, two of burdock, coltsfoot, and thistle.

The Chinese make their paper in large sheets of the raw vegetable material; it has all the appearance of the pulp having been laid on a smooth flat surface with a brush, similar to painting, having one side smooth, and the other with the marks of the brush on it. It is unequalled in its quality of receiving a fine and delicate impression of engravings, either from copper or wood.

sorting takes place over a table frame covered with wire net, through which the dust falls into a box beneath as the workwoman proceeds in her labours. The first of these modes, however, is a great preservation of the health of those employed in the work. The rags are then cut into pieces not exceeding three or four inches square, the parts that have seams being thrown into a separate heap, or the sewing thread might make filaments in the paper. In this process the rags are scrupulously sorted according to their texture and degree of strength, not according to their colour; for, were they not carefully arranged by this rule, the fine in texture would be reduced to a pulp long before the coarse, and be lost in the preparation; or, if preserved, when reduced to pulp, would not be found of the same consistency as the coarser sorts, and the paper when manufactured would necessarily be clouded and inferior. It is for these reasons that this part of the process is important. When carefully sorted, and the different degrees of texture having, by a longer or shorter process, been reduced to a pulp of similar consistency, they may then be mixed together; but this cannot be previously done. While in this state the rags often appear so dirty and discoloured as to preclude all hope, to an inexperienced eye, that they can ever assume the purity of that beautiful fabric so valuable to the artist and the scribe. This purification used formerly to be effected by water running through a receptacle filled with the rags, which in its passage eventually carried off their soil; but the present more expeditious process is that of boiling them, mixed up with lime, in a species of chest, so perforated as to allow the admission of steam; and by this means they are partially bleached. It is but due to the superior cleanliness of our own country to state, that the rags collected in England require little bleaching; but, as these form a small proportion of the quantity used in our extensive manufactories, bleaching takes an important place in the process. The superfluous moisture is squeezed from the rags, and they are placed in a sort of chamber or receiver, which is air-tight, and pipes are conducted into it from a retort, which convey chlorine, formed, by the application of heat, from manganese, common salt, and sulphuric acid. This part requires much care; for if carried beyond its due point, it proves most injurious to the durability of the fabric. The rags when taken from this chamber are strongly imbued with a most nauseous smell, and require profuse and frequent washings. After this process they are put into the beating engines, and pass through a sort of trituration, which reduces them to a coarse and imperfect pulp, which is called half stuff or first stuff, and this is again levigated until it assumes the appearance of cream.

The state and quality of this pulp is of the utmost importance to the final perfection of the paper. If, in the levigation, the fibre should have been so entirely destroyed as to reduce it to a jelly, the paper will inevitably prove liable to break, moulder away, and be rotten; and this must result whatever the previous excellence of the material. A fibre is absolutely necessary to the production of a serviceable paper. Mr. Murray, in a little work on the subject full of practical science, recommends that a small proportion of unbleached flax should be added to the half stuff, — an expedient that would doubtless much increase the strength and durability of our manufacture. But, unfortunately, so far from means being taken to improve its consistency, others are resorted to, for the sake of an increased profit, which deteriorate almost to destruction: we mean the introduction of plaster of Paris, or other earthy substances, into the pulp; and this can never be done without ensuring brittleness and want of cohesion as the result. While the pulp is in this state, the size, made from sheep-skins and other animal substances, together with a solution of alum, is introduced; excepting only in the manufacture of writing paper, and then the sheets are most generally sized after their formation.

Having described the preparation of the material, we shall pass on to its formation into paper.

The fine pulp, or stuff, as it is technically called, is transferred into a chest or large tub with a revolving agitator; from thence into a vat, usually about 5 feet in diameter, and 2½ feet in depth, and sustained at a proper temperature by means of a fire; and it is generally arranged for this vat to be placed against a wall of the room, that the fuel to the fire may be supplied at an aperture externally, to prevent any injury from smoke. During the whole of the subsequent process it is requisite that the pulp in the vat should be stirred up at short intervals, to keep it of an equal consistency. There are three workmen employed in this stage of the operation, called the *dipper*, the *coucher*, and the *lifter*. The dipper is provided with a mould, formed of well-seasoned mahogany, across which parallel wires are stretched close together, a few other stronger ones being also placed at right angles with them, and at some distance from each other. The lines formed in the paper by these wires are called water-marks; but, in the modern improvement of wove paper, these are avoided by using wire cloth woven in a loom, which, being tightly stretched over the frame, produces no water-mark. This mould is provided with another frame, called a *deckle*, which fits it exactly, and forms a boundary line to the sheet of paper, which would otherwise have a rough and jagged edge. This contrivance, by supplying an edge to the mould, gives it the character of a sieve, which enables the dipper, after he has dipped the mould into the vat, and taken in a sufficient quantity of the pulp, and given it a gentle motion to equalize its thickness, to drain the water away; he then removes the deckle, replaces it on another mould, and proceeds as before; whilst the second workman, the coucher, removes the sheet of paper thus made on to a felt, being a piece of woollen cloth, and then returns the mould to the dipper, who, in the meantime, has been operating with another mould, and forming another sheet: they thus exchange the moulds, the one dipping, and the other couching, until they have completed six quires of paper, which is called a *post*. When this quantity is completed, the heap is conveyed to the vat press, and subjected to heavy pressure. These six quires remain in the vat press until the dipper and the coucher have perfected another post, when they are removed to give place to it; and then the office of the third workman, the lifter, commences. He separates the sheets of paper from the felts, and forms them into a pile, which is again subjected to a second press, which detaches from them a great quantity of moisture. Here it remains until the workmen are prepared to replace it with a similar quantity, when it is taken to the drying rooms, and hung up on lines to dry. These lines are carefully covered with wax, both to prevent adhesion and contraction; and the opening of the windows should be strictly attended to, that the drying may not proceed too rapidly. This being accomplished, it is taken down, shaken, to make the dust fall out, and to separate the sheets from each other, and laid up in heaps, ready to be sized. The size is prepared of a due consistence, twice filtered, and a portion of alum added. The workman dips a handful of the sheets, holding them open at the edges, that they may more equally imbibe the moisture, and after this process they are again subjected to the press. They are afterwards dried, sorted, brought under repeated and excessive pressure, and, finally, made up into quires and reams.

But as the process of paper-making must necessarily be comparatively slow when practised by hand, machinery has been resorted to, which has nearly supplanted the old method. We believe France has the honour of the invention, although it has been greatly improved in England by Messrs. Donkin and Co. That in most general use here is after Fourdrinier, who invented the endless web of wire. One of these machines can produce 25 superficial feet of paper per minute; and it is this which enables us to enter into competition with the foreign market, which we could not otherwise do, on account of the difference in the value of manual labour. In the old method, it took three months after receiving the rags into the mill to complete the paper: by the machine, they can receive the rags on one day, and deliver the paper made from them on the next.

The stuff, having been prepared and bleached in an expeditious manner by machinery, is emptied into the chest or tub, as before, and from thence is delivered gradually into the vat, where it is kept in continued motion by means of revolving fans, called *hogs*. Nearly at the top of the vat there is a gate, which can be raised or lowered at pleasure, by means of which the flow of stuff is regulated on to the lip or trough, from which it falls upon the endless web of fine wire, which is kept continually moving in a horizontal direction over a series of revolving rollers, and is placed immediately under the hanging lip of the trough, so that the pulp may have the shortest distance possible to fall. These revolving rollers prevent the wire web from falling in or bagging, and keep it level; and as it is preserved at a due tension from side to side, it has all the appearance of a table. A leather strap, or ledge of wood, on each side, forms the boundary line of the paper, answering the purpose of the deckle in the hand-making process; these are moveable according to the intended width of the paper. The long cascade or continuous stream of pulp, regulated with reference to the proposed thickness of the paper to be made, thus gently descends on this moving wire plane, which is perpetually travelling onward and onward; and, for its more perfect equalization, a second movement is resorted to, by means of a sort of crank, which gives the web a jerking motion at short intervals, and diffuses the liquid pulp unvaryingly over the surface. At the end nearest to the trough the pulp is, of course, perfectly fluid; but, as the web travels on, the moisture partially sinks through the fine apertures of the webbing, and the material coagulates. There has been a fashion prevalent of late years of having paper barred or ribbed: this appearance is given at this juncture. While yet moist, just before passing from the wire webbing, it is subjected to the pressure of a wire roller, which gives the indentations of the stripes or lines;

this cylinder is called a *dandy:* from this it travels to a web of cloth or felt, during which advance it is subjected to heavy pressures, from passing between rollers covered with felt, and called the *pressing rollers*. This process answers to the wet press in the hand-made paper; and formerly this was the termination of the labours of the machines, the remaining work of drying, &c. being accomplished by hand. But an incalculable improvement took place in the addition of the drying rollers. These are three cylinders of polished metal, which effect in a few moments the perfect drying of the paper: while yet moist it passes over the first moderately warm; again over the second, of larger diameter, of greater warmth; and again over the third with an augmented heat. The paper is now perfectly dry, and any casual inequalities are removed from its surface. The final action of this wonderful machine is to wind the paper round a last roller or reel, which when full is exchanged for another, and so on successively.

Here the work of the machine is finished; and the paper, being in long webs of many yards, requires to be cut into sheets. After different methods had been tried, a supplementary machine has been invented, which receives the web from off the reel on to a drum, cuts it into sheets of proper lengths with a circular knife, continually revolving, while the divided web proceeds; and these sheets are received and placed in regular heaps by children.

Mr. Dickinson has recently made great improvements in the machine, which has consequently been followed by a corresponding improvement in the paper manufactured by the house of Messrs. John Dickinson & Co., which has long been celebrated for producing paper of a superior quality.

The manufacture of the paper being thus completed, the sheets are separately examined, and every knot or blemish carefully removed, the torn or damaged ones being laid apart. In this state they are subjected to the action of a powerful press, in the full and open size of the sheet: they are afterwards cut round the edge, and then counted into quires of twenty-four sheets, which are folded in the middle, and put into reams, each ream containing twenty quires, of which the two on the outside are made up of twenty sheets each from the damaged sheets that were thrown out. In this state they are again pressed, and finally tied up in wrappers. These wrappers are stamped by the exciseman; and, by the act 6 & 7 Will. 4. c. 52., the paper is charged with an excise duty of three halfpence a pound.

When the duty on paper was charged according to the size, the makers were obliged to be particular in the dimensions. The following table shows the exact size of the different writing, drawing, and printing papers, as enforced by the excise under the powers vested in them by act of parliament.

	First Table. Writing.	Second Table. Drawing.	Third Table. Printing.
	Inches.	Inches.	Inches.
Double Atlas -	- -	55 by 31½	
Grand Eagle, or Double Elephant - -	- -	40 26¾	
Double Demy -	- -	- -	38½ by 26
Columbier -	- -	34½ 23½	
Atlas - -	- -	34 26¼	
Atlas, small -	- -	31 25	
Imperial - -	30½ by 22	30¼ 22	
Double Crown -	- -	- -	30 20
Elephant - -	- -	28 23	
Super Royal -	27½ 19¼	27½ 19¼	
Long Royal -	- -	27½ 18	
Royal - -	24 19¼	24 19¼	26 20
Ditto - -	- -	- -	24¼ 19½
Double Pott -	- -	- -	25½ 17
Large Fan -	- -	23½ 20½	
Small Fan -	- -	22¼ 13¼	
Medium - -	22½ 17½		23 18
Extra large Post - -	21 16½		
Thick and thin Post - -	19½ 15¼		
Small Post -	16½ 13½		
Demy, single -	- -	- -	22 17½
Ditto -	- -	- -	21½ 19¼
Demy - -	20 15½	22 17	
Short Demy -	- -	20¼ 14	
Copy, or Bastard - -	- -	20¼ 16	
Crown - -	- -	20 15	
Single Crown -	- -	- -	20 15
Foolscap - -	16¾ 13½	16¾ 13½	
Littriss Foolscap - -	- -	17½ 13½	
Pott - -	15½ 12½	15 12½	

It will be seen, by the preceding table, that the largest sheet of hand-made paper is 4 feet 7 inches in length by 2 feet 7 inches and a half in breadth; while machine-made paper is of the width of 5 feet, and appears to be unlimited as to its length.

PAPER HANGINGS. This important and elegant substitute for the ancient "hangings" of tapestry or cloth came into use about 200 years ago: the manufacture has undergone a gradual succession of improvements, and has now reached a high state of beauty and perfection. The patterns on these papers are sometimes produced by stencil plates, but more commonly by blocks, each colour being laid on by a separate block cut in wood or metal upon a plain or tinted ground. The patterns are sometimes printed in varnish or size, and gilt or copper leaf applied; or bisulphurate of tin (*aurum musinum*) is dusted over so as to adhere to the pattern; and in what are called *flock papers*, dyed wools minced into powder are similarly applied. Powdered steatite, or French chalk, is used to produce the peculiar gloss known under the name of *satin*. Striped papers are sometimes made by passing the paper rapidly under a trough, which has parallel slits in its bottom through which the colour is delivered; and a number of other very ingenious and beautiful contrivances have lately been applied in this important branch of art. The invention of the paper machine, by which any length of paper may be obtained, effected a great change in paper hangings, which could formerly only be printed upon separate sheets, and were much more inconvenient to print as well as to apply to the walls. A plausible suggestion upon the subject of "intellectual paper hangings" will be found in No. 504. of the *Penny Magazine*. The reduction of the duty on paper, and the repeal of that on paper hangings, not only create a greater demand for, but are likely to lead to further improvements in, this manufacture.

PAPER MONEY. *See* Banks.

PAPER SAILOR, or PAPER NAUTILUS. *See* Argonaut.

PAPIER-MACHÉ. A name given to articles manufactured of the pulp of paper, or of old paper ground up into a pulp, bleached, if necessary, and moulded into various forms. This article has lately been used upon an extensive scale for the manufacture of mouldings, rosettes, and other architectural ornaments; pilasters, capitals, and even figures as large as life, have also been made of it. It is lighter, more durable, and less brittle and liable to damage than plaster, and admits of being coloured, gilt, or otherwise ornamented. Another article sometimes goes under the same name which is more like pasteboard, consisting of sheets of paper pasted or glued and powerfully pressed together, so as to acquire when dry the hardness of board, and yet to admit while moist of curvature and flexure: tea-trays, waiters, snuffboxes, and similar articles are thus prepared, and afterwards carefully covered by japan or other varnishes, and often beautifully ornamented by figures or landscapes and other devices, &c., occasionally inlaid with mother of pearl. A mixture of sulphate of iron, quicklime, and glue, or white of egg, with the pulp for papier-maché, renders it to a greater extent water-proof; and the further addition of borax and phosphate of soda contributes to make it almost fire-proof. The chief papier-maché manufactory in England is that of Bielefeld, in Wellington Street, Strand, who has recently published a concise history of the manufacture, embellished with numerous illustrations.

PAPILIONACEÆ. *See* Leguminaceæ.

PAPILIONA'CEOUS. A name given to the corolla of leguminous plants, from its fancied resemblance to the figure of a butterfly: it is that of the garden pea and bean, and consists of a large upper petal or vexillum, two lateral petals called alæ, and two intermediate petals forming a carina.

PAPILIO'NIDÆ. (Lat. papilio, *a butterfly*.) The name of a family of Lepidopterous insects, of which the genus *Papilio* is the type. *See* Diurnals.

PA'PIST. (Lat. papa, *the pope*.) A word in common use to designate a member of the Roman Catholic church. It has a shade of meaning somewhat different from *Romanist*, being employed generally with a certain degree of prejudice and obloquy attached to it.

PA'PPUS. A name given to the calyx of Compositæ, which exists in the rudimentary condition of a cap or membranous coronet, or of slender hairs, or in some other similar condition.

PAPY'RI. The name given to the written scrolls, made of the *papyrus*, which have been found in various places, but more especially in Egypt and Herculaneum. The process of making papyri was as follows: — The interior of the stalks of the plant, after the rind had been removed, was cut into thin slices in the direction of their length; these being laid on a flat board in succession, similar slices were placed over them at right angles; and their surfaces being cemented together by a sort of glue, and subjected to a proper degree of pressure, and well dried, the papyrus was completed. The length of the slices depended of course on the breadth of the intended sheet, as that of the sheet on the number of slices placed in succession beside each other; so that though the breadth was limited, the papyrus might be extended to an indefinite length. Many of the papyri which have been preserved vary greatly in their texture and appearance: they are generally fragile and difficult to unrol until ren-

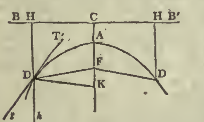
dered pliable by gradual exposure to steam or the damp of an English climate; and some are so brittle that they appear to have been dried by artificial means. (*Sir G. Wilkinson's Manners and Customs of the Ancient Egyptians*, vol. iii. p. 147–8.) Much interest was excited by the discovery of the papyri rolls at Herculaneum, and great expectations were entertained by archæologists that many of the valuable remains of antiquity would be restored to the world; but "after all the trouble that has been taken, and all the ingenuity that has been displayed in unrolling and deciphering many of them, little or nothing has been found worthy of the pains. They consist chiefly of Greek sophists and rhetoricians; works on music, medicine, and the arts; and some on natural and moral philosophy, &c. All the deciphered papyri are contained in the work *Herculaniensium Voluminum quæ supersunt*, published at Naples, 1827.

PAPY'RUS. In Botany, a Cyperaceous plant found in the districts of many tropical countries, but especially in the valley of the Nile, and whose soft cellular flower-stem afforded the most ancient material from which paper was made. Among the ancients the term *papyrus* formed the general appellation for all the different plants of the genus *Cyperus*, which was extensively used for making mats, baskets, boats, and many other purposes; the species confined to the manufacture of paper being usually designated *Cyperus papyrus*, or *Byblos*. The latter was particularly cultivated in the Sebennytic nome; though other parts of the Delta also produced it, and probably even some districts in Upper Egypt. The paper made from it differed in quality, being dependent upon the growth of the plant and the part of the stalk whence it was taken. The process of the manufacture is minutely described by Pliny in his *Hist. Nat.* xiii. 11, 12. The period at which paper began to be manufactured from the papyrus is involved in great obscurity; but there can be little doubt that Pliny was greatly in error when he assigned it a date posterior to the reign of Alexander the Great; for we meet with papyri (see above) of the most remote Pharaonic periods, the same mode of writing on which is shown from the sculptures to have been common in the age of Suphis or Cheops, the builder of the great pyramid, more than 2000 years before the Christian era. The manufacture of paper from the papyrus continued in general use down to the end of the 7th century, when it was superseded by parchment (which see).

PAR OF EXCHANGE. *See* EXCHANGE.

PA'RABLE. (Gr. παραβολη; from παραβαλλω, *I compare.*) In Rhetoric, in the original sense, a comparison; but the word has become, in modern language, appropriate in a particular meaning. The parables of the New Testament are illustrations, in the form of short tales, after the oriental manner, in each of which not only a moral or religious truth is conveyed, but the objects contained in the hidden sense are distinctly represented by parallel objects or types in the external narrative.

PARA'BOLA. In Geometry, one of the conic sections; formed by the intersection of the cone with a plane parallel to one of its sides. Considered as a plane curve, the parabola may be defined as follows:— A point F, and a straight line B B′, being given by position in a plane, let another point D be supposed to move in such a manner that its distance D F from the given point is always equal to its distance D H from the given straight line: the point D will trace out the parabola.



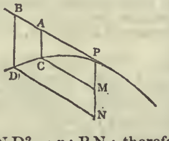
The given line B B′ is called the *directrix* of the parabola; the given point F is the *focus;* the straight line F C, drawn through F perpendicular to the directrix, is the *axis;* any straight line parallel to C F is a *diameter;* the point in which the diameter meets the curve is the *vertex* of the diameter; and a straight line, quadruple the distance between the vertex of any diameter and the directrix, is called the *latus rectum* or *parameter* of that diameter.

From the preceding definition of the curve its algebraic equation is easily found. Let A be the origin of the rectangular co-ordinates, $AK = x$, $KD = y$, and $AF = AC = a$: we have DK^2 or $y^2 = DF^2 - FK^2$; but $DF = DH = CK = x + a$, and $FK = AK - AF = x - a$; therefore $y^2 = (x+a)^2 - (x-a)^2$, whence $y^2 = 4ax$; or, if we assume $p = 4a$ (= the parameter of the axis), the equation becomes $y^2 = px$; that is, the square of the ordinate is equal to the rectangle under the absciss and the parameter. This property holds true of every other diameter as well as of the axis, the ordinate being taken parallel to the tangent at the vertex of the diameter. It was on account of this property that the curve received its name.

Let $FD = r$, and the angle $AFD = \phi$; then $FK = -r\cos.\phi$, and consequently $CK = 2a - r\cos.\phi$. But by the definition of the curve, $CK = FD = r$; therefore $r = 2a - r\cos.\phi$, whence $r = \dfrac{2a}{1+\cos.\phi}$. This is the polar equation of the parabola.

Let T *t* be a tangent to the parabola through D; it is a property of the curve that the angle H D T, and consequently the vertical angle *h* D *t*, is equal to F D T. A ray of light, therefore, falling on the curve in the direction *h* D, and being reflected by it, would pass through the point F; and as this takes place with regard to every ray parallel to the axis, it follows that the concave surface formed by the revolution of a parabola about its axis is that by which all the parallel rays of light are collected into a single point. Hence the point F is called the *focus*, or burning point.

Another remarkable property of the parabola is the following:— Let P A be a tangent to the curve at P, and from A and B, points in the tangent, let A C and B D be drawn parallel to the diameter P M N; then $AC : BD :: PA^2 : PB^2$.



For, making C M and D N parallel to P B, and assuming p = the parameter of the diameter P N, we have, from a property already mentioned, $MC^2 = p \cdot PM$, and $ND^2 = p \cdot PN$; therefore $MC^2 : ND^2 :: PM : PN$, or $PA^2 : PB^2 :: AC : BD$. Hence the parabola is the curve described by a projectile in a vacuum; for a body projected from P in the direction P A, and not resisted, would pass over spaces in that direction proportional to the times; and, in consequence of the accelerating force of gravity, it falls through spaces A C and B D in the perpendicular direction proportional to the squares of the times, or proportional to the squares of P A and P B. *See* GUNNERY, PROJECTILE.

The parabola is remarkable, as being the first curve of which the indefinite quadrature was found. Let P N be a diameter, and P B a tangent at its vertex, and B D and D N respectively parallel to P N and P B; it was demonstrated by Archimedes that the area contained by P N, N D, and the parabolic arc P C D, is equal to two thirds of the parallelogram P B D N.

The curve which has now been described is called the *conical* or *Apollonian* parabola; but the term parabola is also applied to all algebraic curves of a higher order determined by an equation of the form $y^{m+n} = a^m x^n$. The curve whose equation is $y^3 = a^2 x$ is called the cubical parabola; and that which has for its equation $y^3 = ax^2$, the semicubical parabola. This latter curve is celebrated in the history of the algebraic analysis as being the first curve that was rectified, or found equal in length to an assignable straight line; and the honour of the discovery belongs to an Englishman, William Neil, who died in 1670 at the early age of thirty-three. The same discovery was made nearly at the same time by Van Heuraet in Holland: till then it had been supposed by geometers impossible to assign a straight line equal to the arc of any algebraic curve (the rectification of the cycloid had been found by Sir Christopher Wren); but the discovery of the method of fluxions soon showed that there are innumerable classes of curves susceptible of indefinite rectification. In fact, all parabolas of this form $y^{2n+1} = ax^{2n}$, where n is any number whatever, may be rectified. (Montucla, *Histoire des Mathematiques*, tom. ii. p. 151.) *See* CONIC SECTIONS.

PARABO'LIC CONOID. The solid generated by the rotation of a parabola about its axis. It is equal in content to $\frac{1}{2}$ the circumscribed cylinder, and to $\frac{3}{2}$ of the cone having the same base and altitude.

PARABO'LIC CURVE. A curve of which the equation is of the form $y = a + bx + cx^2 + dx^3 +$ &c. Curves of this kind are frequently employed for the purpose of representing a number of observations, or for approximating to the areas of other curves; for it is always possible to cause a parabolic curve to pass through any number of points in a given curve, by making as many of the coefficients, *a*, *b*, *c*, &c., indeterminate as there are points given; and the curve thus described will differ less from the given curve according as the number of points is greater. But the area of the parabolic curve can always be determined; therefore that of the other curve may be found to any required degree of approximation.

PARABO'LIC SPINDLE. The solid conceived to be formed by the rotation of a parabola about its base, or double ordinate.

PARABO'LOID, is sometimes used to denote the parabolas of the higher orders; and sometimes the solid formed by the rotation of a parabola about its axis, or the parabolic conoid.

PARACE'LSISTS. Followers of the school of Paracelsus in medicine, physics, and mystical science. The founder of this school may perhaps be called with justice the most distinguished quack who ever made a figure in the world. He practised medicine "with the boldness of a wandering empiric," and established a

successful opposition to the traditionary doctrines of the so-called schools of Hippocrates and Aristotle. He mingled his medical and chemical knowledge with the speculations of the Cabbala, and with a theosophy of his own. He died in 1541. His followers continued to influence the schools of Germany for more than a century. (See *Hallam's Introduction to the Literature of the Middle Ages*, i. 541. 639. ii. 70. &c.; and *Mosheim*, vol. iv.)

PARACENTE'SIS. (Gr. παρακεντεω, *I perforate*.) The operation of *tapping* any of the cavities of the body for the purpose of withdrawing a contained fluid.

PARACE'NTRIC. (Gr. παρα, and κεντρον, *centre*.) In the higher Geometry, the name given to a curve line having this property, that a heavy body descending along it by the force of gravity will approach to, or recede from a *centre* or fixed point, by equal distances in equal times.

PARACENTRIC MOTION, in Astronomy, denotes the rate at which a planet approaches nearer to, or recedes farther from the sun or centre of attraction, in a given interval.

PARACE'PHALOPHO'RES. (Gr. παρα, *beside*, κεφαλη, *head*, and φερω, *I carry*.) A name given by M. De Blainville to a class of Mollusks, comprehending those in which the head is but little distinct from the body, but always provided with some of the organs of sense.

PARACHU'TE. (Fr. parer, *to ward off*, and chute, *fall; a guard against falling*.) An apparatus resembling the common umbrella, but of far greater extent, intended to enable an aëronaut, in case of alarm, to drop from his balloon to the ground without sustaining injury. This is effected by means of the resistance of the atmosphere. When the parachute is detached from the balloon, and abandoned with its load in the air, it must proceed at first, from the continued action of gravity, with an accelerated motion, until the increased velocity produces a resistance equal to the force of attraction, or the weight of the apparatus with its load. After this equilibrium has been attained, the parachute will descend with a nearly uniform velocity. According to theory, this terminal velocity, supposing the surface of the parachute to be flat, is equal to that which a heavy body would acquire in falling through the altitude of a column of air incumbent on that surface, and having the same weight as the whole apparatus. A circular parachute having a diameter of 30 feet, and weighing with its load 225 pounds, would acquire a terminal velocity of about 13 feet per second; and a person descending with it at this rate would receive the same shock on reaching the ground as if he dropped freely from a height of $2\frac{3}{8}$ feet. (For the method of solving this problem, see *Hutton's Mathematical Tracts*, vol. iii. p. 316.) The actual resistance of the air is, however, greater than is given by theory, and is besides augmented by the concavity of the parachute, which occasions an accumulation of the fluid; but, on account of the action of the wind, the axis of the parachute will probably become inclined to the vertical, in which case the resistance will suffer a diminution.

One of the most remarkable instances of descent from a great height with a parachute is that of Garnerin, a Frenchman, who ascended in a balloon from an enclosure, near North Audley Street, in London, on the 2d of September, 1802. After hovering seven or eight minutes in the atmosphere, he cut the cord by which his parachute was attached to the balloon. It instantly expanded, and for some seconds descended with an accelerating velocity, till it became tossed extremely, and took such wide oscillations that the basket or car was at times thrown almost into a horizontal position. The intrepid aëronaut narrowly escaped destruction by being precipitated on the houses in St. Pancras, and at last fortunately came to the ground in a neighbouring field. He seemed to be much agitated, and trembled exceedingly at the moment he was released from the car. (*Ency. Brit.*, "Aeronautics.")

A recent experiment of this kind, made by Mr. Cocking, was attended with fatal consequences. Having conceived a notion that the vibrations might be avoided by giving the machine a different form, this projector constructed one in the form of an inverted umbrella, that is, having the concave side uppermost, and bound to a strong wooden hoop to prevent its collapse in the descent. The diameter of the hoop was 34 feet; and there was also a hole of 6 feet in diameter in the middle of the parachute, which, it was supposed, would also contribute to give greater steadiness. Having attached himself to this machine, he ascended from Vauxhall Gardens on the 24th of July, 1837. On being cut away from the balloon the parachute descended rapidly, and with violent oscillations: the hoop broke, and the unfortunate projector fell, dreadfully mangled, at Lee, near Blackheath. The persons in the car of the balloon were also placed in great danger, having narrowly escaped suffocation from the quantity of gas expelled in consequence of the great velocity with which the balloon darted upwards immediately on being liberated from the parachute. They suffered extreme pain, and for a time were deprived of sight; but fortunately they had carried up with them a large bag filled with atmospheric air, by means of which they were enabled to breathe. Without this, they would probably have perished.

PA'RACLETE. (Gr. παρακλητος, *advocate*.) A name attached to the Holy Spirit, as an advocate, intercessor, or comforter of mankind; such as he is represented, John, xiv. 16. 26.; Rom. viii. 26. It was not an uncommon opinion of the early heretics, that the Paraclete, whose mission was promised by Christ, was to appear corporeally upon the earth, and complete the dispensation announced by our Lord and the apostles; and they drew a distinction between the person of the Comforter and the effusion of his grace upon the disciples on the day of Pentecost. Accordingly, several of them, Simon Magus, Manes, and others, gave themselves out as this expected Paraclete; and Tertullian himself was at one period infatuated by the claims advanced by Montanus to this personification.

PARACRO'STIC. A poetical composition in which the first verse contains, in order, all the letters which commence the remaining verses of the poem or division. According to Cicero (*De Divinatione*, ii. 54.), the original Sibylline verses were paracrostics. *See* ACROSTIC.

PARACYA'NOGEN. When cyanuret of mercury is decomposed by heat, a brown solid matter remains having the same composition as gaseous cyanogen, hence designated as above.

PARA'DE. (Fr.) The place where troops draw up to do duty, mount guard, &c. The original meaning of the word is *show* or *ostentation;* and it is used as above, because on these occasions officers and men are expected to be in full uniform, or completely equipped.

PA'RADIGM. (Gr. παραδειγμα, *an example*.) In Rhetoric, a general term, used by Greek writers in the sense of "example," or "illustration," of which "parable" and "fable" are species. (*Quintilian*, v. 2.) Hence, in early theology, those writers who narrated the lives of religious persons, by way of examples of Christian holiness, were styled Paradigmatics.

PA'RADISE. (Gr. παραδεισος: said to be derived from a Persian or Chaldaic word, or from the Arabic firdauz, *a fruitful valley*.) This name, of oriental origin, was used by the Greek historians to denote the extensive parks or pleasure grounds of the Persian monarchs. (Xenophon, *Cyrop.* and *Œconom.; Diod. Sic.* xvi. 41., xviii. 36.; described by *Quintus Curtius*, viii. 1., who does not use the word. See also *Aulus Gellius*, ii. 20.) The Septuaginta have employed the word in their translation of Genesis, ii. 8., to signify the abode in which Adam and Eve were placed by their Creator. It also occurs in other parts of their translation. (Numbers, xxiv. 6.; Genesis, xiii. 10.; Ez. xxviii. 13., xxxi. 8.) It is used in the N. T., in the memorable passage, Luke, xxiii. 43. The speculations into which this mysterious passage has led learned and pious men, in all ages of the church, form too extensive a subject to be entered upon here. The mythologies of many nations contain similar ideas, whether derived from the ancient tradition of a paradise, or formed out of the inherent sense of man of his own imperfection and longing after a better state, from which he imagines himself to have fallen. (See, especially, the first part of *Buttmann's Mythologus*, and *Bryant's Mythology*.) The rabbis have formed, as usual, a strange collection of legendary tales out of the simple narrative of Scripture. According to them, there is an upper or heavenly, and a lower or earthly paradise. The lower is situated somewhere under the terrestrial equator. Each is divided into seven dwellings, and each of these is twelve times 10,000 miles in length and breadth. A column ascends from the lower to the upper heaven, by which the souls of the blessed mount after a temporary sojourn in the former. A wall of partition divides paradise from hell; and this will fall when the Redeemer comes, and all Israel be gathered together in blessedness.

The celestial paradise is generally referred to as identical with heaven, or the place of bliss hereafter. Some critics, who weigh very nicely our Lord's expression in addressing the penitent thief, "To-day shalt thou be with me in paradise," have imagined the existence of a distinct abode for the souls of the just before the final judgment. When we consider, however, that, upon the authority of another passage in Scripture, we affirm that our Saviour went down into hell between his death and resurrection, it will be better, perhaps, not to affix too definite a meaning either to the one expression or the other.

The local situation of the terrestrial paradise has been a favourite subject of speculation, both with the fathers of the church and with later inquirers. The reader may consult, if he will, the first volume of the compilation called the *Ancient Universal History*, where the matter is seriously discussed at great length; he will also find it treated in an entertaining article of the *Enc. Metropolitana*. (See also Schulthess, *Das Paradies*, Zurich, 1816.) The most ordinary opinion has placed it on the Euphrates and Tigris. Josephus regards the Pison

mentioned in Genesis as the Ganges, the Gihon as the Nile. Hardouin places his in Palestine. Huet (*De la Situation du Paradis Terrestre*, 1691) enumerates a variety of these theories. The paradise of the Moslems is termed in the *Koran* Gannath, or the Happy Gardens; and its description is evidently borrowed from the notions of the rabbis and oriental Christians. See, chiefly, chapters lv. lvi.; but these passages, although flowery enough, contain a very small part of the extravagances, chiefly drawn from tradition, which make up the vulgar Mohammedan notion of paradise. (See, in addition to the authorities already cited, a learned article in the unfinished *Encyclopædia* of Ersch and Gruber.)

PA'RADOX. (Gr. παραδοξος, *contrary to received opinion.*) A term applied to any proposition which seems to be absurd, or at variance with common sense, or to contradict some previously ascertained truth; though, when properly investigated, it may be found to be perfectly well founded. The reader will find in Bishop Horsley's 19th Sermon the nature of a paradox, and the points wherein it differs from a contradiction, clearly illustrated.

PARADO'XUS. (Gr. παραδοξος, *wonderful.*) A name devised to express the obscure nature of a genus of Trilobites (fossil Crustaceans), to which it is attached, and which is characterized by the absence or indistinct nature of the prominent even-formed eyes which are borne on the shield of all other Trilobites. The segments extend beyond the sides of the body, and are free at their lateral extremity. It serves also as a specific name for obscure and anomalous animals; as the *Ornithorhynchus paradoxus*, *Lepidosiren paradoxa*, &c.

PA'RAFFINE. A substance contained in the products of the distillation of the tar of beech wood. It is a tasteless inodorous fatty matter, fusible at 112°, and resists the action of acids and alkalis. It appears to be a hydro-carbon. Its name is compounded of parum, *little*, and affinis, *akin*, to denote the remarkable chemical indifference which is its characteristic feature. A similar substance has been obtained by Dr. Christison from the petroleum of Rangoon.

PARA'GIUM. (Lat. par, *equal.*) In Feudal Jurisprudence, the body of nobles (peerage) was so termed; the word likewise expressed equality of condition in various legal relations, as, for example, between the lords in partnership of a fief. Parage was also a custom by which the elder of several coheirs of a fief rendered homage for the whole, and thereby guaranteed the enjoyment of it to his coheirs as well as himself; in the same manner, one of several copurchasers might be admitted to a similar privilege.

PARAGO'GE. (Gr. παρα, *by the side of*, and αγω, *I bring.*) In Grammar, a figure by which one or more letters are added at the end of a word; *e.g.* in the ordinary formation of diminutives in most languages. *See* METAPLASM.

PARAGO'GIC LETTERS. (Gr. παραγωγη, *an addition.*) In the Semitic languages, letters which, by their addition to the ordinary form of the word, import additional emphasis, or some peculiar inflexion into the sense. Their real meaning and authority have been much debated among Hebrew scholars.

PA'RAGRAPH (Gr. παραγραφος), ordinarily signifies a small subdivision of a connected discourse, and is indicated by the sign ¶ in modern orthography.

Parágraphe, as used by Greek rhetorical writers, is a poetical figure employed when the writer sums up in a few words the substance of a previous passage, by way of transition to a new one. It was probably so called by analogy. (*Eustathius on Hom. Il.* i. 304.)

PARALEI'PSIS. (Gr. παραλειπω, *I omit.*) In Rhetoric, the artificially exhibited omission or slight mention of some important point, in order to impress the hearers with indignation, pity, &c., called by the Latins præteritio, omissio, &c.; as in the famous lines —

> Occidat illa dies ævo, nec postera credant
> Sæcula: nos certe, taceamus, et obruta multa
> Nocte tegi nostræ patiamur crimina gentis.

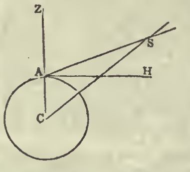
The passage, Hebr. xii. 32., may be given as another instance; or the following from Cicero: — "Præterco illum nefarium conatum tuum," &c. (*Conc. c. Antonium.*)

PARALIPO'MENA. (Gr. παραλειπόμενα, *things left out or aside.*) A term applied, in Bibliography, to works of a supplementary character. The two books of the Old Testament called by us, after Saint Jerome, the Chronicles, are also termed Paralipomena.

PARALLA'CTIC INSTRUMENT. An astronomical instrument for determining the moon's parallax, described by Ptolemy in his *Almagest*, and usually called *Ptolemy's Rules*. The term *parallactic* is sometimes applied to the equatorial; but in this sense the proper word would seem to be *parallatic*, as derived not from *parallax*, but from *parallel*, the instrument being constructed for the purpose of following the stars in their diurnal parallels. (Lalande, *Astronomie*, § 2278.)

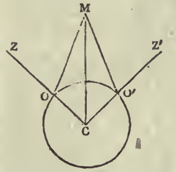
PA'RALLAX. (Gr. παραλλαξις, *change.*) A change of place or of aspect. The term is used in astronomy to denote the difference between the *apparent* place of a celestial object and its *true* place, or that in which it would be seen if the observer were placed at the centre to which the motion is referred. When the point of reference is the centre of the earth, the change of aspect is called the *diurnal parallax*; when it is the centre of the earth's orbit, the change is called the *annual parallax.*

Diurnal Parallax. — Let C be the centre of the earth, A the place of the observer, Z his zenith, and S a celestial body. On observing the body from A, it will be seen in the direction A S, making the angle Z A S with the zenith. But if the observer could be placed at C, he would see the body in the direction C S, making the angle Z C S with the zenith. The difference between these two angles Z A S and Z C S is the parallax of S, which, therefore, is equal to the angle A S C. Hence it appears that the parallax of a celestial body is the angle comprised between two lines drawn from the body, the one to the centre of the earth, and the other to a point on its surface. On account of the immense distance of the fixed stars, the diurnal parallax is altogether insensible with regard to them. It may amount to a degree in respect of the moon; but the greatest parallax of the nearest planet does not exceed 30″.



It is evident, from the inspection of the figure, that although the distance of the object S remain the same, the angle A S C is not a constant quantity, but is greatest when S is seen in the direction of the horizon A H, and diminishes as the altitude of S increases, until it vanishes altogether at the zenith, where the two lines A S and C S merge into the line C Z. In order to discover the law of this variation, let $a =$ C A, the semidiameter of the earth; $d =$ C S, the distance of the observed object from the centre; Z = Z A S, the apparent zenith distance; and P = A S C, the parallax. Now, the sides of a triangle being in the same proportion as the sines of their opposite angles, we have $d : a :: \sin. Z : \sin. P$, whence $\sin. P = \frac{a}{d} \sin. Z$. But as P is always a very small angle, the arc may be substituted for the sine without sensible error, and the formula becomes $P = \frac{a}{d} \sin. Z$; that is to say, the parallax is proportional to the sine of the zenith distance. At the horizon Z is a right angle, and sin. Z = 1: in this case, therefore, the expression for the parallax becomes $P = \frac{a}{d}$. This is called the horizontal parallax; and when its amount has been determined by any means with respect to a celestial body, the parallax of the body at any altitude is found by multiplying the horizontal parallax by the cosine of the altitude, or sine of the zenith distance.

Since the parallax of a body is given in terms of its distance and the earth's semidiameter, it follows, reciprocally, that the distance of the body is given in terms of its parallax. The determination of the parallaxes of the different bodies of the solar system is therefore a problem of great importance in astronomy; but it is attended with considerable difficulty in practice, although the principle on which it depends is extremely simple. It may be described as follows: — Let two observers be stationed at the points O and O′, of which the latitudes are supposed to be known, and which are both situated on the same meridian, and let them simultaneously observe the zenith distances of the body M (suppose the moon). These observations will give the angles Z O M and Z′ O′ M, and, consequently, M O C and M O′ C. The angle O C O′ is also known, being the difference or the sum of their latitudes, according as they are on the same or opposite sides of the equator. But the two sides C O and C O′ of the quadrilateral M O C O′, being radii of the earth, are also supposed to be known; hence the quadrilateral is determined, and its diagonal C M may easily be computed by the rules of plane trigonometry. But when C M is found, the horizontal parallax is also determined, being equal, by what has been already shown, to the quotient obtained by dividing the radius C O by the distance C M. In this manner the horizontal parallax of the moon was determined by Lacaille and Lalande; the former observing at the Cape of Good Hope, and the latter simultaneously at Berlin. There are methods, however,



by which the lunar parallax may be determined by observations made at a single place.

The moon's mean horizontal parallax amounts to 57′ 4″·17, or ·95116 of a degree. In respect of all the other bodies of the solar system the parallax is an extremely small quantity, and, excepting perhaps in the case of Mars, cannot be determined by the method now described with sufficient precision and certainty. That of the sun, the most important of all, is most accurately found by observations of the transits of Venus over his disk, as was first suggested by James Gregory, in his *Optica Promota*. It amounts only to 8·6″; whence we infer that the mean distance of the sun from the earth is 23·984 times the length of the earth's radius, or about 95,000,000 miles. (*See* SUN.) This determination suffices for finding the parallaxes and distances of all the planets in the system; for in consequence of the relation established by Kepler's third law between the distances and periodic times, when the distance of any one planet from the sun is known that of every other can be deduced from the times of revolution. (See *Kepler's Laws*.)

When the parallax of a celestial body has been determined, we can find not only the distance of the body, but also its diameter and real magnitude. For the apparent diameter being found by observation, the true magnitude is given by this proportion: — The horizontal parallax is to the apparent radius, as the radius of the earth to the true radius of the body.

The effect of parallax is to depress the observed body in the vertical circle, or to increase its zenith distance. If the body at the time of the observation is on the meridian, the parallax only affects its declination; but if it is not on the meridian, the observed right ascension and declination are both altered, and the effect on each of these co-ordinates must be computed from the previously known horizontal parallax by the rules of spherical trigonometry. The computation, in the case of the moon, is considerably complicated by the earth's ellipticity.

Annual Parallax. — In what has yet been said the centre of the earth has been taken as the point of reference, and therefore regard has only been had to the difference of apparent situation occasioned by the eccentric position of the observer at the surface of the earth. But the sun, and not the earth, may be regarded as the centre to which the motion is referred; and the position of any celestial body of which the distance from the sun is not so great as to be incomparable with the semidiameter of the earth's orbit, would be different if viewed from the sun from what it is when viewed from the earth. This difference is called the *annual parallax*, or *parallax of the great orb*. It is the angle under which the semidiameter of the earth's orbit would be seen from a superior planet, or from a fixed star. Such, however, is the enormous distance even of the nearest fixed stars, that excepting two or three instances, which perhaps may be still regarded as doubtful, not one of them has yet been discovered to be sensibly affected by annual parallax; though observations have been carried to such nicety that did the quantity in question amount to a single second, it could not possibly have escaped detection.

From observations of right ascension and declination, Piazzi deduced a parallax of 4″ for Sirius, and of 5·7″ for Procyon, and Calandrelli one of 4″ for α Lyræ; but these determinations have been proved to be erroneous. Dr. Brinkley conceived that his observations with the Dublin circle indicated a sensible parallax in the three stars, α Lyræ, α Cygni, and α Aquilæ; but Mr. Pond showed that no sensible parallax in any of these stars could be deduced from the Greenwich observations, and Mr. Airy has confirmed this conclusion in respect of α Lyræ. Mr. Henderson, however, has found a probable parallax in the star α Centauri from his observations made at the Cape of Good Hope. Sir William Herschel first pointed out the micrometrical measurements of the distances of two stars very close to each other, or nearly in the same line of vision, as a likely method of detecting parallax; for the apparent distance between two such stars, if either has a sensible parallax, must vary at different times of the year; and this method has very recently been applied by Struve, at Dorpat, to α Lyræ, and by Bessel, at Konigsberg, to the double star 61 Cygni. The results obtained by the latter are the most unequivocal. By a series of observations with the heliometer, continued from August, 1838, to March, 1840, Bessel obtained the value of the parallax = 0·348″, a little more than the third of a second of space. Assuming this determination, and astronomers seem to regard it as established within certain small limits, the distance of the star from the earth must be 519,200 times the sun's distance, — a distance so enormous that light, which travels at the rate of 192,000 miles in a second, would require 9¼ years to pass through it. (*Monthly Notices of the R. Astr. Soc.* for May, 1840. For the history of researches on the subject of the annual parallax, see *Mem. R. Astr. Soc.* vol. xii.) *See* STAR.

PARALLE′LEPIPED (Gr. παραλληλ-επιπεδον), frequently, but incorrectly, written *Parallelopiped*. A solid contained by six planes, three of which are parallel to the other three. The content of this solid is found by multiplying the area of one of its faces by its distance from the opposite face. Consequently, parallelepipeds on equal bases, and of the same height, are equal.

PA′RALLEL LINES, in Geometry, are defined by Euclid to be "straight lines which are in the same plane, and, being produced ever so far both ways, do not meet."

The subject of parallel lines is one of the most difficult in the elements of geometry, and has accordingly given rise to much learned discussion. The difficulty consists in demonstrating that two parallel lines, when they meet a third line, are equally inclined to it, or make the alternate angles with it equal. In order to demonstrate this proposition, Euclid assumes as an axiom that "If a straight line meet two straight lines, so as to make the interior angles on the same side of it less than two right angles, these straight lines, being continually produced, will at length meet on the side on which the angles are which are less than two right angles." But this is not a self-evident truth: it is, in fact, a proposition which requires to be demonstrated; and the converse of it, namely, that two straight lines which meet one another make with any third line the interior angles less than two right angles, forms the 17th proposition of Euclid's first book. Geometers have attempted in many different ways, but without complete success, to remove this blemish from the Elements. The methods which they have employed for this purpose are of three kinds: 1. By adopting a new definition of parallel lines; 2. By introducing a new axiom; 3. By reasoning merely from the definition of parallel lines and the properties of lines already demonstrated.

Some geometers, among whom are Wolfius, Boscovich, and Thomas Simpson, have adopted the following as the definition of parallel lines; namely, that "straight lines are parallel which preserve always the same distance from each other;" but this, like Euclid's definition, as remarked by D'Alembert, is begging the question. The correct definition would be, that "two straight lines are parallel when there are two points in the one from which the perpendiculars drawn to the other, and on the same side of it, are equal." The difficulty then consists in demonstrating that *all* the perpendiculars drawn from the one of these lines to the other are equal. Another definition, which has been adopted by Varignon, Bezout, and others, is, that "parallel lines are those which make equal angles with a third line towards the same parts, or make the exterior angle equal to the interior and opposite." When this definition is adopted, the difficulty consists in proving that straight lines which are equally inclined to one *given* straight line must be equally inclined to *all* the other straight lines which fall upon them.

Of the new axioms which have been substituted in place of Euclid's, we shall merely notice that given by Thomas Simpson, in the second edition of *Elements;* namely, that "If two points in a straight line are posited at unequal distances from another straight line in the same plane, those two lines, being indefinitely produced on the side of the least distance, will meet one another." By help of this axiom he proves that if two straight lines are parallel, the perpendiculars to the one terminated by the other are equal, and also perpendicular to the other parallel; and thence the proposition from which all the rest follows, namely, that if a straight line fall on two parallel lines, it makes the alternate angles equal. Playfair remarks on this method, that it is extremely plain and concise, and perhaps as good as any that can be followed when a new axiom is assumed.

Legendre, in his *Elements of Geometry*, has attempted to overcome the difficulty of parallel lines by previously demonstrating that all the angles of a triangle are equal to two right angles, from which proposition it is easy to prove every thing with respect to parallels. His demonstration, however, is of too refined and subtle a kind to be admissible into the Elements. (See the Notes to *Playfair's Euclid*, *Legendre's Geometry*, and *Leslie's Geometry*. But the reader who wishes to have a complete view of what has been written on this subject should consult a learned *excursus* to the first book of *Camerer's Euclid*, Berlin, 1825; and also *Colonel P. Thomson's Geometry without Axioms*.)

It may be remarked, that the whole of the difficulty which exists with respect to the doctrine of parallel lines is of a metaphysical rather than of a mathematical kind; and the learner need not perplex himself about subtleties which can hardly be considered as affecting the rigour of geometrical truth.

PARALLE′LOGRAM. (Gr. παραλληλογραμμα.) A plane four-sided figure, of which the opposite sides are parallel. The area of a parallelogram is found by multiplying the length of one of its sides by that of the perpendicular let fall upon it from the opposite side. Hence parallelograms on equal bases, and of the same altitudes, are equal.

PARALLEL PLANES, are such as never meet, though indefinitely produced.

PARALLEL RULER. A mathematical instrument,

formed of two equal rulers connected by two cross bars or blades moveable about joints, so that, while the distance between the two rulers is increased or diminished, their edges always remain parallel; and consequently if the edge of one of the rulers be applied to a straight line, a parallel straight line may be drawn along the edge of the other ruler.

PARALLEL SAILING, in Navigation, is sailing on a parallel of latitude, or circle parallel to the equator. *See* NAVIGATION.

PARALLELS OF ALTITUDE, in Geography, are small circles of the sphere parallel to the horizon; also called *almacantars*.

PARALLELS OF DECLINATION. In Astronomy, small circles of the sphere parallel to the equator.

PARALLELS OF LATITUDE, on the Terrestrial Sphere, are small circles parallel to the equator; but, in the Celestial Sphere, they are parallel to the ecliptic.

PARALLEL SPHERE, in Geography, is that position of the sphere in which the equator coincides with the horizon, and the poles are in the zenith and nadir. This is the appearance which the sphere would have to a spectator placed at the pole. The stars neither rise nor set, but move constantly in circles parallel to the horizon; and the sun rises and sets only once a year.

PARA'LOGISM. (Gr. παρὰ, *beside*, and λόγος, *reason.*) In Logic and Rhetoric, a reasoning which is false in point of form; *i.e.* in which a conclusion is drawn from premises which do not logically warrant it. It is the opposite to a syllogism or correct logical deduction. *See* SYLLOGISM.

PARA'LYSIS. (Gr. παραλυω, *I weaken.*) Palsy. A diminution or loss of power of any part of the body. In general one side only is affected, or the upper or lower extremities. Whatever debilitates the system may produce palsy; it is also produced by pressure upon certain parts of the brain and spinal marrow, and occasionally by poisons, by local injuries, and by the sudden suppression of certain evacuations. It frequently produces a distortion of the mouth or eye, the speech becoming indistinct, and the judgment often impaired. The treatment of palsy depends upon a careful consideration of its cause; more or less depletion is generally required, together with purges and nervine stimulants, such as ammonia, &c., and blisters to the head and neck.

PARA'METER. In Geometry, a constant straight line belonging to each of the three conic sections; otherwise called the *latus rectum*. In the parabola, the parameter is a third proportional to the absciss and its corresponding ordinate; in the ellipse and hyperbola, the parameter of a diameter is a third proportional to that diameter and its conjugate. The term is also used in a general sense, to denote the constant quantity which enters into the equation of a curve.

PARA'MO. (Sometimes rendered, though incorrectly, by *desert* or *heath.*) The name given in South America to a mountainous district covered with stunted trees, exposed to the winds, and in which a damp cold perpetually prevails. Under the torrid zone, the Paramos are generally from 10,000 to 12,000 feet in height. Snow often falls on them, but remains only a few hours; in which respect they are distinguished from the *Nevados*, which enter the limits of perpetual snow. The Paramos are almost constantly enveloped in a cold thick fog; so that when a thick small rain falls, accompanied with a depression of the temperature, they say at Bogota, or at Mexico, *cae un paramito*. Hence has been formed the provincial word *emparamarse*, — to be as cold as if one were on a *paramo*. (*Humb. Pers. Nat.* ii. p. 252.)

PA'RANA'PHTHALINE. A substance so termed from Gr. παρα, *near to*, because it closely resembles *naphthaline*. It appears to be a mixture of paraffine and naphthaline.

PARA'NTHINE. A rare mineral, so named by Haüy; the same as *Scapolite*.

PA'RANYMPH. (Gr. παρανυμφος.) A bridesman. It is translated in our version of the Scriptures by "master of the feast."

PA'RAPET, or BREAST-WORK. (Ital. parapetto, *breast-work.*) In Fortification, a wall or screen raised on the extreme edge of a rampart or other work, through which embrasures or openings are cut for the cannon to fire through. The solid parts of the parapet, between the embrasures, are called the *merlons*. In common language, a parapet is a breast-wall, raised on the edges of bridges, quays, &c. to prevent people from falling over.

PA'RAPH. (Gr. παρα, and ἁπτω, *I touch.*) In Diplomatics, the figure formed by a flourish of the pen at the conclusion of a signature. This formed, in the middle ages, a sort of rude provision against forgery, like the flourishes in the plates of bank notes. In some countries (as in Spain) the paraph is still a usual addition to a signature.

PA'RAPHERNA'LIA. (Gr. φερνη, *a dowry.*) In the Civil Law, the apparel, jewels, &c. of a wife, which are held to belong to her as a species of separate property. The husband may dispose of them in her lifetime, but cannot bequeath them away from her; and if he have not parted with them before his death, she may retain them against his executors and all other persons, except his creditors, where his other funds are not sufficient to satisfy their claims.

PARAPHO'NIA. (Gr. παρα, and φωνη, *voice.*) Alteration of voice.

PA'RAPHRASE. (Gr. παρα, *beside*, and φράζω, *I speak.*) In Rhetoric, the rendering of a passage or portion of writing in other phraseology, more distinct and easier of explanation, and therefore usually at greater length. A loose translation, or one in which a new series of ideas and illustrations conveying the same general meaning with those of the original is substituted for them, is also termed a paraphrase, although not with strict propriety.

PARAPHY'SES. (Gr. παρα, and φυσις, *nature.*) A term used in describing mosses, to denote the sessile ovate abortive bodies placed below the theca.

PARAPLE'GIA. (Gr. παραπλησσω, *I strike inharmoniously.*) Palsy of the upper or of the lower half of the body.

PA'RASANG. (Gr.) A Persian measure of length; according to Herodotus, equal to 30 stadia, and (reckoning 8 stadia to the English mile) equal to 3¾ English miles. The length of the parasang was reckoned differently by different authors; and such are the discrepant estimates of the ancients that some have assigned it the length of 60 stadia. The word is supposed to be derived from the Persian seng, signifying *a stone*.

PARASCE'NIUM. (Gr. παρα, and σκηνη, *a scene.*) In Antiquities, called also *postscenium*, the back part of a theatre beyond the stage, or the room to which actors withdrew on quitting the stage. It was equivalent to the modern *green room*.

PA'RASITE. (Gr. παρα, *at hand*, and σιτος, *food.*) Originally, according to Crates in Athenæus, a term of honour, being the appellation of certain ministers at sacrifices, whose office is not distinctly ascertained. (See *Mem. de l'Acad. des Inscr.* vol. xxxi.) The habits of a luxurious age produced the race of poor companions, ready guests at the table of a patron, who formed a standing character in the later Greek comedy. Some attribute the first conception of the dramatic personage to Araros, the son of Aristophanes. Diphilus, according to Athenæus, gave the most complete portrait of it in his comedy *Telesias*. Our notions of the ancient parasite are now derived chiefly from the Latin comic poets. Ingenious writers have divided parasites into four classes: — 1. The poor confidential friend, whose services to his patron are sometimes rendered with a mixture of real attachment, as in the character of Ergasilus in the *Captives* of Plautus. 2. The guest who is invited with a view to make him pay for his reception by the exertion of his powers of entertainment (Anglicè diner-out), the "ridiculi" and "derisores" of Plautus, and who alone are described under the name of parasites by Julius Pollux: Vibidius and Balatro, the two umbræ of Mæcenas at the supper of Nasidienus, seem to have partaken of this quality. These degenerated, thirdly, into the class of mere buffoons, who were invited to play tricks and undergo practical jokes, under pain, as Ergasilus complains, in the play already cited, if they refused to lend themselves to the manual pleasantries of their guests, of "taking up their beggar's wallet and marching." The fourth and worst class, κολακες, were the attendant flatterers of their patron. Such is Artotrogus, or Loaf-eater, the humble companion of Pyrgo-Polinices in the *Miles Gloriosus* of Plautus; and the best known of all parasites, Gnatho, in the *Eunuch* of Terence.

PA'RASITES. In Zoology, this term, as designative of a group of animals, is variously applied by different naturalists. Lamarck includes under it a family of antennated Arachnidans; Cuvier, Latreille, and Kirby apply the term to an order of Apterous insects; Straus to a tribe of Crustaceans: but all the sections include animals of parasitic habits.

PARASITI'CAL PLANTS, are those which grow into the tissue of other species, and feed upon their juices. Of this kind are the misletoe, the broom rape (*Orobanche*), the *Lathræa;* and, among exotics, the monstrous *Rafflesia*. Such species have no proper roots. The term *parasitical* is, however, often applied to mosses, Orchidaceous plants, Tillandsias, and the like, which are mostly Epiphytes, growing upon the bark of trees, but deriving their food from the air by means of their own roots.

PARA'STATÆ. (Gr. παρα, *from*, and ἱστημι, *I stand.*) In Architecture, pilasters, or rather square pillars, which stand insulated. *See* ANTA.

PA'RATA'XIS. (Gr. παρατασσω, *I arrange side by side.*) In Grammar, opposed to Syntax. The mere ranging of propositions one after another, as the corresponding judgments present themselves to our mind, without marking their dependance on each other by way of consequence or the like.

PA'RBUCKLE. In Naval language, to roll a cask

or any cylindrical body by pulling upon ropes fastened towards the place where the cask is to go, and laid along the ground or an inclined plane, and then over the ends or quarters.

PA'RCÆ. The Latin name of the Fates. According to Klausen (art. "Parcæ," in the *Encyclopædia* of Ersch and Gruber), the original Roman Parca (the harsh or avaricious goddess) was equivalent to Mors, the goddess of death, the third of the Fates. It was not until the Augustan age, when the Greek and Roman mythology became mingled, that the Parcæ became plural (*Virg. Ec.* iv. 47.), and acquired their similarity to the Greek Moirai, Clotho, Lachesis, and Atropos.

PARCEL A ROPE. In Naval language, to cover it smoothly with tarred canvass, which is then bound over with spun-yarn.

PARCENERS. In Law. *See* COPARCENERS.

PA'RCHMENT. (Fr. parchemin.) A material formed of the prepared skins chiefly of sheep and goats, when intended to be written upon. A similar preparation of calves', kids', and lambs' skins is called *vellum*. The skins are first prepared as for tanning; then shaved down and pumiced; and lastly, stretched and carefully dried. The parchment of drums is made of the skins of asses, calves, and wolves; ass skin is used for battledores; and goat skin is preferred for sieves. For some kinds of bookbinding parchment is dyed green by verdigrease. (See *Ure's Dictionary of Arts*.)

Parchment was known at a very early period. It was used for writing as early as the year 250 before the Christian era by Eumenes, king of Pergamus; who, desirous of collecting a library which should vie with that of Alexandria, but prevented by the jealousy of the Ptolemies from obtaining a sufficient quantity of papyrus, had recourse to this substitute; and its invention at Pergamus claimed and secured to it the lasting name of Pergamena: whence *parchment*. (*Sir G. Wilkinson's Manners and Customs of the Ancient Egyptians*, iii. 151.) In the beginning of the eighth century, the use of the papyrus was almost entirely superseded by parchment, on which we find that all the public documents under Charlemagne and his dynasty were written. When the different kinds of parchment came into use for the purposes of writing, they were rolled up before they could be sealed: hence the word *volumen*, from Lat. volvere, *to roll*. And as parties wrote to the very bottom of the parchment, *i.e.* to the place where the cord used for the folding was fastened, we may account for the well-known expression, *opus ad umbilicum perductum*.

PA'RDON. In Law, it is part of the prerogative of the crown to pardon all offences merely against the crown or the public, excepting the offence of committing any person to prison out of the realm, which, by the Habeas Corpus Act, is made a præmunire, unpardonable even by the king: and excepting those offences in the prosecution of which private justice is in some measure concerned, as nuisances and offences against a popular or penal statute after information; for thereupon the informer has a private property in his part of the penalty. Pardon is granted under the great seal, or by warrant under the sign manual, countersigned by one of the principal secretaries of state; or by act of parliament. Its effect is, in almost all cases, to make the offender a new man, and to discharge him from all the penal consequences attaching to his offence.

PARE'CBASIS. (Gr. παρα, and εκβαινω, *I go out of*.) The word used by Greek authors to signify what by the Latins is called digression; by *Quintilian* (iv. 14.) termed "alienæ rei, sed ad utilitatem causæ pertinentis, extrâ ordinem occurrens tractatio."

PAREGO'RIC. (Gr. παρηγορεω, *I assuage*.) That which allays pain. *Paregoric elixir* is a camphorated tincture of opium flavoured by oil of aniseed.

PAREI'RA BRA'VA. The root of the *Cissampelos pareira*, brought from South America. It has a sweetish and a bitter flavour, and has been used in nephritic complaints and some affections of the bladder.

PARE'LLA. In Botany, a kind of lichen; the *Lecanora parella*, found on rocks in mountainous countries, especially in the north of Europe. It is the *Perelle* of Auvergne, where it is extensively used by the dyer, and is found equal to orchil (*Rocaila tinctoria*).

PARE'MBOLE. (Gr. παρα, and εμβαλλω, *I throw in*.) In Rhetoric, a figure by which a paragraph is inserted in the middle of a sentence with which it does not grammatically cohere, by way of explaining something. It is also called *paremptosis*, and is a species of parenthesis.

PARENCHY'MA. (Gr. παρεγχυειν, *to strain through*.) The spongy and cellular tissue of animals and vegetables. The old physiologists supposed that the crude juices underwent a kind of filtration in the cellular substance.

PARENCHY'MATOUS ENTOZOONS, *Parenchymatosa*. (Gr. παρεγχυμα.) An order of Entozoa, including those which have their nutrient canals simply excavated in the parenchymatous tissue of which their entire body is composed. *See* STERELMINTHA.

PARE'NTHESIS. (Gr. παρα and εν, and the verb τίθημι, *I place*.) In Rhetoric, a figure by which a series of words is inserted in a sentence, having no grammatical connection with those which precede or follow, with the object of explaining some detached portion of the sentence. In ancient authors, a parenthetical form of writing is even more common than among moderns; because much which a Greek or Roman author would have conveyed by way of parenthesis is now inserted in separate explanatory notes.

PA'RGASITE. A variety of actinolite, from Pargas in Finland.

PA'RGET. (Etymology uncertain.) In Architecture, the plaster formed of lime, hair, and cow-dung, used for coating the flue of a chimney.

PARHE'LION, or MOCK SUN. (Gr. παρα, and ἥλιος, *the sun*.) A meteor which consists in the simultaneous appearance of several suns, "fantastic images of the true one." These images appear at the same height above the horizon as the true sun, and they are always connected with one another by a white horizontal circle or halo, of which the pole is at the zenith, and the apparent semidiameter equal to the sun's distance from the zenith. The images or mock suns, which appear on the same side of this circle with the true sun, are tinted with the prismatic colours, and sometimes a part of the circle itself contiguous to them appears coloured. But those which appear on the circumference opposite to the sun are always without colour; whence it may be conjectured that these (as well as the luminous ring itself) are produced by reflection, and the others by refraction. In general, when these phenomena are produced, the sun is surrounded by one or more concentric circular coronæ which exhibit the colours of the rainbow; and sometimes arcs of circles, or even entire circles, appear touching the coronæ. These also are coloured, and contain other parhelia. The phenomenon has been described by Aristotle, Pliny, Scheiner, Descartes, and many others; but the most perfect apparition yet recorded is that which was observed by Hevelius at Dantzic, on the 20th of February, 1661. It is represented in the annexed figure.

Parhelia have continued visible for two, three, or four hours. In general two, but sometimes four, and even six or seven, are visible together.

No very satisfactory explanation of the cause of these curious but rare phenomena has yet been given. Huygens supposed them to be produced partly by the reflection and partly by the refraction of the sun's rays, falling on an infinite number of small cylinders of ice suspended vertically in the atmosphere, and having certain determinate positions relative to the sun and the observer. This theory is explained at length in the second volume of his *Opera Posthuma*. (See also *Smith's Optics; Priestly on Light;* Biot, *Traité de Physique*, tom. iii.)

Fraunhofer, in a memoir on halos and parhelia, published in *Schumacher's Astronomische Abhandlungen*, p. iii., has attempted to explain these phenomena on a different principle. On looking at the sun through a horizontal grating of very fine wires, two images of the sun appear, one above and the other below the true sun; and, if there is some inequality in the distances between the wires, the images appear slightly coloured, and a vertical streak of light is seen. Fraunhofer thinks that this affords a clue to the theory of the parhelia; for if the small spherules of moisture floating in the atmosphere are disposed in horizontal parallel lines with tolerable regularity, two vertical parhelia (but this is a very rare phenomenon) will be seen; and if they are disposed in vertical lines, the more common phenomena of horizontal parhelia with the luminous circles may be produced. It must be confessed, however, that even when this arrangement of the particles of vapour in parallel lines is admitted, several circumstances attending the phenomena will still remain unexplained.

Parasclenæ, or images of the moon, are also seen under similar circumstances as parhelia: the same theory will of course apply to both.

PA'RIAN CHRONICLE. (So called from the island of Paros, where it was originally found.) The name given to one of the celebrated marbles imported into England with the rest of the collection known by the name of the Arundelian. In its perfect state it contained a chronological register of the principal events in the history of ancient Greece during a series of 1318 years, beginning with the reign of Cecrops, the first king of Athens, B. C. 1582, and ending with the archonship of Diognetus; but the last ninety years are nearly obliterated by the injuries of time, so that the part which now remains ends at the archonship of Diotimus, B. C. 354.

The marble on which the chronicle is engraved is 5 inches in thickness, and measured, when Selden viewed it, 3 feet 7 inches by 2 feet 7; but one corner had been broken off. It contained originally about 100 lines, each consisting on an average of 16 words, or 130 letters;

so that the whole might have been comprised in six octavo pages.

This venerable monument was purchased at Smyrna, with many others, by Mr. W. Petty, who was employed by the Earl of Arundel, in the year 1624, for the purpose of collecting marbles, books, statues, and other curiosities in Italy, Greece, and Asia Minor. When brought to England, in 1627, it was placed in the gardens belonging to Arundel House, the site of which is now occupied by Arundel, Norfolk, Surrey, and Howard Streets, in the Strand; and early on the following day it was examined, with eager curiosity, by some of the most distinguished literati of that time; among whom were Sir R. Cotton, Selden, Patrick Young, and Richard James. After much labour it was deciphered, and a copy of it published by Selden in the year 1628, accompanied with a Latin translation and commentary.

During the civil wars, and the subsequent usurpation of Cromwell, the Parian Chronicle was unfortunately broken into smaller fragments, and almost entirely defaced. The upper part, containing nearly half the original tablet, is said to have been used in repairing a chimneypiece or hearth in Arundel House; but luckily the inscription, or at least as much of it as could be made out, was preserved in the copy which Selden had previously taken and published. In the year 1667 the remaining fragments were presented by the Hon. Henry Howard, grandson of the first collector, to the University of Oxford, where they are now deposited.

The genuineness of this valuable relic of antiquity was universally acknowledged throughout Europe as soon as its contents were made known. Its authority was considered as equal, if not superior, to any other; writers of the first eminence derived the greatest advantage from it in their historical and chronological researches; and it was not till the year 1788, when the Rev. John Robertson, a gentleman of considerable learning and industry, published an elaborate volume called *A Dissertation on the Authenticity of the Parian Chronicle*, in which he maintained it to be a fabrication of modern times, that its authenticity was impeached. The doubts and objections of Mr. R. were founded on the following considerations: — 1. The characters have no certain or unequivocal marks of antiquity. 2. It is not probable that the chronicle was engraved for private use. 3. It does not appear to have been engraved by public authority. 4. The Greek and Roman writers, for a long time after the date of this work, complain that they had no chronological account of the affairs of ancient Greece. 5. This chronicle is not once mentioned by any writer of antiquity. 6. Some of the facts seem to have been taken from authors of a later date. 7. Parachronisms appear in some of the epochas, which we can scarcely suppose a Greek chronologer, in the 129th Olympiad, would be liable to commit. 8. The history of the discovery of the marbles is obscure and unsatisfactory; and 9. The literary world has been frequently imposed upon by spurious books and inscriptions, and therefore we should be extremely cautious with regard to what we receive under the venerable name of antiquity.

These observations were made the subject of separate chapters and disquisitions, and were illustrated with such candour and extensive erudition that for a short time the credit of the Parian Chronicle was shaken in the public opinion. Early, however, in the following year, the objections of Mr. Robertson were replied to by Mr. Hewlett, in a pamphlet entitled *A Vindication of the Authenticity of the Parian Chronicle*, Lond. 1789; by Mr. Gough, in the ninth vol. of the *Archæologia;* and by Porson, in the *Monthly Review;* and the result of their inquiries, coupled with the defence of Wagner (Gött. 1790), and the more recent investigations of Hales in his *Chronology*, and of Boeckh in the second volume of his *Corpus Inscriptionum*, leave no doubt respecting the authenticity and antiquity of the Parian Chronicle. It is impossible within our limits to give a detailed account of the manner in which these different writers have disposed of the arguments of Mr. Robertson; suffice it to say, that they have established satisfactorily that the Parian Chronicle is written in pure and classical Greek; that the characters bear several marks of antiquity; that the events it recounts are infinitely too minute and detailed to have been forged; and lastly, that the silence of classical writers respecting it (which is perhaps the strongest argument against its antiquity) may be easily accounted for from the retired and insular situation of Paros. (The reader will find in vol. i. of *Hales's Analysis of Chronology* an examination of the dates assigned to the different events recorded in the Parian Chronicle. See also the *Penny Cyclop.*)

PARIAN MARBLE. *See* MARBLE.

PA'RIAS. The lowest class of the inhabitants of some parts of Hindostan, who have, properly speaking, no caste, and are supposed to be descended from original races of occupiers long since conquered by foreign invaders. In the widest sense, the term appears to comprehend *all* the different classes of distinct non-Hindoo tribes, and degraded or foreign races, not comprised in the four Hindoo castes; forming, probably, nine tenths of the whole population, exclusively of the Mussulmans.

PARI'ETAL. (Lat. paries, *a wall.*) In Botany, any organ which grows from the sides of another. Those ovaries are parietal which grow from the sides of a calyx; and placentæ or ovules have this name when they proceed from the sides of the ovary.

PARIETAL BONES. Two arched and irregularly square bones, one on each side of the superior part of the skull. So called from paries, *a wall*, because they protect the brain like walls.

PAR-IMPAR. Among the Romans, the game of *even or odd*. The game was played exactly as it is at present among the children of our own country.

PA'RING AND BURNING. The operation of paring off the surface of worn-out grass land, or lands covered with coarse herbage, and burning it for the sake of the ashes, and for the destruction of weeds, seeds, insects, &c. Agriculturists differ as to the value of this mode of improving land; the greater number preferring a naked fallow even for one or two years, alleging that more injury is done by the vegetable matter lost in burning, than benefit obtained by the ashes produced. Where the object is to bring land abounding in coarse herbage immediately into a state of good culture, paring and burning is evidently the most rapid mode that can be employed; and if the soil contains calcareous matter, burning will have nearly the same effect on it as if a dressing of quicklime had been applied. Much, however, depends on the mode in which the land is treated afterwards.

PA'RISH. (Gr. παροικια, *a neighbourhood.*) Properly, an ecclesiastical division of a town or district subject to the ministry of one pastor. In the earliest ages of the church, the parochia was the district placed under the superintendence of the bishop, and was equivalent to the diocese. It denoted, says Bingham, not only what we now call a parish church, but a city with its adjacent towns or country regions. It was not until the Christians became sufficiently numerous to present distinct congregations in the smaller towns and villages that the bishop appointed his presbyters to reside among them, and thus subdivided his diocese into several parishes. This constitution is recognized in several councils and other monuments of the fifth century. It is, indeed, probable that in many cities there existed more than one church and congregation even in the time of the apostles; but it does not appear whether these deserved the name of parishes, as being each under the distinct superintendence of its respective pastor. But although parishes were originally ecclesiastical divisions, they may now be more properly considered as coming under the class of civil divisions; and consequently claim our attention under this head. It is not easy to determine the era of the division of England into parishes; they are mentioned in the laws of King Edgar so early as 970, when the whole kingdom seems to have been divided into parishes; but it is probable that the division was not made at once, but by degrees. It is, according to Blackstone, pretty clear and certain that the boundaries of parishes were originally ascertained by those of manors; for it very seldom happens that a manor extends itself over more parishes than one, though there are often many manors in one parish. The parochial division of England was nearly the same in the reign of Edward I. (1272—1307) as at present.

Parishes are frequently intermixed with one another. This seems to have arisen from the lord of the manor having had a parcel of land detached from the main part of his estate, but not sufficient to form a parish of itself. It was natural for him to endow the church which he had erected upon his principal estate with the tithes of these disjointed lands; especially if it happened that there was no church in any lordship adjoining to them.

The boundaries of parishes depend on immemorial custom; but it is probable that they were not settled with very minute precision till the introduction of the poor laws, when, in consequence of the claim for relief upon their particular parishes given to the poor, it became a matter of consequence to define exactly the limits of each parish. They cannot now be altered but by legislative enactment.

In the northern counties, where the parishes sometimes embrace thirty or forty square miles, the poor laws, the due administration of which must always depend on an intimate knowledge of the situation and character of every one applying for relief, could not be properly carried into effect. To remedy this inconvenience, an act was passed in the 13th of Charles II. permitting townships and villages, though not entire parishes, severally and distinctly to maintain their own poor. Hence townships in the north of England may be regarded as divisions subordinate to parishes, and are, in practice, as distinctly limited as if they were separate parishes.

Towns originally contained but one parish; but, from

the increase of inhabitants, many of them are now divided into several parishes.

Besides parishes, or townships, there are places which are deemed extra-parochial, or not within the limits of any parish. These were formerly the site of religious houses, or of castles, the owners of which would not permit any interference with their rights. At present they enjoy some most valuable privileges; among others, a virtual exemption from the poor's rate, because there is no overseer on whom the order of a magistrate may be served — from the militia laws, because there is no constable to make the return — and from repairing the highways, because there is no surveyor. Their tithes are, by immemorial custom, payable to the king instead of the bishop. The number of such places is not inconsiderable, amounting to more than 200. It seems highly inexpedient that any part of the country should enjoy such an exemption from burdens imposed for the benefit of the community. Extra-parochial wastes and marsh lands, when improved and drained, are assessed to all parochial rates in the parish next adjoining. In some counties, *liberties* interrupt the general course of law as affecting hundreds, in the same manner as extra-parochial places do with regard to parishes. This inconvenience is particularly felt in Dorsetshire. The number of parishes and parochial chapelries in England and Wales is not exactly ascertained; but there are not many doubtful cases, and for any general purpose they may safely be taken at 10,700. About 550 parishes extend into two counties, or into more than one hundred or other divisions. (*Blackstone's Commentaries*, Introd. § 4.; and *Preliminary Remarks to Census of* 1831, pp. 14—18.)

The parishes of Scotland are purely ecclesiastical: for an account of the system on which they are divided, we must refer the reader to the article PRESBYTERY.

PARISH CLERK. The name of one of the lowest functionaries of the English church. Parish clerks are regarded by the common law as persons having freeholds in their office; and consequently though they may be punished, they cannot be deprived, by ecclesiastical censures. In former times parish clerks were frequently in orders, and even at present this is sometimes the case. They are generally appointed by the incumbent, but by custom may be chosen by the inhabitants.

PARK. A considerable extent of pasture and wood land surrounding or adjoining the country residence of a man of wealth, devoted to purposes of recreation or enjoyment, but chiefly to the support of a herd of deer, though sometimes to cattle and sheep. Parks were originally nothing more than portions of forest scenery appropriated by the lord of the soil for the exclusive use of animals of the chase; but this is now become in many cases a secondary consideration, and the chief uses of a park are as indications of wealth and extent of territory, and as grazing ground for domesticated animals.

PARK OF ARTILLERY. An assemblage of the heavy ordnance belonging to an army, with its carriages, ammunition waggons, and stores, on ground contiguous to that occupied by the troops when encamped. *See* ARTILLERY PARK.

PA'RLIAMENT. (In modern Latin *parliamentum*, in French *parlement;* from the Fr. parler, *to speak.*) The supreme legislative assembly of Great Britain and Ireland.

Origin of Parliament. — By the principles of the feudal system, every sovereign and every great feudatory had his council, composed of his greater and lesser vassals, which occasionally assembled to assist him both in judicial and legislative matters; and which was held in theory to be permanent, so that its assent was necessary to the validity of his acts. And it was also an ancient custom, in several of the western kingdoms of Europe, for such potentates to hold assemblies of their barons at the great festivals of the year, termed *cours plenières* and *parlemens;* principally, however, if not entirely, for the mere purpose of show and magnificence. But occasionally such special assemblies were summoned for more important purposes; and the meeting in 1146, at which the crusade of Saint Louis was undertaken, is said to furnish the first occasion in which the word parliament is used for a deliberative assembly. In France, however, the word was afterwards transferred to signify the principal judicial courts of that country. (*See* PARLIAMENT.) The only realms in which it appears to have become appropriated to the great legislative assemblies are England, Scotland, and the Norman kingdom of Sicily. The parliament of the latter country consisted, in the 13th century, of spiritual and temporal barons summoned by the king's writ; and occasionally, but not uniformly, of deputies from the towns similarly summoned.

All the extensive and laborious researches which have been made, of late years, towards dispelling the obscurity which rests over the commencement and early constitution of our parliaments, have only shown that little new information is attainable on the subject. We can, indeed, conjecture pretty accurately the process by which meetings of delegates for the purpose of apportioning taxation became gradually assemblies, granting or refusing supplies with absolute authority; and that by which a convention summoned for the object of representing grievances to the sovereign, and giving their approbation to his acts, became a sovereign legislative body. But to investigate the internal changes in the assembly itself, the mode by which it became divided into distinct chambers, the manner in which the peerage was formed as a distinct body out of the free baronage of the country, and that in which the lower house acquired the features of a regular representative body, may be safely pronounced, with our present knowledge, impossible.

The Norman and Plantagenet kings had two councils, — the great council of the kingdom, and the lesser or privy council; and it may be freely stated, after making all deductions from the principle on the score of arbitrary powers occasionally exercised by the sovereign, that, ever since the Norman conquest, the supreme legislative power in England has been placed in the king and great council conjointly. It was, moreover, in early times, a court of criminal judicature also, and aided the sovereign in all the more important transactions of his government. It interfered even in matters of ecclesiastical discipline; in questions of peace and war, of grace and justice; and, by way of advice, in the appointment to vacant offices, civil or ecclesiastical. The meetings of the great council were at stated festivals under the Norman kings; but after the civil wars in the reign of Stephen they were summoned at irregular periods. The inferior or privy council, which, as well as the great council, is indifferently termed *curia regis* in early writers, was composed of members named by the king, and constantly attended on his person; and this inferior body usurped, during the decadence of the great council, and before the full establishment of parliament, many of the legislative functions of the former: but by Magna Charta all aids and scutages were to be assessed by the great council; which thus, in principle at least, possessed a control over the extraordinary revenues of the crown. Any meeting of the great council, or of a portion of it, went by the ordinary name of a "parliament," or colloquy.

But of the constituent parts of this assembly, and the changes which took place in it, no writers give a satisfactory account. All we know is, that it was supposed to consist of all the tenants in chief of the crown; but, by the charter of King John, the archbishops, bishops, abbots, earls, and greater barons, were to be summoned personally; the other tenants in chief by the sheriffs and bailiffs. From this distinction is supposed to have arisen the institution of the peerage as a separate body from the lesser nobility, which so peculiarly distinguishes the constitution of England from those of all other feudal monarchies.

From these mixed assemblies to a representative body the change proceeded by steps, which it is impossible wholly to trace. The first vestiges, perhaps, of representation, appear in the 15th year of King John, when, for a particular purpose, writs were issued to the sheriffs, commanding them to return four knights for each county, "ad loquendum cum rege de negotio regni," at Oxford. But the better known and more distinct evidence of the beginning of the system is found in the Earl of Leicester's parliament after the battle of Lewes, in 48 Hen. 3., when four knights for every county (except nine) were summoned to attend with the barons, probably as representatives of the inferior nobility or lesser barons; and in the following years were issued the earliest writs of summons to parliament. These were to archbishops, bishops, and abbots; to certain earls and barons of the party of the Earl of Leicester; and to the sheriffs of counties and boroughs, to return two knights and burgesses, besides four from each of the Cinque Ports. And although no subsequent writs directed to the sheriffs for the purpose of county elections are in existence earlier than 18 Edw. I., nor of borough elections earlier than the 23d of the same reign, yet it is at least highly probable that the example set by the rebellious Earl of Leicester was ever after substantially followed, and that the representatives of counties and towns were occasionally summoned to parliament; as well for the purpose of assessing tallage and other aids demanded, as for that of giving their counsel respecting other affairs of the government. Edw. I. usually held four parliaments in a year; nor does it appear that these were legislative assemblies: they were rather supreme courts of justice, chiefly attended by the ordinary or privy councillors of the king; while the legislative assembly, certainly composed, after the 23d of this reign, of lords spiritual and temporal and representatives of the commons, was summoned to meet the king occasionally during one of these parliaments.

The constitutional law of the country, whatever it may have been in practice, was first declared by the statute 15 Edw. 2., which annulled the award against the king's favourites, the Despencers. In this act the legislative authority was declared to reside in the king, with the assent of the prelates, earls, barons, and commons, as-

sembled in parliament; and from that time the real existence of that body, and of the form of government which has ever since subsisted, has been uninterrupted, except only during the period of the Commonwealth.

The division of parliament into two houses took place at a period which it is not possible to ascertain; but it is probable that the three orders met in separate conventions for the purpose of assessing taxation, and that the representatives of the commons were at no period admitted to sit in the same chamber with the earls and barons after these were expressly summoned by the king. Although the numbers of both houses have varied materially, no fundamental alteration in their constitution took place from this time until the union with Scotland. (See the Report of the Lords' Committee on the Dignity of a Peer; *Hallam's Constitutional History of England.*)

House of Lords.—1. *Temporal Peers.*—The origin of the English peerage is involved in the same obscurity which rests on other parts of our early constitutional history. The greater barons, as before stated, appear under the first Plantagenet kings to have been those who were personally summoned to the council, while inferior tenants in capite were summoned together by a general compellation; but at what period their dignity became strictly hereditary is unknown.

Baronies are either by tenure, by writ, or by patent. The first were the original feudal titles, in which dignity was invariably attached to the possession of land. The greater barons, who sat of right in the great council, are supposed up to the reign of Henry III. to have been those who were in the possession of entire baronies. But from the date of 22 Edw. 1. it appears that the possessors of entire baronies ceased, of right, to be summoned to parliament; and it is therefore generally held that no barony by tenure subsists at the present day, although some recent efforts have been made to establish a title to this peculiar dignity; the latest claim having been made on the barony of Berkeley, by virtue of possession of the castle of that name.

Baronies by writ were created by writ of summons to parliament, which constituted an individual so addressed by name baron of the realm, and, it is supposed, also made that dignity hereditary. The earliest writ of this description was issued 49 Hen. 3.; and two now existing baronies (Despencer and Roos) are considered to have been created by it. In the case of a barony by writ, the dignity is not conferred until the person so summoned has actually sat in parliament. Baronies by writ descend in fee to all the heirs of the body of the person first created. If there be no son, and more daughters than one, the title falls into abeyance until only one daughter, or the sole heir of only one daughter, survives.

Baronies by patent are created by letters patent, under the great seal, conferring the dignity on the donee; in which are inserted words of limitation. These are usually to the heirs male of the body of the donee; and where there are no words of limitation in letters patent, it is held that the dignity will pass in the same course. Otherwise, the limitation is to other classes of heirs, or to specified persons, and their heirs by way of remainder. *See* Remainder.

Viscountcies are always created by letters patent. This is the most modern of English titles of peerage; and was first conferred on John Viscount Beaumont, 18 Hen. 6. The title vice-comes, or vice-earl, had been long employed to denote the sheriff of a county.

Earldoms were introduced into England by the Normans at the Conquest. The dignity of an earl seems to have been originally attached to the possession of a particular tract of land; but in the reign of Edward III. it began to be conferred by charters or letters patent, with an express limitation either to heirs general or heirs male of the body of the grantee. The word earl is of Saxon origin; but answers in dignity to the count (comes), in languages of Latin descent.

Of *Marquisates*, the first was that of Dublin, conferred on Robert de Vere, Earl of Oxford, for life, by Richard II. The term marquis is derived from the Latin marchio, signifying a military officer, governor of the mark or frontier. This dignity has been always conferred by letters patent.

Dukedoms are the highest titles of the English peerage. The first was created 2 Edw. 3., when Edward the Black Prince was made Duke of Cornwall. It has been a question whether the duchies of Cornwall and Lancaster were not duchies by tenure; but every other dukedom is a mere personal honour, and conferred by charter or letters patent. The term duke is derived from the Latin dux, *leader of an army;* answering to the German herzog, which has the same signification.

All peerages are forfeited by attainder for high treason; and attainder is consequent either on judgment or on outlawry, upon an indictment for that offence. Nothing but a reversal of such act of attainder by parliament can restore an attainted person, or his posterity, to the lost dignity. But where a peerage is vested in a person in tail male, with remainder over to another in tail male, if the first be attainted the peerage is forfeited as to him and his issue male; but, failing such issue male, the dignity becomes vested in the remainder-man, or his descendant.

Peerages by writ are also forfeited by attainder for felony; but not peerages by charter or letters patent.

By the twenty-second and twenty-third articles of the Union between England and Scotland, sixteen representatives are elected by the Scots peers to serve in every parliament of the United Kingdom. The eldest sons of Scottish peers were rendered, by a decision of the House of Commons shortly after the union, incapable of sitting in parliament. It was held for a long time that a Scottish peer could not sit in the House of Lords if he became a peer of Great Britain; but the point was decided the other way in 1780.

By the Act of Union between Great Britain and Ireland (39 & 40 G. 3. c. 67.), twenty-eight lords temporal are elected for life by the peers of Ireland. Peers of Ireland, who are members of the House of Commons, are not eligible to serve as peers while they continue members of the former house.

2. *Lords Spiritual.*—The right of the two archbishops and twenty-four bishops of England and Wales to sit and vote in parliament as members of the House of Lords, is generally said to belong to them as barons of the realm. It is undoubtedly probable that at the period of the Conquest a change took place in the tenure of the lands which were held by bishops and the high regular clergy; and that the Norman tenure by barony, then introduced for the first time, was made to comprehend both spiritual and temporal possessions, which under the Saxon kings had been regarded in a different light. But it is most probable that the dignitaries of the church were constituent members of the great council of the realm, by the English as well as all other feudal constitutions, independent of their quality as barons (see *Hallam, Middle Ages*, c. viii. part 3.); but that the place which was assigned them in the House of Lords, when the two houses became separate, was in virtue of their baronial character. Under the Plantagenet kings the clergy were summoned to meet by their representatives, as well as the laity, when subsidies were required; and under Edward I. (see *Luders on Parliaments*, chap. iii.) attempts were made to unite them and the laity together in parliament; but they were always resisted by the clergy, and at last they ceased altogether to attend in any capacity, retaintaining their own assemblies. (*See* Convocation.) At the period of the dissolution of monasteries by Henry VIII., the spiritual lords consisted of the then archbishops and bishops, and of twenty-six mitred abbots, and two priors, all of whom were then removed on the dissolution of their houses. The present spiritual lords have the same rights and privileges in every respect as the temporal, except that it is still a disputed point in constitutional law whether they have a right, on charge of treason and felony, to a trial by the peers; and it is also doubted whether they have judicial power, as peers, in capital cases.

By the Act of Union between Great Britain and Ireland, four lords spiritual from among the archbishops and bishops of that country sit in the House of Lords by rotation of session.

House of Commons.—1. *Persons qualified to serve in it.*—Persons incompetent to sit as members of parliament are, first, those labouring under the incapacities of alienship, attaint, outlawry in criminal proceedings, minority, lunacy, &c.; next, those who are disqualified by the possession of certain offices, or by certain other temporary causes. Clergymen, peers, Scotch peers, Irish peers for places in Ireland, the eldest sons of Scotch peers for places in Scotland, the fifteen judges of England, the Scotch judges and barons of the Scotch exchequer, are ineligible. Where the influence of government is supposed to have a direct control over the party, a disqualification has been created by various statutes. Persons concerned in the management of the revenues, with some few exceptions, are ineligible. So are persons holding new offices under the crown created since 1705, together with other persons mentioned in 6 Anne, c. 7. So pensioners during pleasure or for a term of years, police magistrates, government contractors, and placemen in public offices, specified in 15 G. 2. c. 22. There are also offices connected with the excise and customs which only disqualify the holder from sitting and voting, but not from being elected. Persons returned on a double return are not competent to sit until the return is decided by a committee.

The acceptance of any office of profit from the crown by a member vacates his seat, by 6 Anne, c. 7. And there are two places of no profit, the acceptance of which is considered to vacate a seat; viz. the stewardship of the Chiltern Hundreds, and the stewardship of the manor of East Hendred. Officers of the army and navy receiving new commissions are excepted from this statute: so are those who accept a foreign employment, as ambassadors.

A member becoming a bankrupt is incapable of sitting and voting for a year, unless within that time the commission is superseded, or the creditors paid; if this be not done within the year, the seat of the member is vacated.

Whether a resolution of the house can render a person ineligible, may still be considered an undecided question.

II. *Electoral Franchise.* — Since the Acts of Union with Scotland and Ireland, and the changes introduced by the Reform Act, the House of Commons consists of 658 members — 500 English and Welsh; 53 Scotch; 105 Irish — divided as follows:

		English and Welsh.	Scotch.		Irish.
Counties		159	30		64
Boroughs		337	23		39
Universities —	Oxford	2		Dublin	2
	Cambridge	2			
		500	53		105

All persons are competent to vote in the election of members of parliament, except infants, women, aliens (unless made denizens by letters patent or naturalized by act of parliament), persons convicted of felony and certain other infamous crimes, peers; Irish peers, unless themselves members of the House of Commons; and persons holding various employments under government not freehold offices. There are also some temporary disqualifications, arising out of employment in particular characters at elections, and the receipt of public alms. They must, however, possess a certain qualification, which (except in the universities, in which the right of voting belongs to all such as have attained certain academical degrees) is one of property.

1. In English and Welsh counties, the right of voting belongs to all such as possess a freehold estate in lands, tenements, or hereditaments, of the value of 40*s.* per annum above reprises; or who are seised of lands or tenements in copyhold, or any other non-freehold tenure for life, or for a larger estate of the value of 10*l.* per annum; or entitled as lessee or assignee to lands or tenements for the unexpired residue of a term of not less than sixty years of the same value, or of a term of not less than twenty years of the value of 50*l.* per annum; and occupiers of lands and tenements at a *bonâ fide* rent of 50*l.* or more per annum. But freehold tenements for life, if under the value of 10*l.* per annum, do not confer a vote, unless the party is in the actual occupation of them, or unless they have come to him by devise, marriage, &c., and not by gift or sale. And in the case of freeholds and copyholds, possession for six months before the last day of July in the year in which the voter is registered is a necessary condition; in that of leaseholds, &c., twelve months.

2. The qualifications of voters in cities and boroughs, in England, were, under the law as it stood before the Reform Act, extremely various, and depending more on the local law of every place than on the general custom of the country. The principal franchises were,—1. In respect of property; thus freeholders to the amount of 40*s.* voted in many towns and cities which were counties of themselves; leaseholders, copyholders, &c., in other places; and burgage tenants. The franchise of burgage tenure, which existed in some towns, depended on the possession of certain ancient tenements, which conferred a right to vote. 2. In respect of corporate privileges. Freemen or burgesses, and in London liverymen (*see* CORPORATION), enjoyed by virtue of their privilege a right of voting in corporate towns. 3. In respect of inhabitancy. Voters in this respect were of four sorts: inhabitants paying scot and lot; inhabitants householders, housekeepers, pot-wallers (*i. e.* pot-boilers), legally settled; inhabitants householders resiant; inhabitants generally. In many towns, several of these qualifications were recognized at the same time as conferring a right to vote.

The alterations introduced into the system of borough qualifications by the English Reform Act were twofold. In the first place, a new franchise is created which is everywhere the same. Every capable person who occupies within the limits of a borough any house or building falling within the specifications of the act, which is either separately or jointly with land held within the same borough as owner, or of the same landlord, of the clear yearly value of 10*l.*, is entitled to vote; provided he has occupied such premises for twelve months previous to the last day of July in the year in which he is registered; and provided he has been rated, and paid all rates for the relief of the poor due up to the 6th of April next preceding, and also all assessed taxes. In the next place, former franchises are modified as follows: — Freemen, and in cities being counties of themselves freeholders and burgage tenants, are to retain their qualification. But no one can claim to be registered as a burgess or freeman who was admitted since the 1st of March, 1831, except he derive his title through birth or servitude; or for a freehold or burgage tenement for an estate acquired since that day. All other borough franchises are abolished, saving their rights to individuals possessed of them at the passing of the Reform Act.

Finally, the act requires that every person, in order to be registered as a voter for a city or borough, must have resided for six calendar months next previously to the last day of July in that year within such city or borough, or within seven miles of it. And it is also provided, that no tenement situate within a borough, and capable of conferring a qualification on its occupier to vote within the borough, shall give a vote for the county.

Several boroughs in Wales, as well as in Scotland, are *contributary;* several towns being joined in one for the purpose of returning members to parliament.

The system of registration of voters, in England and Wales, was framed by the Reform Act. *In counties,* the register is formed by the overseers of the poor in every parish or township making the list by inserting all persons who have delivered to them, before the 20th of July in each year, a claim to vote in respect of property situate within their district. The lists thus drawn up by the overseers, according to a form specified in the act, are delivered to the high constable, and by him to the clerk of the peace for the county. The overseers are empowered to object to any person on their list whom they conceive not entitled to vote. They are also to receive written notices of objection by third parties, who are themselves voters or claimants, duly delivered to them, and to mark the names of all parties so objected to on the list. The lists thus formed are revised by the barrister or barristers appointed for that purpose. These officers are nominated by the senior judge of assize travelling the summer circuit within his district; and by the chief justice of the King's Bench in the metropolitan county and boroughs. Their courts, for the purpose of revising the lists and deciding on claims and objections, must be held between the 15th September and 25th October in every year. The lists revised by them form the register for the county, which is the authentic list of voters until the next registration. Any person having his name and qualification once inserted in the register is not bound to make a claim another year.

In cities and boroughs the course is somewhat different. On or before the last day of July in every year the overseers are to make out an alphabetical list of persons entitled to vote under this act; and another of persons entitled to vote in respect of ancient rights (except freemen, the list of whom is to be made by the town clerk, and in London by the clerks of the several companies). Any person whose name has been omitted in either of these lists is to give notice of a claim, in writing, to the overseer or town clerk. Objections are to be made, in boroughs, only by parties whose names are inserted in the list. The lists are revised by the barristers in the same manner as those for the counties, and delivered to the returning officer.

3. In Scotland, the right of voting in counties is declared by the Scotch Reform Act, 2 & 3 W. 4. c. 65., to be in the owners of ancient rights (termed superiorities) not acquired since 1831: in such persons as have been owners for six months previous to the last day of July of "any lands, feu duties, or other heritable subjects," of the annual value of 10*l.* after deductions. Where two or more parties are interested in any subject to which a right of voting is for the first time attached by the act, as life-renter and as fiar, the right shall be in the former. The right is also extended to tenants for life, or on lease of fifty-seven years or more, at 10*l.* per annum; tenants on lease of nineteen years or more, or occupants at 50*l.* per annum; and tenants who have paid for their interest a price of 300*l.*

4. In Scottish boroughs, the right of voting is in occupiers of houses, &c. (as in the English Reform Act) of the yearly value of 10*l.* Claims by qualified persons to vote for counties are to be lodged with the schoolmaster, and he is to make out the lists of claimants and objections. Claims for votes in boroughs are given in to the town clerk, and the lists made out by him. The sheriff holds courts to decide on questions relative to the registration: his powers and duties are analogous to those of the revising barrister in England.

5. In Ireland, the right of voting in counties is in freeholders at 10*l.* per annum (by the act 10 G. 4. c. 8., which abolished the old 40*s.* qualification); and by 2 & 3 W. 4. c. 88., in leaseholders for sixty years at 10*l.* per annum, for fourteen years at 20*l.*; and in copyholders at 10*l.* per annum.

6. In counties of cities and counties of towns in Ireland, the franchise is in 10*l.* freeholders, 20*l.* leaseholders, 10*l.* householders, and in the 40*s.* freeholders entitled under 4 G. 4. c. 55.; but not in any persons acquiring such freeholds since 1831, except by descent, marriage, &c.; and in 10*l.* occupiers who have occupied for six months: in all other boroughs, in 10*l.* occupiers (the franchise being the same as in England, with the exception that the words "or other building" are omitted) who have occupied for six months. The existing rights of freemen, &c. are saved. Registration in Ireland takes

place at a special session before the assistant barrister or chairman of each county; parties desirous to be put on the register, whether for counties or boroughs, having previously given notice to the clerk of the peace, his deputy, or the high constable. Persons declared by the assistant barrister to be entitled verify their title by affidavit, which is filed of record. An appeal is given to the judges of assize. A certificate of registry is given to each registered voter. Freeholders at 50*l.* per annum may be registered at assizes, or before a judge in Dublin.

III. *Mode of Election.* — 1. In England and Wales, when the sheriff receives the writ commanding him to return a knight or knight of the shire, or division of the shire, he makes proclamation, within two days after receiving the writ, at the place where the election is to be holden; that is, the principal polling place. Counties and divisions are subdivided into convenient districts, with a polling place in each. On the day fixed, after the Bribery Act has been read, the candidates are proposed; and the election proceeds. In boroughs, the sheriff (or other officer to whom the writ is directed) sends his precept to the returning officer, who acts in the same manner as the sheriff in the county; and boroughs are similarly divided into polling districts.

When a candidate is proposed, he may be called on by any other candidate, or any two of the electors, to swear to his qualification. The qualification required by 9 Anne, c. 5., is, for a knight of the shire 600*l.* per annum in lands and tenements, freehold or copyhold, for his own life, or a greater estate; for burgesses, 300*l.* per annum of similar property. Eldest sons of peers, or of persons qualified to sit as knights of the shire, are themselves qualified. Members for the universities are not required to possess any qualification.

It is still questionable whether the returning officer can refuse to return a candidate who refuses to take the qualification oath before the poll. After the election, and before he takes his seat, each member must deliver to the clerk of the house a paper signed by himself containing a description of his estate of qualification, and is sworn to its value at the same time at which he takes the other oaths. His qualification may then be questioned in a petition against his election.

When more candidates are proposed than the number to be returned, the election is decided by the sheriff's declaring the majority on view (by calling on them to hold up their hands). But a poll may be demanded by a candidate or elector, either before or after such declaration by the sheriff.

The poll must commence on the day on which it is demanded, or on the day after. By the Reform Act (s. 58.) three questions only can be asked of any person offering to vote as to his right, — whether he is the same person whose name appears on the register, whether he has already voted, whether he has the same qualification for which his name was inserted on the register; and he may be required to take the oath specified in the act as to his person and qualification. Besides this, the oaths of allegiance, and supremacy, and abjuration, may be put to an elector at the request of any candidate, unless the elector be a Roman Catholic, in which case he may be required to take the oath specified in 10 G. 4. c. 7.: all the foregoing oaths are to be taken before commissioners. The bribery oath may also be administered at the poll by the returning officer. There are also certain local oaths, required by act of parliament to be taken at the election for particular boroughs.

By the Reform Act the poll was limited, in England and Wales, to two days' duration, both in counties and boroughs. And now, by a recent enactment, the poll is declared, in counties, the day next but one after its close; in boroughs, the day after its close. By 5 & 6 W. 4. c. 1. the duration of the poll in boroughs was further limited to a single day. The return is made, in counties, by tacking the names of the persons chosen to the writ; in boroughs, by tacking them to the precepts and returning them to the sheriff, who then tacks them to the writ, and forwards the whole together to the clerk of the crown in chancery. Where the votes are equal, it is the practice to make double returns.

2. In Scotland, the sheriff fixes the day for a county election at not less than ten or more than sixteen days after the writ is received: the counties are divided into polling districts, not exceeding fifteen in number; and the poll lasts two days. In boroughs similar regulations are adopted to those in England; but the sheriff, or his substitute, superintends the poll, which may last three days. The sheriff is the returning officer.

3. In Ireland, the sheriff proclaims the time and place of a county election five days after receiving the writ; and from ten to sixteen days after such proclamation the election is held. In boroughs, the sheriff of a county of a city or town, the mayor, sovereign, or other returning officer, holds the election, not later than eight days after receipt of the precept from the sheriff. The poll shall commence on the day on which it is demanded, and continue five days, but may be closed on any day on which not more than twenty persons have polled.

IV. *Election Committees.* — In the first parliament of James I. a committee of privileges and returns was appointed, to which the trial of every petition against an election was referred which was not heard before the House of Commons. A similar committee was appointed at the commencement of every session, until the present practice of trying such petitions before select committees began. This practice is founded on a variety of statutes, beginning with 10 G. 3. c. 16., commonly called the Grenville Act, consolidated by 9 G. 4. c. 22.

There are six sorts of petitions referred to a select committee: — 1. Complaining of undue election. 2. Of undue return. 3. That no return has been made to the writ in due time, &c. 4. That the return is not according to the requisition of the writ; or complaining of special matters contained in it (as double returns or special returns). 5. To oppose the right of election, or of appointing returning officers, determined by a select committee, and repeated to the house. 6. To defend such right. The four first may be subscribed by any candidate or person claiming a right to vote; the two last by all persons. A petition to be admitted as a party to defend such return, or oppose the prayer of such petition, is addressed to the house, and not referred to a committee. An election petition is presented to the house by a member within a certain time limited by the house. No proceedings will be had on petitions complaining of an undue election or return, &c., unless the subscriber, within fourteen days after its presentation, or farther time limited by the house, enter into certain recognizances for the payment of costs and compliance with other conditions.

When such a petition is presented, a day and hour are appointed by the house for taking it into consideration. At that time, under the Grenville Act, if 100 members were present, the parties and agents attending, thirty-three were selected by ballot; which number, on each party striking off one alternately, was reduced to eleven. If more than one petition is to be taken into consideration on the same day, successive lists of thirty-three were formed, two, three, or more, according to the number of members present in the house. Voters, petitioners, members against whom petitions are presented, and those whose return has not been brought in, were disqualified from serving, and their names, if drawn, were set aside. If no party appeared to oppose the petition, the clerk of the house and the petitioner reduced the list to eleven. This system was considerably altered by the provisions of 2 & 3 Vict. c. 38., an act introduced by Sir Robert Peel. Under it a general committee of elections is appointed by the speaker at the beginning of every session. This general committee chooses six members and a chairman to form a select committee to try an election petition, out of the whole list of members, divided and corrected in the manner therein specified..

The same nicety, it is said, is not required in election petitions, as to their form, as in pleadings at law; but it is now decided, by a series of precedents, that it is necessary that the matter intended to be proved should be sufficiently set forth in the allegations of the petition; and that, on the hearing of the petition, it will not be competent to the party to go into evidence in proof of facts not distinctly alleged therein. But there is considerable variety in the decisions as to what is sufficiency of allegation. An election petition, when once presented, can only be withdrawn by permission of the house: to which jurisdiction in this respect is still left by the Grenville Act. The house will therefore require to be satisfied that there is no fraud or concert in the withdrawal. Supplemental election petitions may be presented, on the discovery of new matter after the presentation of the first petition.

In petitions of the first four classes, parties (if the election is defended) are required to send in to the clerk of the House of Commons lists of the votes to which they intend to object.

Select committees sit every day; but with power to adjourn for twenty-four hours on their own authority, and for a longer period on leave obtained from the house on motion. Members may only absent themselves by leave, or on excuse to be allowed by the house: if any are absent otherwise, the committee cannot sit. Committees are not dissolved by prorogation of parliament, but adjourned to the next time of meeting.

In the first four classes of petitions, the committee have to try the merits of the election; and to determine, by their votes, whether the petitioners, or the sitting members, or either of them, were duly returned; or whether the election is void, and a new writ ought to issue. The fifth class raises the question as to the right of election, or of nominating returning officers, &c. The determination of the committee is in each case final and conclusive; and is embodied in its report to the house at the conclusion of its sittings. A committee has also the power, if it pleases, of making a special report, instead of

deciding generally on the merits; in which case the house makes such order on the report as may seem proper. An examination into the bad votes given on each side is termed a scrutiny; and the effect of it is, that if on balancing the number of good votes retained after such examination the petitioner has the majority, it is reported that he ought to have been returned. Where an incapacitated person has been elected, the principle of parliamentary law is, that if his disqualification was sufficiently known to the electors at the time they returned him, their votes are considered as lost; and it is reported that the next on the poll ought to have been returned. If the fact of his disqualification was not known, the election is simply void. It appears, however, not to be absolutely decided whether the incapacity which renders the votes thrown away must be an inherent or contingent incapacity; as, for example, where it was *publicly known* that a candidate was disqualified by reason of having been guilty of acts of bribery with reference to the election. In this case it has been argued that the election is not void, but that the votes given for the person so disqualified are thrown away. In other cases, bribery, treating, undue interference, &c., have the effect of avoiding elections; and the report is, that a new writ ought to issue.

Finally, an election committee has the power of declaring either the petition, or the opposition to it, "frivolous and vexatious" in its report; the effect of which is to fix the party against whom such declaration is made with the payment of costs. These costs are ascertained by application to the speaker, who directs two persons to tax them, and then grants a certificate; on production of which in a superior court judgment may be entered up for the amount.

V. *Mode of Assembling Parliament.* — Parliament can only be convened by the authority of the king; and, by 6 W. & M. c. 2., must be held at least once every three years; but, in point of fact, as the Mutiny Act, Land Tax, and Malt Act are only passed for a single year, the sittings of parliament are of necessity annual. The same order by the king in council which commands the lord chancellor to cause the great seal to be affixed to a proclamation for dissolving parliament, is accompanied with a warrant to issue writs for a new one. Writs for the return of members of the House of Commons are directed to the sheriffs of counties, with certain exceptions: viz. the returning officers of places counties in themselves, the Bishop of Durham, the Chancellor of the Duchy of Lancaster, the Chamberlain of the County Palatine of Chester, the Constable of Dover, and the Warden of the Cinque Ports. On a vacancy during the sitting of parliament, the writ issues under warrant of the speaker by the authority of the house itself.

VI. *Meeting of Parliament. Preliminary Proceedings.*— The new parliament meets on the return day of the writ, unless prorogued by writ of prorogation; but when it is intended that it should meet for the actual despatch of business on the day to which it is prorogued, notice to that effect is given by proclamation forty days before; and the parliament begins only on the day to which it is prorogued. The acts of meeting and passing a statute constitute together a session. Upon the assembling of parliament the king meets it in person, or by representation, and explains in his speech the reasons of convening it. In modern times, the speech is not delivered until the commons have chosen a speaker, which they receive a command from the king to do.

The first occasion on which this important officer is expressly named occurs in the parliament 51 Edw. 3. His duties are, — to act entirely as the servant of the house which appoints him. He takes the chair, which he cannot do unless forty members are present; maintains order, by naming (if necessary) members who are disorderly; explains and informs on questions of order or practice, if he is referred to. He can neither speak nor vote unless in case of equality of votes; or in committees of the whole house, where, as soon as the chair is taken, he is reduced to the footing of an ordinary member.

On the first day of the meeting of every new parliament certain oaths are administered to the members by the Lord Steward of the King's Household: these are the oaths of allegiance, supremacy, and abjuration; but, by the Roman Catholic Relief Act, members professing that religion take, instead of these oaths, a declaration substituted for them. By 33 G. 2. c. 20. they are also required to make oath that they are qualified, and deliver in their qualification at the table. But, previous to being sworn, every person returned is to all intents and purposes a member of the house, except as to the right of voting only. Before the king's speech is taken into consideration, it is usual to read a bill as a matter of form. The king's speech being then reported to the house, an address of thanks, as moved or as amended, is returned. The usual committees are then appointed: of these the committee of privilege is the only one of which the duties are at present of a practical kind.

The method of proceeding in making laws is, for the most part, similar in the two houses; but different in public and private bills.

VII. *Method of Proceeding on Bills in general.*—Statutes are divided into public and private; and the distinction, in a parliamentary sense, is merely derived from the payment of fees, which are due on private and not on public acts. Constitutionally, public acts are, in general, such as relate to the kingdom at large; private acts, to individuals and classes. Many acts, however, which immediately concern classes only are within the category of public acts; as, for instance, acts concerning all spiritual persons, or all lords of manors. Judicially the distinction between the classes is, that the courts of justice are officially bound to notice public acts; but private acts must be formally shown or pleaded. This rule, however, admits of certain technical exceptions.

All private bills affecting the peerage must begin with the lords; all bills which, directly or indirectly, impose a charge on the people must begin with the commons. This class, therefore, includes all bills under which tolls may be levied for private benefit; such as bills for making roads, canals, railways, bridges, inclosure bills, and bills containing clauses inflicting pecuniary penalties for offences against private property, &c.

All other private bills may begin with either house indifferently; but, in practice, one large class of private enactments, — viz. estate bills, which enlarge or alter the power of individuals in disposing of their property; divorce bills; bills to enable parties, under statutable restrictions, to alienate, &c., — begin in the lords; that house, from its judicial character, being best fitted for the discussion of similar subjects. On the other hand, bills concerning the parliamentary rights, &c. of particular places, usually commence, by custom, in the commons. There is one instance of a bill which begins with neither house, but with the crown; viz. a bill for a general pardon. Bills are always read in each house, after leave has been given to bring them in, three times before they are passed (with the exception of bills of grace, such as for a general pardon, which are passed on the first reading). General petitions against a bill are usually ordered to lie on the table until the second reading; on which occasion counsel are heard against a bill, whenever leave is given for their introduction. The second reading affords the legitimate period for discussion on the principle of the bill; and the bill is then (as indeed it is, on principle, in every stage) open to the proposal of amendments. If a bill be rejected, either on the first or second reading, it cannot be again proposed that session. After the second reading, the bill is committed; *i. e.* referred either to a select committee, or, if the bill be of importance, to a committee of the whole house. Such a committee requires, in the commons, the presence only of forty members; in the lords, of all members in attendance. In committee the bill is debated clause by clause, with the advantage that members are not restricted, as in a debate of the house, to speaking once. The proper province of the committee is to consider the bill in its details. When the bill has gone through the committee, the chairman reports it to the house, with such amendments as the committee may have made. The house can then agree or disagree with the amendments of the committee. (*See* Amendment.) The bill is then engrossed, and afterwards read a third time. In the commons, it is usual to read a bill which originates with the lords the third time on the same day on which it is reported. A new clause added to a bill on the third reading is termed a rider. A bill thrice read, and passed, admits of no farther alteration, except for clerical errors. A bill sent from the commons to the lords is usually read the first time in the latter house on the day on which it is brought; and, when it has passed through the different stages, is sent back to the commons, with the amendments, if any have been made, with which the commons then agree or disagree; the same process, substantially, being followed, vice versâ, where the bill originates with the lords. The amendments returned with a bill from one house to another are taken into separate consideration; and the amendments, if agreed to, are always considered as proceeding from that house in which the bill first originated. If one house cannot agree to the amendments proposed by the other, a conference is usually held between members deputed by each house, who can only make use of the instructions delivered by the house in their arguments, the conference being desired by that house which disagrees with the amendments in question. If the house which amends is not satisfied at the first conference with the reasons alleged for its disagreement by the other, it desires another conference; if this too is unsuccessful, what is termed a free conference may be demanded, in which the managers of the conference are not under the same restrictions as to instructions, but may urge their own arguments. If one or more free conferences fail of producing unanimity, the bill is dropped. It is necessary to observe, that in bills of supply (which originate in the commons) the lords cannot make any except verbal amendments; they must either admit

or reject altogether. When a bill has passed both houses, it is deposited in the House of Lords, to wait for the royal assent (except in the case of a bill of supply, which is presented by the speaker to the throne). The royal assent is given either in person, or by letter patent under the great seal, notified by commission. The bill then becomes a statute, is transcribed into a roll by the clerk of the parliament, delivered into chancery, and by usage, although not necessarily, printed at the king's press.

VIII. *Method of Proceeding on Private Bills.*—Petitions for private bills must be presented in the commons within fourteen days after the first Friday in the session ; and, on being presented by a member, are referred to a committee, which is then named, consisting of five members selected by the committee clerk. The committee on the petition ascertains whether or not the standing orders applicable to the case have been complied with ; in which case they make their report accordingly to the house: leave is then given to bring in a bill ; unless, as in some cases, it is expedient first to re-commit the report. The bill having been read a first time, after an interval which is varied in practice according to the nature of its subject, the house proceeds to the second reading ; on which occasion objections to the *principle* of the bill are usually made, specific objections to its provisions being more properly reserved to a later stage. A member may, individually, oppose a private bill in any stage, or he may present a petition against it. On the bill being read a second time, it is referred to a committee, which is formed in the same manner as the first committee on the petition. In the committee on the bill all the blanks left on its first introduction are filled up, and amendments introduced ; and, if unopposed, the bill is reported. Opposition to a private bill, in a committee of the House of Commons, is conducted as follows : — The petition against the bill, having been referred to the committee, is read there ; if the parties supporting it appear, the promoters of the bill first state their case, and produce and sum up their evidence in support of its preamble ; the opponents next state their case, produce and sum up their evidence against it ; the promoters then reply, and the committee vote. If the committee resolve that the preamble is proved, the clauses are read, and the opponents are at liberty to make objections to each successively ; the promoters not being called upon otherwise to offer evidence in support of them. The presence of five members of the committee is necessary to any proceeding. A committee cannot dissolve itself, and consequently its existence continues until it has reported to the house ; although by adjourning indefinitely, or by voting the chairman out of the chair, they might in effect entirely release themselves from the duty imposed on them ; but the house, in similar cases, has exercised the power of ordering the committee to proceed forthwith.

When the report is brought up and read, as in the case of other bills, it is ordered to lie on the table. After seven days, the amendments having been read and agreed to, it is ordered to be engrossed ; after which it is competent to any member to move the third reading of it. Additional clauses added at this time are termed riders. When passed, the member who presented the petition, with seven others, takes it to the House of Lords, and delivers it to the lord chancellor. If the lords make amendments, the concurrence of the commons to these amendments is moved by the same member. Should the lords' amendments not be agreed to (a rare occurrence in private bills), a conference is held by a deputation from both houses; and, should the disagreement continue, the bill is finally withdrawn, or rather dropped.

IX. *Standing Orders of the House of Commons.*—These are a series of regulations, adopted by way of resolutions of the house at various periods, from 1685 to the present time, relating partly to the internal order, &c. of the house, partly to certain preliminaries and forms required on the introduction of particular bills, both public and private, and to the promulgation of statutes. The most numerous of these relate to private bills, and specify the mode of signing and presenting, the time for delivering notices and their necessary contents, the formalities to be required respecting instruments, and a variety of other particulars. When a resolution is made which is intended to be permanent, it is usual to add the form, " Ordered that the said resolutions be standing orders of the house." Standing orders on private bills are sometimes (but only on special application) dispensed with by the house, or farther time, &c. given for complying with them.

X. *Rules of Business in the two Houses.*—In the Commons, a house for the transaction of business consists of forty members, by an order of the year 1640 ; and, if a less number be present, the speaker will not take the chair. This rule extends to committees of the whole house. The speaker of the House of Commons cannot speak in the house ; the speaker of the House of Lords may. A call of the House of Commons is an expedient to secure attendance for an important occasion : when it is made, members absent without leave may be ordered to be taken into custody. No member can be present on the debate of a bill or other business concerning himself. The order " for the sergeant-at-arms to take into custody strangers that are in the gallery of the house " is repeated every year, the first instance having been in 1705 ; so that the House of Commons is supposed to sit with closed doors, although the order is partly permitted to be infringed. When the speaker's mace lies upon the table of the House of Commons, it is a house ; when under, a committee ; when out of the house, no business can be done ; when in the hands of the sergeant at the bar, no motion can be made.

With regard to the manner of speaking and voting in the commons, motions are made, and petitions presented, by a member *in his place;* the readings of bills, &c. are moved *at the table.* The member who moves a motion puts it in writing, and delivers it to the speaker, who, when it has been seconded, puts it to the house ; it cannot then be withdrawn except by leave of the house. The *motion to adjourn* is put in order to supersede a motion of which the house is already in possession. The motion *for reading the order of the day* has equally the effect of superseding the existing question. The motion *for the previous question* has been commonly but mistakenly attributed to Sir Harry Vane, as its inventor. It can take place only in a house, and not in a committee ; in which latter the equivalent motion is, *that the chairman do now leave the chair.* The speaker names the member whom he first perceives to rise in order to speak ; but the house is not bound by the speaker's decision. It is understood to be the rule, that a member may speak even after the question put, if the affirmative voice only has been given, and the negative not yet given. The effect of the speaker's " naming a member," on the occasion of disorder in the house, is that such member, after being heard, if he pleases, is directed to withdraw, and the house then considers what penalty to inflict. In the commons, votes are given by *ay* and *no ;* if a division is demanded, the speaker (by a resolution of 1603) appoints two tellers on each side to count. Strangers are directed to withdraw, and the doors closed before the question is put. On a division one party leaves the body of the house, the other remains ; and the general rule is, that the side which is for the *innovation* goes out ; thus, on the question on a bill, the *affirmative* voices go out : but this rule is governed in its application by various special usages. On a division in a committee of the whole house, the ayes go on one side, and the noes on the other. The speaker has the casting vote in a house, the chairman in a committee.

In the House of Lords.—The general rules of proceeding in the House of Lords vary little in material points from those adopted by the commons. The speaker can debate as well as vote. Votes are given seriatim, the youngest baron voting first. The privilege of the lords to vote by proxy is only by licence from the king. Proxies from spiritual lords are only to spiritual ; proxies from temporal only to temporal. No lord can hold more than two proxies. The lord chancellor is ex officio speaker of the House of Lords ; and as he is able to speak and vote, he has no casting vote : the rule, therefore, in case of equality of voices always is, that the presumption is in favour of the negative side.

With regard to messages between the two houses, those from the commons to the lords are sent by one member, but will not be received unless eight at least attend in all. Messages from lords to commons are sent by two masters in chancery ; or, on special occasions, by two judges. Messages from the king are of various sorts : those to the commons, to desire any proceeding on their part, are usually written in the king's own hand ; those which are sent when a member of the house is put under arrest on account of the public service are verbal, and delivered by a minister of the department of service concerned. (See *Hatsell's Precedents in Parliament.*)

XI. *Jurisdiction of Parliament as a Court of Justice.*—i. For the trial of a peer, indicted for treason or felony, or for misprision of either, the lords spiritual and temporal sit as the court of the lord high steward of England, an office which is in general created *pro hâc vice* by a commission under the great seal. But, if the trial should occur during the sitting of parliament, it is said to be before the same court " of our lord the king in parliament ;" in which case the high steward is only, as it were, pro tempore speaker of the house, and has a vote with the other peers ; whereas, in his own courts, held in the recess of parliament, he is judge of the court, and, like any other judge, sole arbiter on the question of law.

ii. The House of Lords has also a twofold jurisdiction ; 1. in criminal cases, 2. in civil cases. — 1. The first is for the trial of high crimes and misdemeanors by the method of parliamentary impeachment by the House of Commons. (*See* Impeachment.) The proceeding on a bill of attainder, or of pains and penalties, is, in fact, a legislative act, and not a judicial one. (*See* Attainder, Pains and Penalties, Bill of.) 2. The jurisdiction of the House of Lords, in civil cases, is divided by Lord Hale

into their jurisdiction in the first instance, and in the second instance as a court of appeal; but the former, which consisted in special powers of interference, occasionally exercised for particular purposes, is now obsolete. In the last instance, the House of Lords is the supreme court of judicature in the kingdom. Appeal lies to it, by writ of error, from the court of King's Bench, and from the subordinate court of appeal of the Exchequer Chamber; and appeal from the High Court of Chancery also, not only in order to obtain the reversal of a decree, but also on any interlocutory matter. On writs of error, the House of Lords pronounces the judgment; on appeals, it gives directions to the court below to rectify its own decree.

XII. *Privilege of Parliament*, in the ordinary sense of the words, denotes the privileges of individual members of either house, enjoyed by virtue of their seats. These privileges are partly limited by known precedent, or by statute; but they are to a great extent customary, and the houses themselves constitute the only tribunals before which the inquiry whether their privileges have been violated or not can be instituted.

The first privilege is freedom of speech in debates: this claim is sanctioned by the statute 2 W. & M. 2., which declares the liberties of the people. This privilege does not extend to the publication of what is spoken: if a member publish his speech without the authority of the house, he is liable to the common legal tribunals for its contents. An exception to the privilege also is to be found in the jurisdiction of the house itself; which has the power of committing, expelling, or fining (the latter not exercised since the reign of Elizabeth) a member for a libel or contempt against the dignity of the house.

The next privilege, of freedom from arrest in civil suits, is probably as old as parliament itself. Privilege of parliament was formerly supposed to exempt peers and members of the House of Commons from civil actions as well as arrests; but this was finally abolished by 10 G. 3. This is the privilege of peerage, not of parliament; consequently it extends to Scotch and Irish peers. The exemption does not extend to criminal cases, or breaches of the peace; or to attachments in case of contempt by the superior court. And, by a peculiar process enacted by 10 G. 3., a member of parliament may be made a bankrupt. Unless the commission is superseded within twelve months from its being issued, he vacates his seat. The liberation of parties improperly arrested is effected either by the authority of the houses themselves, or, when parliament is not sitting, or (in the case of peers) when it is dissolved, by writ of privilege, or on motion in the superior courts. The duration of the privilege, in the case of members of the lower house, is not exactly defined. It is the general opinion that it extends forty days after every prorogation, and forty days before the next appointed meeting. Members of parliament are not liable to be called on to serve as jurors during sitting or adjournment.

The old privilege of franking was fixed, by 4 G. 3. c. 24., to continue during the same period which is mentioned as that of freedom from arrest. By 35 G. 3. c. 53. it was restrained to letters within an ounce in weight, and the number to ten sent and fifteen received. It is now altogether abolished.

The general or "ancient and just" privileges of the houses are, as has been said, undefined. "The law of parliament," says Hallam, "as determined by regular custom, is incorporated into our constitution; but not so as to warrant an indefinite uncontrollable assumption of power in any case, least of all in judicial proceedings, where the form and essence of justice are inseparable from each other."

Besides the general privilege of parliament, we may here briefly notice the privileges claimed by the two houses, or by members of them, with respect to the conduct of their legislative proceedings.

Two privileges peculiar to the House of Lords are, 1. That possessed by every peer of giving his vote by proxy. (See antè, *Rules of Business in the two Houses*.) 2. That which he possesses of entering on the journals of the house his dissent from a vote of the house, together with his reasons for it, which is styled his protest. The first protests, with reasons annexed, are said by Lord Clarendon to have been made in 1641.

Of the peculiar privileges of the House of Commons, the most important is that of originating all money bills; and this, in principle, is a very ancient part of the constitution. But it was not before 1690 that it was fully established that the lords could not alter, any more than originate, any rate or tax granted by the commons. This privilege is now understood under the following limitations: — In bills of aid and supply, the lords can neither originate them nor make any alterations beyond verbal amendments. In bills which impose pecuniary burdens as a collateral object, — such, for example, as bills for turnpike roads and canals, or for the management of the poor, — the lords may make amendments, but not such as affect the quantity, disposition, or collection of the rate. No amendments may be made by the lords which appear likely, in their consequences, to bring a charge on the people; nor can they insert or alter pecuniary penalties and forfeitures in a bill.

By a resolution bearing date 1667, and now strictly adhered to, any proposition for taxing the subject must be first examined by a committee of the whole house, and their opinion reported. The effect of this rule is, that subjects on which frequent speaking by the same member, and other departures from regular proceedings are desirable, are discussed in a meeting unfettered by some of the special rules of the house.

When a bill of supply has received the concurrence of the lords, it is returned to the commons, and by them presented to the throne.

XIII. *Adjournment.*—An adjournment is a continuance of the session from one day to another. This is done by each house for itself, either from day to day, or over a recess, as at Christmas and Easter. In neither house can the speaker adjourn unless upon motion of the house. The king can signify his desire of an adjournment; but has no further power.

XIV. *Prorogation of Parliament.* — A prorogation is the continuance of parliament from one session to another: and is made by the royal authority, either expressed by the lord chancellor in the king's presence, or by writ under the great seal, or by commission. In the proclamation for prorogation, if it is intended that parliament, when next it meets, shall proceed to the despatch of business, notice is given of that purpose; and such notice bears date usually forty days at least before the day appointed for meeting; but, in time of rebellion or danger of invasion, the king is empowered to call together parliament with fourteen days' notice only.

XV. *Dissolution of Parliament* is effected either, 1. By the king's will, which is the exercise of one of his highest prerogatives: this is usually done by proclamation after parliament has been prorogued. 2. By the demise of the crown; but, by 7 & 8 W. 3., the existing parliament continues six months after that event; assembles immediately, if under prorogation or adjournment; and if there be no parliament at the time, the members of the last parliament are empowered to reassemble themselves. 3. By efflux of time; viz. at the end of every seventh year, if not sooner dissolved by the Septennial Act, 1 G. 1. s. 2. c. 38. The seven years are counted from the day on which parliament was appointed to meet in the writ of summons.

Pa'rliament, or Parlement. (Fr. parlement.) The title of certain high courts of justice under the old French monarchy. The French parliament, like those of England and Naples, was in its origin a convocation of the great vassals of the crown, who treated of judicial as well as political matters in their assemblies. Saint Louis was the king who first introduced into this body counsellors of inferior rank, chiefly ecclesiastics, as legal assistants; and the earliest registers of the proceedings of the parliament, which afterwards became fixed at Paris, are of the date of 1254. The important step of rendering that court permanent, and fixing its seat in the capital city, is generally attributed to Philip the Fair (1304): from that time the great barons gradually discontinued their attendance, and the lawyers occupied the higher places and more important functions of the court. The twelve peers of France, however, remained constant members of the parliament, after the other great vassals had, by disuse, ceased to be considered as members of it (although they, likewise, in process of time, ceased to take part in its judicial business). The parliament of Paris thenceforward remained the chief tribunal of the country until the revolution, with the exception of the short period of its suppression by Louis XV. in 1771; but as the great fiefs of the French monarchy were successively united to the crown, the supreme feudal court of each was invested with the title and attributes of a parliament. These were fixed at Toulouse, Grenoble, Bordeaux, Dijon, Besançon, Rouen, Aix, Pau, Rennes, Metz, Douay, Nancy. The most remarkable prerogative exercised by the parliaments is one of which the origin has not been satisfactorily accounted for; that of registering the edicts of the sovereign, and thereby giving them the force of law. M. Meyer (*Institutions Judiciaires*, liv. iv. ch. 9.) supposes that it arose from the character of the parliament, as the court of the feudal lord of each province: thus, the edict of the king of France was referred to the parliament of Bordeaux, to examine whether it interfered with the special rights and duties of the same sovereign as duke of Guienne, &c. It appears, however, to have been the received doctrine, by the end of the 14th century, that this formality of registration was essential to the validity of an edict in every province. Hence the important part which the parliaments, and especially that of Paris, so often enacted in French history, in modifying the otherwise absolute power of the monarchs. (*See* Bed of Justice.) It was usual for the parliament of Paris, and undoubtedly legal, although not customary, for the other parliaments, to convey remonstrances to the king on the

subject of his edicts. But Louis XIV. ordained that these remonstrances should always be presented after they had testified their obedience by registering them. The parliaments had also a power of a legislative character, that of pronouncing *arrêts de reglement*, by which they gave authoritative decisions on legal questions, not only binding on present but in future cases. The counsellors of parliament were, by a law of Louis XI., immoveable except in case of legal forfeiture; but the place of counsellors and presidents early became purchaseable, and afterwards transmissible by hereditary descent. Hence, in part, the powerful esprit de corps which distinguished those bodies. As a high court of appeal, the parliament of Paris was divided into five chambers; one termed the great chamber, three *des enquêtes*, one *des requêtes*. Besides these, the *chambre de la tournelle*, in which criminal cases were tried, was a fluctuating court, in which members of all the regular chambers sat in turn.

PA'RLOUR (Fr. parler, *to speak*), signified originally the little room in which in former times the nuns and monks used to give interviews to their visitors; or in which the novices used to converse together at the hours of recreation.

PARME'NIANISTS. In Ecclesiastical History, a name given to the Donatists (see that article), from Parmenianus, Bishop of Carthage, one of their chief leaders, and an antagonist of Augustine.

PARNA'SSUS. In Mythology, a celebrated mountain in ancient Greece, sacred to Apollo and the Muses, and, from the numerous objects of classical interest of which it formed the theatre, considered "holy" by the Greeks. On its side stood the city of Delphi, near which flowed the Castalian spring, the grand source of ancient inspiration; and from this circumstance, in metaphorical language, the word Parnassus has come to signify poetry itself. A good collection of the Italian poets, printed at Milan, bears the title *Il Parnasso Italiano*.

PA'RODY. (Gr. παρα, and ῳδη, *a song*.) A species of composition in which the form and expressions of portions or passages of grave or serious writings are closely imitated in similar passages of a ridiculous character. Parody is a species of burlesque (*see* BURLESQUE); but the imitation is more close and exact than in ordinary burlesque composition. Antiquity has left us no complete works of this species, although some fragments are preserved by Athenæus and other writers. The *Batrachomyomachia*, the authorship of which is attributed to Homer, though a very ingenious specimen of the burlesque, is not, in the modern sense of the word, a parody. The French critics do not seem to draw an adequate distinction between the nature of a parody and a *travestie*.

PAR'O'L. (Fr. parole.) In Law, word of mouth. Thus, a parol agreement is contrasted with one in writing, parol with written evidence, &c. For the legal principles bearing on this distinction in different cases, see AGREEMENT, CONTRACT, EVIDENCE.

PARO'LE. In Military matters, the allowing of prisoners to enjoy certain indulgences, on their giving their word of honour (*parole d'honneur*) that they will not serve during the continuance of the war against the country by which they are liberated, or upon their pledging their word to abide by such other conditions as may be stipulated.

PA'RONOMA'SIA. (Gr. παρα, and ὀνομα, *a name*.) In Rhetoric, a figure by which the same word is used in different senses, or words similar in sound are set in opposition to each other; so as to give a kind of antithetical force to the expression.

PARONY'CHIA. (Gr. παρα, and ονυξ, *the nail*.) A whitlow.

PARO'NYMOUS. (Gr. ονομα, *name*.) In Grammar, words of similar derivation, or principal words with their derivation: e. g. *equus*, *eques*, *equito*; *man*, *manhood*, *mankind*.

PARO'TID GLAND. (Gr. παρα, and ους, *the ear*.) A large gland situated under the ear, between the maxillary process of the temple bone and the angle of the lower jaw. It secretes saliva, which is carried into the mouth by the *Stenonian duct*.

PAROTI'TIS. Inflammation of the parotid gland. The *mumps*.

PA'ROXYSM. (Gr. παρα, and οξυς, *sharp*.) In Medicine, the periodical exacerbation of a disease.

PARR. This name is applied in most parts of England and Scotland to the young of the salmon (*Salmo salar*, Linn.) up to near the end of their second year, when they lose their dark lateral bars by the superaddition of a silvery pigment, and congregate together for their seaward migration. From the circumstance of the milt and roe being developed at this immature period, a precocious condition by no means uncommon in the cold-blooded tribes, the parr has been regarded by some ichthyologists as a distinct species, and was described as such by Willughby and Ray, under the name of *Salmo salmulus*. *See* SALMON.

PA'RREL. In Naval language, the collar of greased rope, or trucks, by which the yard is confined to the mast while it slides up and down it.

PA'RRICIDE (Lat. pater, *a father*, and cædo, *I kill*), implies, properly, the murder or murderer of a father. But the term is also extended to the murder of any near relative, as a husband, wife, mother, &c.; and even to that of distinguished or sacred persons, as a king, archbishop, &c. The Athenians had no law against parricides, from an opinion that human atrocity could never reach to the guilt of parricide. This was also originally the case at Rome; but at a later period parricide was punished by the Roman law with greater severity than any other kind of homicide. The delinquent, after being scourged, was sewed up in a leathern sack, with a live dog, a cock, a viper, and an ape, and so cast into the Tiber. The English laws treat this crime only as simple murder; but in some of the German states the criminal convicted of parricide is put to death with exquisite torture, the penalty being that such persons shall be beaten to death with iron clubs, beginning with the feet, and gradually ascending to the head.

PA'RSEE. (Pers. parsi.) The name given by English writers to the Persian refugees, driven from their country by the persecutions of the Mussulmans, who now inhabit various parts of India. Their principal emigration to Baroach, Surat, and the neighbouring coast, is supposed to have taken place about the end of the 8th century. The sacred fire, the emblem of their religion (*see* GUEBRES), called *behrem*, is believed by them to have been brought by the first emigrants from Persia, and, after many changes of place, is now preserved at Odisari and Nausari, near Surat, and at Bombay. In this latter city, under the protection of the British government, they have grown into a colony of considerable numbers and of great opulence. They have become particularly distinguished in the art of shipbuilding, and the dockyard of Bombay is now almost exclusively in their hands. Their character is variously estimated by different observers; but all agree in attributing to them industry and economy, and attachment to their religion, and to those of the higher class strong sentiments of honour and honesty. Their number is said to equal 700,000; and at Bombay, according to late calculations, at least 20,000.

PA'RSING. The art of resolving a sentence into its grammatical elements or parts.

PA'RSON. (Lat. persona ecclesiæ.) In Law, one that has full possession of all the rights of a parochial church. His title is derived from the Latin persona, because in his person the church itself which he occupies is represented; and he is a corporation sole. A parson, or rector, has the freehold of the parsonage house, the glebe, the tithes, and other dues, during his life. Four requisites are necessary to constitute a parson: holy orders, presentation, institution, and induction. See these terms. In common language, parson is a vulgar term for a clergyman of any kind.

PART. (Lat. pars.) In Music, a single piece of the score or partition, being one set of the successions of sounds which constitute the harmony.

PARTE'RRE. (Fr.) A system of beds of different shapes and sizes in which flowers are cultivated, connected together, with intervening spaces of gravel or turf for walking on. The form of the beds may vary according to the taste of the designer; but their breadth should never be greater than will admit of the spectator who wishes to gather flowers, or the gardener who is to cultivate them, reaching the middle. Where the object is chiefly to produce a display of flowers, the beds should be of simple shapes, with few acute angles, as these can never be completely covered with plants; but where the object is to display a curious figure, to be seen from a point considerably above the level of the parterre, the beds may be formed of arabesque shapes, or like the figures used in embroidery and lace-work. Figures of this description are generally planted with dwarf box, kept low by clipping, with only here and there a flowering plant, or a small shrub, placed in the broadest parts of the beds or scroll-work. Parterres of this description were in use during the time of the Romans, as appears by the description of Pliny's own garden by himself, in which the letters composing his name were planted of box, kept regularly clipt, a practice not uncommon in Rome and its neighbourhood at the present day. Embroidered parterres, however, were brought to the highest degree of perfection in the time of Louis XIV., when the arabesque style of ornament was introduced into every thing. The flowers and flowering shrubs in culture in those days were comparatively few; and hence the leading features of the parterre were beds of turf, always an object of luxury, and requiring to be kept up at considerable expense of watering in the climate of France, and scroll-work of box. This description of parterre was imitated in England; but smooth green turf not being here an object of luxury, beds of flowers became more frequently substituted in its stead; and as the number of foreign flowers introduced increased, the number of turf

beds and scroll-work diminished, till, at the present time, the latter is rarely to be met with. In this manner has gradually arisen the modern English flower garden, which consists of small beds, more or less orbiculate, and scattered over a surface of smooth turf, so as to combine into groups, which are planted with flowers, or low flowering shrubs; sometimes in masses of only one kind in a bed, and at other times of several kinds mixed together.

Parterre. In French, the pit of a theatre.

PA'RTHENON. (Παρθενών.) The magnificent temple of Minerva in the Acropolis of Athens, so called in honour of the virginity of that goddess (from παρθένος, *a virgin*). It was a peripteral octostyle of the Doric order, with 17 columns on the sides, each 6 ft. 2 in. in diameter at the base, and 34 ft. in height, elevated on three steps. Its height, from the base of the pediments, was 65 ft., and the dimensions of the area 233 ft. by 102. The eastern pediment was adorned with two groups of statues, one of which represented the birth of Minerva, the other the contest of Minerva with Neptune for the government of Athens. On the metopes was sculptured the battle of the Centaurs with the Lapithæ; and the frieze contained a representation of the Panathenaic festivals. Ictinus, Callicrates, and Carpion were the architects of this temple; Phidias was the artist; and its entire cost has been estimated at 1½ million sterling. Of this building 8 columns of the eastern front and several of the lateral colonnades are still standing. Of the frontispiece, which represented the contest of Neptune and Minerva, nothing remains but the head of a sea horse and the figures of two women without heads. The combat of the Centaurs and the Lapithæ is in better preservation; but of the numerous statues with which this temple was enriched, that of Adrian alone remains. The Parthenon, however, dilapidated as it is, still retains an air of inexpressible grandeur and sublimity; and it forms at once the highest point in Athens, and the centre of the Acropolis. It is hardly necessary to inform the reader that the chief portion of the sculpture of the Parthenon is now placed in the British Museum, where it forms, with some additions, the collection of the Elgin Marbles. *See* Elgin Marbles.

PARTI'CIPANTS. A semi-religious order of knighthood, founded by Pope Sextus V., in 1586, in honour of Our Lady of Loretto. The members of this order were allowed to marry. The order was soon extinguished; and the title of Knights of Loretto is now conferred on some civil servants of the pope.

PA'RTICIPLES. (Lat. participium.) A part of speech which *partakes of* the properties both of a verb and an adjective. It may be described either as a verb without affirmation, or as an adjective with the addition of the notion of time. *See* Grammar.

PA'RTICLE. (Lat. particula, *little part.*) In Grammar, a general term to express the subordinate or secondary parts of speech, — the adverb, the preposition, and the conjunction. But it is more in accordance with grammatical precision to apply this term to those minor words to be met with in all languages, which serve apparently to give clearness and precision to a sentence, but respecting whose exact use Grammarians are not agreed. To this class belong the Gr. γε, αρα, τοι, δη, &c.; the Germ. ia, wohl, &c.; and the English *now*, *then*, *truly*, &c. The term *particle* is also applied by grammarians to those words or enclitics (as they are called, from Gr. εν and κλινω, *I lean*) which cannot be used separately, but must form part of the preceding word, as in *virumque*.

Particle, in Physics, denotes the minutest parts into which a body can be mechanically divided. It is in general used synonymously with molecule, corpuscle, atom; but sometimes these terms are distinguished.

PARTI'CULARISTS. In Theology, those among the Reformed who have held the doctrine of God's particular decrees of salvation and reprobation. As a party name, it seems to date from the Synod of Dort. That branch of the Baptists attached to high Calvinistic opinions is still called the church of the *Particular* Baptists.

PARTI'DAS, LAS SIETE. (Span. *the seven parts.*) A celebrated ancient Spanish code of laws, drawn up in the reign of Alphonso X. of Castile (about 1260), so called from the number of principal parts into which it is divided. This famous collection did not acquire the obligatory virtue of a code until 1338, when sanctioned by Alphonso XI.

PARTI'TION. (Lat. partitio.) In Music, the arrangement of the several parts of a composition on the same page or pages, ranged methodically above and under each other, so that they may be all under the eye of the performer or conductor, and sung or played jointly or separately as the composer intended. It is commonly called a *score*.

Partition. In Architecture, the vertical assemblage of materials which divides one apartment from another. It is usually, however, employed to denote such division when constructed of vertical pieces of timber called *quarters*.

Partition. In Politics, the division of the states of a sovereign or prince after his decease among his heirs, as was the custom in some of the princely families in the ancient German empire; or among other powers, such as that of the states of the king of Spain, which was in contemplation (against all justice) between William III., Louis XIV., and the Dutch, by the treaties of 1698 and 1699, when Charles II., the reigning monarch, was without near heirs. But the most celebrated partitions in history, to which the name has become almost exclusively attached, were those of Poland, by Russia, Prussia, and Austria. The first of these took place in 1772, when various provinces were wrested from the republic in pretended satisfaction of ancient claims, and the old and vicious constitution guaranteed by the three powers. The second was submitted to by Stanislas in 1793, when Russia obtained the remainder of Lithuania, and Prussia Dantzic, Thorn, and an extensive district. This partition was followed by the insurrection under Kosciusko, which brought about the third and last partition in 1795, when the remnant of the country was dismembered. It was organized in 1807, altered in 1815; but the conditions under which Poland was then annexed to Russia, as a separate kingdom, were entirely set aside after the Polish insurrection of 1830, and it is now substantially and in fact a province of Russia. These partitions overturned the ancient balance of power in Europe, and prepared the way for the violent changes which followed the French revolution. (See Koch, *Revolutions de l'Europe;* Rulhieres, *Histoire de l'Anarchie de Pologne;* Ferrand, *Histoire des Trois Démembremens de Pologne*, 3 vols. Paris, 1820; *Ed. Rev.* vol. xxxvii. p. 462.)

PA'RTNERSHIP. A relation established between two or more persons, by an agreement to combine property or labour in furtherance of a common undertaking, and for the acquisition of a common profit. A community of profit between the parties is the true criterion of a partnership; for one partner may stipulate to be free from loss, and this stipulation would be effectual as between himself and his partners, though he would be liable equally with them to the world at large. A dormant partner, that is, one who in point of fact participates in the profits of a firm, but is not held out as a member of it, will nevertheless be liable for its engagements, because he takes part of that fund which is a security to creditors for payment of their debts. There is no particular form necessary to the constitution of a partnership, nor is it necessary that the contract should be in writing. It may be dissolved at the individual pleasure of any one partner, if no stated period has been fixed for its continuance; and, even if such a period has been fixed, it will be dissolved, in the absence of any proviso to the contrary, by his bankruptcy, attainder, or death, or by marriage, in the case of a female. Courts of equity, also, will put an end to it by decree, on proof of lunacy or gross misconduct. A partnership is by any of the above matters terminated as between the partners themselves; but, to prevent a continuing liability to strangers, public notice of the dissolution is necessary. One partner cannot sue another at law in respect of the partnership account, unless a balance has been struck, the remedy being in equity, which affords a machinery better adapted to the investigation of accounts. As regards the rights of third persons against the partnership, it is a general rule that it will be bound by the engagements of any one partner acting with reference to the joint business, either by his simple contracts on the purchase and sale of goods, or by negotiable instruments circulated on its behalf.

PA'RTNERS OF THE MASTS. The woodwork round the mast at the deck, to strengthen and support the deck against the pressure of the mast. The term is also applied to the similar supports round the capstan and pumps.

PA'RTRIDGE WOOD. A variegated wood imported from Martinique: it is said to be the produce of the *Heisteria coccinea.*

PA'RTY. In Politics, a body of men united under different leaders for promoting by their joint endeavours the national interest, upon some particular principle in which they are all agreed. The origin of party may be traced to that law of the human mind which is founded in our natural desire of sympathy and our disposition to afford it. From the earliest ages down to the present time, the principle of mutual co-operation has been adopted with success in executing favourite designs, and in aiming at the accomplishment of certain ends. Among the ancient Romans, for example, "*idem sentire de republica*" formed a principal ground of friendship and attachment; and the same feeling, modified by different forms of government and other circumstances, is at present in full operation in all the civilized states of Europe and America. The benefits of party may be briefly stated to be, increased energy in pursuit of a common object, regular co-operation, mutual control and regulation, and an advantageous division of labour. But though party or combination may in this manner be productive of good results, like every other principle and feeling in our nature, it is liable to be abused and there can be no

doubt that it is frequently attended with such evil consequences as greatly to countervail its admitted benefits. It involves a frequent sacrifice of individual notions of what is just and proper, and tempts bodies of men to act in a way that would often be deemed discreditable in individuals. Perhaps the worst effect of party is its tendency to generate narrow, false, and illiberal prejudices, by teaching the adherents of one party to regard those that belong to an opposing party as unworthy of confidence; and in making them oppose good measures because they happen to be proposed by a different party, and support bad measures because they are proposed or supported by their own party. A thorough-going party adherent is in fact a political slave; a person who allows others on all occasions to think for him; who, as far as politics is concerned, has no principle or rule of action, save that of slavish adherence and blind obedience to the dictation of the leader of his party. (The uses and abuses of Party are discussed with great ability in vol. xxx. of the *Edin. Review*). The different parties, both of England and other countries, will be found under their respective heads.

PARTY. In Heraldry — as party per pale, fess, &c.; terms used to signify the division of a shield by a line running in the direction of either of these ordinaries.

PARTY WALL. In Architecture, the wall separating two buildings belonging to different owners or occupiers. The regulations relative to the thickness of party walls in the metropolis have been the subject of several statutes, beginning with one passed 19 Car. 2. and ending with the 14 Geo. 3., better known by the name of the Building Act. This last governs the thickness of all party and external walls to be built after 24th day of June, 1774.

PARULIS. (Gr. παρα, and ουλον, *the gum*.) A gum-boil.

PA'RUS. (Lat. parus, *a titmouse*.) A genus of Conirostral Passerine birds allied to the crows, characterized by having the conical beak straight and rather slender, with few hairs at its base; nostrils round, and covered by reflected bristly feathers; the hind toe is strong, and armed with a long hooked claw. To this genus belong the native birds commonly called tits or titmice, of which the tomtit (*Parus cæruleus*, Ray) is the best known species. The great tit (*Parus major*), the marsh tit (*Parus palustris*), the cole tit (*Parus ater*), and the crested tit (*Parus cristatus*), have the bill longer and more pointed; the last-named species is rare in this country. They are active little birds, continually flitting from spray to spray, and suspending themselves in all kinds of attitudes, rending apart the seeds on which they feed, devouring insects, and not even sparing small birds when they happen to find them sick and are able to destroy them. They store up provisions of grain, build their nests in the holes of trees, and produce more eggs than is usual among the Passerine birds.

PA'SCHAL CYCLE. The name given to the cycle which serves to ascertain when Easter occurs. It is formed by multiplying by each other the cycle of the sun, which consists of 28, and the cycle of the moon, which consists of 19 years. *See* PASSOVER.

PA'SCHAL FLOWER. The *Anemone pulsatilla*; so called from its flowering about Easter.

PASI'GRAPHY. In Literature. (Gr. πας, *universal*, and γραφω, *I write*.) The imaginary universal language, to be spoken and written by all nations, the invention of which has exercised the ingenuity of so many learned men, has been denoted by this word. Leibnitz seems to have been one of the first who conceived this to be possible. Many writers in Germany (where the name was invented) have followed him in the endeavour to devise schemes for this fanciful object. In England, Bishop Wilkins, in the reign of Charles II., invented a scheme for a universal language, grammar, and character.

PASQUINA'DE. (Ital. pasquinata.) A satirical writing directed against one or more individuals. A mutilated ancient statue of a gladiator dug up at Rome about 300 years ago, which now lies in the court of the Capitol, was popularly termed, by the Romans, "Pasquino," from the name, it is said, of a barber of eccentric and well-known character, opposite to whose house it was originally set up. This statue, and another, called by the populace Marforio, which was situated near it, were used for the purpose of bearing satirical placards, often reflecting on the court and church of Rome, which were affixed to them at night, not unfrequently in the form of a dialogue between the two statues. So annoying did Pasquin often become to the government, that on one occasion a serious design was entertained of throwing him into the river; but the ministers of the reigning pontiff are said to have dissuaded him from it, representing that if this were done "the frogs in the Tiber would croak louder than ever Pasquin had spoken." He has, however, lost his public spirit, and rarely or never ventures to attack the powers that be. But his statue is still the occasional receptacle of jocose comments on private matters. M. Matthews (*Diary of an Invalid*) mentions an instance which occurred during his stay at Rome. A man of the name of Cæsar (common among the townsfolk there) had married a girl of the name of Roma. Pasquin was placarded with "Cave, Cæsar, ne tua Roma respublica fiat." The man replied by Marforio, "Cæsar imperat." To which the retort was "Ergo coronabitur." Hence Pasquinata and Pasquilles became, in Italy, conventional words to signify writings of that description, and have been naturalized in other languages. In French and German they have been used in the legal vocabulary for libel.

PASS, in a military sense, signifies a strait or narrow defile which shuts up the entrance into a country.

PASSAGE. (Lat. passus, *a step*.) In Architecture, the part of a building allotted for giving access to the different apartments.

PASSAGE. In Music, a portion of an air or tune consisting of one, two, or three measures.

PASSAGE, BIRDS OF. *See* MIGRATION.

PASSANT. In Heraldry, a term used to describe a beast when represented in a walking position. Passant guardant, walking with the full face turned towards the spectator.

PASSEPARTOU'T. In Engraving, a plate or wood block, whose centre part is entirely cut out round the outer part, whereof a border or ornamental design is engraved, serving as a frame to what may be placed in the centre.

PA'SSERINES, *Passeres*, or *Passerinæ*. (Lat. passer, *a sparrow*.) The name given by Linnæus and Cuvier to the typical order of birds including those which neither manifest the violence of the birds of prey, nor have the fixed regimen of the terrestrial birds, but which feed on insects, fruit, or grain, according to the slenderness or strength of their beak; some with sharp and toothed mandibles pursue and feed on small birds. All the Passerines have short and slender legs, with three toes before and one behind; the two external toes being united by a very short membrane. They form the most extensive and varied order of birds, and are the least readily recognizable by distinctive characters common to the whole group. Their feet, being more especially adapted to the delicate labours of nidification, have neither the webbed structure of those of the *swimmers*, nor the robust strength and destructive talons which characterize the feet of the *bird of rapine*, nor yet the extended toes which enable the *wader* to walk safely over marshy soils, and tread lightly on the floating leaves of aquatic plants; but the toes are slender, flexible, and moderately elongated, with long, pointed, and slightly curved claws.

The Passerines in general have the females smaller and less brilliant in their plumage than the males; they always live in pairs, build in trees, and display the greatest art in the construction of their nests. The young are excluded in a blind and naked state, and wholly depend for subsistence, during a certain period, on parental care. The brain arrives in this order at its greatest proportional size; the organ of voice here attains its utmost complexity; and all the characteristics of the bird, as power of flight, melody of voice, and beauty of plumage, are enjoyed in the highest perfection by one or other of the groups of this extensive and varied order.

The beak of the Passerines varies in form according to the nature of their food, which may be small or young birds, carrion, insects, fruit, seeds, vegetable, juices, or of a mixed kind. The modifications of the rostrum have therefore afforded convenient characters for the tribes or subdivisions of the order: these are termed, 1. *Dentirostres*; 2. *Conirostres*; 3. *Tenuirostres*; 4. *Fissirostres*. See those words.

PASSIFLORA'CEÆ. (Passiflora, or Flos passionis, one of the genera.) A natural order of twining plants with very showy flowers, furnished with numerous rays of brilliant colours between the corolla and the stamens. They chiefly inhabit the hotter parts of the world, and bear a fruit not unlike that of the gourd, to which natural order they are related. Independently of the beauty of their flowers, some yield fruits, eaten under the name of granadilla and water lemon; and others have a hard black wood, not unlike ebony.

PASSING NOTES. In Music, graces wherein two notes are connected by smaller intervening notes.

PA'SSION. (Lat. patior, *I suffer*.) The sufferings of our Lord, which he is described as having endured between the Last Supper and the moment of his death. Passion-week is that in the course of which these sufferings took place; namely, that immediately preceding Easter. (See as to its solemn ceremonial in the Romish church, this article in the *Encyclopædia* of Ersch and Gruber.) It was variously called *Hebdomada luctuosa*, *inofficiosa*, *pœnosa*, *indulgentiæ*, *nigra*, *sancta*, *ultima*.

PA'SSIONS. The name popularly given to the different emotions of the mind, as love, anger, &c. Various ingenious speculations have been instituted to ascertain whether the precise situation of the impetus of the pas-

sions be in the spiritual or material part of man. Some philosophers, and among these Des Cartes, consider them wholly seated in the corporeal system. Mallebranche regards them as those agitations of the soul which proceed from uncommon influence and motion in the blood and animal spirits. "Though the passions," says Burton, in his *Anatomy of Melancholy*, "dwell between the confines of sense and reason, yet they rather follow sense than reason, because they are drowned in corporeal organs of sense. They are commonly reduced into two inclinations, *irascible* and *concupiscible*. The Thomists subdivide them into eleven, six in the *coveting* and five in the *invading*. Aristotle reduceth all to pleasure and pain, Plato to love and hatred, Vives to good and bad. If good, it is present, and then we absolutely joy and love; or to come, and then we desire and hope for it: if evil, we absolutely hate it; if present, it is sorrow; if to come, fear. . . . All other passions are subordinate unto these four, or six, as some will, — love, joy, desire, hatred, sorrow, fear. The rest, as anger, envy, emulation, pride, jealousie, anxiety, miserie, shame, discontent, despair, ambition, avarice, &c., are reducible unto the first" (*i.e.* the *irascible*). With several writers it has been a question whether the passions be each a distinct innate disposition, or merely modifications of those dispositions which are common to all mankind. The theories and conjectures of philosophers upon this subject are almost boundless; but to pursue them would be of little advantage, even if our limits permitted, and we shall merely refer the reader for ample particulars to the works of Hume, Reid, Hartley, Locke, Lord Kames, &c. (See also *Maass's Versuch Uber die Leidenschaften*, 2 thle. Halle, 1805.)

Passions. In Painting and Sculpture, the representation in the countenance and other parts of the violent emotions of the mind, produced by anger, fear, grief, &c. The expression of the passions is a language without which the painter can never hope for success: it is in this that he has the means of appealing to the sympathy of the spectator. The close observation of nature under similar circumstances is the only mode by which his aim can be accomplished.

PA'SSOVER, or PASCHA. A festival among the Jews, which derives its English name from God's *passing over* the houses of the Israelites, and sparing their first born, when those of the Egyptians were put to death. The name of passover or paschal lamb was likewise given to the *lamb* slain in memory of that deliverance. The festival lasted seven days, beginning on the evening of the 14th of the month Nisan, and commenced with killing the lamb. The regulations appointed for this festival are detailed in Exod. xii.

That the passover had a typical reference to our Saviour has been the universal belief of the Christian world in all ages, and is mainly grounded on passages in St. John and St. Paul. (John, xix. 36.; 1 Cor. v. 7.) Christ is said to be our passover; his blood being shed to protect mankind from the divine justice, as the blood of the paschal lamb, which was sprinkled upon the door-posts of the Israelites' houses, preserved them from the visitation of the angel of the Lord.

PA'SSPORT. A warrant of protection and authority to travel, granted to persons moving from place to place by the competent officer. The word appears to be derived from the maritime usage of some continental countries, of giving similar authorities from the admiral of a naval station to vessels leaving harbours within his jurisdiction. As passports are not required in our own country, the only species known to British travellers is that of foreign passports, which, for an Englishman travelling on the continent of Europe, are usually made out by the resident minister or consul of the country he intends first to visit, in London, or at one of the ports. They are also granted by the Foreign Office on payment of fees, which now (1841) amount in all to 2*l.* 7*s.* They are subject to visa or inspection by the proper authorities at the place where the traveller disembarks, and also at other places which he may reach, according to the police regulations of each particular country, and on passing the frontiers of states. Austria is, we believe, the only European state which at this time requires absolutely the visa of an ambassador or minister of her own for travellers entering her domains by land. In France, and in many continental countries, home passports are necessary for the native traveller. According to the letter of the French law (since 1796), a Frenchman cannot pass the limits of the canton in which he is domiciled without a passport; but in practice it is not required within the extent of the department. Legally speaking, the strict formalities of an internal passport, in France, require the direction of a journey to be specified, and its exact execution attested by the visas and signatures of the police authorities at every place mentioned in it; and these laws are, from their severity, so incapable of complete execution, that it is a common saying, that no man but a rogue is ever entirely en règle with respect to his passport, suspicious characters being usually the most particular in their attention to formalities, for fear of detention. A Frenchman travelling without properly authenticated passport is liable to arrest, and detention for a period not exceeding a month. The fees fixed in France are two francs for a passport to travel at home, and ten to go abroad.

PASTE. (Fr. pâte.) In Gem Sculpture, a preparation of glass, calcined crystal, lead, and other ingredients, for imitating gems. This art was well known to the ancients, and, after being long lost, was restored, at the end of the fifteenth century, by a Milanese painter.

Some modern artists have succeeded in obtaining a composition possessing a hard, fine, and brilliant lustre or appearance; but *pastes*, or mock diamonds, as they are called, depend most for brilliancy on the art displayed in setting the foil or tinsel behind them. Several recipes have been given by M. Fontanien; but the most useful, and that generally employed for the production of artificial diamonds, is the following: — Take of litharge 20 parts, of silex 12, of nitre 4, of borax 4, and of white arsenic 2 parts. These ingredients are to be well mixed together in a crucible and melted; the fused metal is thrown into water; and should any of the lead employed be reduced to the metallic state, it becomes separated by this process, and the glass is remelted for use. For the finer kinds rock crystal is used instead of flint or sand, as it occurs in a much purer state; *i.e.* more free from the admixture of metallic oxides, which give to vitreous compounds their different colours. In place of the above, Loysel recommends the following ingredients to form a compound having the same specific gravity as the oriental diamond, and on this account considered superior, as it more nearly approaches the gem with regard to its refractive and dispersive powers; but, like the former, it requires to be kept for some two or three days in a fused state, in order to expel the superabundant alkali and to perfect the refining. A moderate degree of heat fuses it. The following is its composition: — Take of white sand purified by being washed, first in muriatic acid and afterwards in pure water, until all traces of acid are removed, 100 parts; red oxide of lead (minium) 150 parts; calcined potash 30 to 35 parts; calcined borax 10; and oxide of arsenic 1 part. (See the *Polytechnic Journal* for July, 1841.)

The term paste is also applied to the earthy mixture for pottery and porcelain; also to dough, and to the solution of starch or wheat flour, made by first mixing it with a proper portion of cold water, and then adding boiling water under constant stirring, so as to form an even solution. Alum is often added to paste to strengthen it.

PA'STEL. (Lat. pastillus.) In Painting, a crayon formed with any colour and gum water, for painting on paper or parchment. The great defect of this mode of painting is its want of durability. *See* Crayon.

PA'STERN. The part of the horse's foot under the fetlock to the heel.

PASTI'CCIO. (It.) In Painting, a picture painted by a master in a style dissimilar to that in which he generally painted. David Teniers could, for instance, imitate, with surprising exactness, the styles of many of the first masters of Italy and Flanders. The same may be affirmed of Luca Giordano, a Neapolitan artist.

PASTI'L. In Pharmacy, a kind of lozenge. A compound of charcoal with odoriferous substances, which diffuses an agreeable perfume during its slow combustion.

PA'STORAL. *See* Eclogue, Bucolic, Idyl.

PA'STOUREAUX. (Old Fr. *shepherds*.) Insurgent peasants, who took up arms in France during the absence of King Louis IX. on his crusade. They were led by an apostate Cistercian monk, who took the name of "Jacob, Master of Hungary," who seduced them to follow him in various fanatical extravagances. They committed various excesses, from the frontier of Flanders, on which they at first assembled, to Bourges, where their leader was killed in a tumult, and his horde dispersed.

PASTURE. Land under a particular decription of grasses and herbage, which is eaten on the spot by horses, cattle, &c. Hill pasture is a term applied to hilly and mountainous lands, which are kept perpetually under the natural grasses and herbage which spring up on them; while artificial pastures are such as are sown by art on lands which are occasionally subjected to the plough. In all artificial pastures the principal grass is rye grass, and the principal herbage plant the white clover. Perpetual pastures are such as are never subjected to the plough, and never receive any other manure than what is left on them by the pasturing animals; but artificial pastures are occasionally mown, and sometimes receive a top-dressing of dung, or some mixture of dung and earth, lime, &c.

PATAVI'NITY. A term in use among critics to denote a provincial idiom in speech; so named after that of Livy the historian, from his being born at Padavium, a provincial town of the Roman empire. Wherein the alleged defect of Livy's writings consists has never been distinctly pointed out by any critic, ancient or modern.

PATE. In Fortification, a kind of platform encompassed with a parapet, and having nothing to flank it.

PATEE, or PATTEE. (Fr.) In Heraldry, a sort of cross, small at the centre and widening towards the ends, which are very broad.

PATE'LLA. The small, flat, and somewhat heart-shaped bone, which is placed at the fore part of the knee joint, and commonly called the *kneepan*.

PATELLOI'DS, *Patelloidea*. The name of a family of Cyclobranchiate Gastropods, having the limpet (*Patella*) as the type.

PA'TEN. (Lat. patina.) In Ecclesiastical usage, the stand or saucer on which the chalice rests. It was frequently highly ornamented by artists in the 15th and 16th centuries. In the administration of the Eucharist in England, the paten is the vessel on which the bread is placed.

PA'TENT, in Commercal Law, is defined a privilege from the crown granted by letters patent, conveying to the persons specified therein the sole right to make, use, or dispose of some new invention or discovery, for a limited period. This power is said to be inherent in the crown; but was first defined by stat. 21 J. 1. c. 3., which gives the term of fourteen years or under, "so they be not contrary to the law, nor mischievous to the state, by raising prices of commodities at home, or hurt of trade, or generally inconvenient." Ever since the reign of Anne it has been a condition in patents, that the inventor should, by an instrument technically called a "specification," particularly describe and ascertain the nature of his invention; on failure of which the patent becomes void. These letters are obtained on petition to the crown, and are granted on the recommendation of the attorney or solicitor general. An injunction may be obtained, or an action brought, for the infringement of a patent; but it is necessary to show the novelty and utility of the invention, and that it is of something capable of being turned immediately to account in commerce; no patent will be good for a mere philosophical principle neither organized nor capable of being so. It is now held that a new process or method, as well as an article, may be the subject of a patent. A party who believes himself to have discovered an invention, but has not yet been able to reduce it to practice, may enter a *caveat*; that is, an instrument by which notice is desired to be given by any one who may seek a patent for a similar invention. The law of patents has been recently amended by 5 & 6 W. 4. c. 77., and some difficulties under which inventors were placed, particularly as to the strictness of the specification, removed; but the policy of some of the clauses is questioned.

The phrase *letters patent* is also frequently applied to the state documents or ordinances of the German sovereigns: in which sense it is equivalent to the *bulls* of the pope, or the *ukases* of the czar.

PATENT YELLOW. A pigment obtained by fusing a mixture of oxide and chloride of lead.

PA'TERA. (Lat. patere, *to be open.*) In Roman Antiquities, a large open goblet or cup of gold, silver, marble, or earth, &c., used in offering libations to the gods.

PATERA. In Architecture, the representation of a cup, usually in bas relief, and employed to decorate friezes, fasciæ, imposts, &c.

PATERI'NI. One of the names by which the Paulicians, a sect which appeared in Italy in the 11th century, were very commonly known. The origin of the term is obscure, as is also the connection of the sect with the Manicheans of the East. (See *Faber on the Church of the Waldenses and Albigenses.*)

PA'TERNO'STER. The Latin expression for *Our Father*, signifying the Lord's Prayer. *See* ROSARY.

PATER PATRA'TUS. In Roman Classical Antiquities, the chief of the fecials or heralds; specially named for the performance of certain solemn acts, such as declarations of war.

PATHE'TIC. (Gr. παθητικος; from πάσχω, *I suffer.*) In Painting and Sculpture, the expression of the softer or more sorrowful passions. Its tendency is to depress and compose the feelings of the spectator.

PATHETIC NERVES. A pair of small nerves, which influence the expression of the face. They rise in the brain, and supply the trochear muscle of the eye.

PATHOGNOMO'NIC. (Gr. παθος, *a disease*, and γνωμη, *opinion.*) Symptoms which are peculiar to particular diseases, and by which they are recognized, are termed pathognomonic symptoms.

PATHO'LOGY. (Gr. παθος, and λογος, *a discourse.*) Literally, the doctrine of disease. As physiology teaches the nature of the functions of the body in a state of health, so pathology relates to the various derangements of these functions which constitute disease. Its objects, therefore, are to ascertain the various symptoms which characterize the disorders of each organ of the body, and especially the diagnostic and pathognomic symptoms, which afford the means of discrimination between diseases that resemble one another; to determine the causes, both predisposing and exciting, by which diseases are induced; to point out the tendency and probable issue of each disease from the varying appearance of the symptoms; and finally to explain the symptoms of recovery, and the nature and operation of the remedies adapted to the various circumstances and periods of diseases. (*Conversations Lexicon.*)

PA'THOS (Gr. παθος, *suffering*), is applied in literary language to any composition calculated to excite all, but chiefly the tender, emotions of the mind. In France, this term is generally used in a somewhat disparaging sense, being applied to that species of composition which indulges in strained and unnatural declamation.

PA'TINA. (Gr. πατανη, *a dish.*) In Numismatics, the fine rust with which coins become covered by lying in peculiar soils, which, like varnish, is at once preservative and ornamental. It is, says Mr. Pinkerton, a natural varnish, not imitable by any effort of human art; sometimes of delicate blue, like that of a turquoise; sometimes of a bronze brown, equal to that observable in ancient statues of bronze; sometimes of an exquisite green, a little on the azure hue, which last is the most beautiful of all. It is also found of a fine purple, of olive, and of a cream colour, or pale yellow, which last is exquisite. The Neapolitan patina is of a light green; and, when free from excrescence or blemish, is very beautiful. Sometimes the purple patina gleams through an upper coat of another colour, with as fine effect as a variegated silk or gem. In a few instances a rust of deeper green is found, and it is sometimes spotted with the red or bronze shade, which gives it the appearance of the East Indian stone called bloodstone. These rusts are all, when the real product of time, as hard as the metal itself, and preserve it much better than any artificial varnish could have done; concealing, at the same time, not the most minute particle of the impression of the coin. Gold admits no rust but iron-mould, when lying in a soil impregnated with iron. Silver takes many kinds, but chiefly green and red, which yield to vinegar; for in this metal the rust is prejudicial.

PA'TOIS. (Supposed to be derived from Lat. pater, *a father.*) A word in general use in most European countries, signifying the dialect peculiar to the lower classes.

PATRES CONSCRIPTI. *See* CONSCRIPT FATHERS.

PA'TRIARCH. (A compound of πατηρ, *father*, and αρχω, *I govern.*) The title given by the sacred writers to the earliest heads of families recorded in Scripture, from Adam to Jacob and his sons. This title was assumed also in the early ages of the church by the bishops of the principal cities of the empire, as Rome, Constantinople, Antioch, &c. The name was adopted from the practice of the Jews; who, after the dispersion, subjected themselves to the spiritual superintendence of the patriarchs resident at Tiberias and Babylon. The first mention of a Christian patriarch occurs about 440. They were, for the most part, superior to archbishops or metropolitans, being set over several provinces. This, however, was not always the case. The patriarchs of Ephesus and Cæsarea, for instance, were subject to the bishop of Constantinople, and were only on a par with diocesan prelates. (See *Hooker*, *Eccles. Polity*, 6, 7.; *Mosheim*, vol. i. pp. 179. 349., trans. 1790.)

PATRI'CIANS. (Lat. patres, *fathers.*) The first order or nobility of the Roman people. When the constitution of Rome was monarchical, they elected the king; and after the expulsion of the Tarquins all the great officers of state, as consuls, prætors, &c., were chosen from their body for many generations. Of the patricians, also, the senate was composed; but, in after times, both this and the great magistracies were thrown open to the plebeians. The subdivisions of this order were as follow:—First, they were classed into three tribes, called Ramnenses, Titienses, and Luceres; of which the first contained the original patricians of Romulus, the two latter being probably admitted to their privilege at different subsequent times. Each of these tribes again was divided into ten curies, and each curia again contained ten clans, or gentes. The general assembly of the patrician houses, who constituted the populus, in contradistinction to the plebs, or plebeian citizens, was called *comitia curiata*, because they voted therein by curies; and this, in the earliest times, was the Roman popular assembly, to which plebeians were not admitted.

PA'TRICK, SAINT, ORDER OF. An Irish order of knighthood, instituted by George III. in 1783, composed of the sovereign, a prince of the blood royal, a grand master, and fifteen knights; the lord-lieutenant of Ireland for the time being is grand master.

PATRIPA'SSIANS (Lat. pater, *father*, and passio, *suffering*), are persons who, by overlooking the distinction between the persons of the Trinity, are reduced to allow that the Father himself suffered on the cross. This argument has been advanced against heretics of various denominations, and the title has, in consequence, been applied to many such. It is the Sabellians, however, who considered the Father, Son, and Spirit as three modes or representations of the one God, that are generally opprobriously designated by this term. *See* SABELLIANS. (See also *Mosheim*, vol. i. cent. 4.)

PATRI'STIC. (Lat. pater, *father*.) In Theology, of or belonging to the fathers of the church; as patristic theology, literature, study.

PATRO'LE. (Fr. patrouille.) In Military language, a detachment, ordinarily of from four to eight men, under a corporal, charged to march in a given circuit through the streets of a garrison town, in order to repress disorder. The patroles are drawn from the posts of the city, and set out at an hour fixed by the commandant. They are usually accompanied, in Continental towns, by an officer of police.

PA'TRON. (Lat. patronus; from pater, *father*.) The relation of patron and client, in ancient Rome, has been explained under the head CLIENT. After the extinction of republican sentiments and usages, the term patron was still applied to advocates who defended causes for hire. But the right of patronage, analogous to that which had subsisted under the commonwealth, may be said only to have existed in the relation between masters and freedmen, the latter of whom were placed under various obligations to their former owners. In the usage of the Roman Catholic Church, a *patron* saint is the peculiar protector of each country, community, profession, &c., or of individuals. The prime minister of the pope is termed the cardinal-patron. (As to the Roman patrons, see *Mem. de l'Acad. des Inscr.* vol. xii.)

PA'TRONAGE. In the Church of Scotland, the right of presentation to livings in lay patrons was recognized by the old practice of the church, with the exception of the period from 1690 to 1712; during which lay patronage was abolished, and the right of presentation lodged in the heritors (land owners) and members of the kirk session. In 1712, lay patronage was restored; but still under the control of the parishioners, whose *call* (as it was termed) was necessary to ratify the presentation. But the call gradually became a mere nominal ceremony; and disregard to the expressed wishes of the parishioners in one or two instances was the cause of the great secession from the Scottish kirk. (*See* BURGHERS.) In 1834, by an act of Assembly (*see* VETO ACT), the right of the parishioners was fully revived; it being expressly enacted that the disapproval of a majority should invalidate the presentation. This act of the General Assembly, however, is found by the courts of law not to be efficient. The abolition of patronage is desired by a large portion of the Scottish public; and it is highly probable, unless some legislative arrangement be come to on the subject, that the present disputes in the Scotch church will terminate in a new secession.

PATRONY'MIC. (Gr. πατηρ, and ονομα, *a name*.) A name which designates a person by alluding to some of his ancestors, either immediate or remote; as Pelides, *i.e.* Achilles, the son of Peleus; Æacides, *i.e.* Achilles, the grandson of Æacus. Patronymics were chiefly employed by the classical poets of antiquity.

PA'ULIANISTS. A sect of heretics who embraced the Sabellian doctrines of Paulus of Samosata, a bishop of Antioch in the third century, from whom they derived their name. *See* SABELLIANS, PATRIPASSIANS.

PAULI'CIANS. A sect of heretics, whose history is interwoven with that of the Greek church in the 9th and 10th centuries, who appear to have arisen in considerable numbers in Armenia, and to have adopted the name by which they are distinguished, from Paulus, one of their leaders, in order to avoid the imputation of connection with the Manicheans, with which they were generally charged. Their opinions are to be collected only from the allegations of their enemies, who accused them of holding the doctrine of the two principles, and denying the inspiration of the Old Testament to have proceeded from the Supreme God. At the same time, the charges which were brought against them, alleging their contempt for the worship of the Virgin and of the cross, seem to point them out as in some respects genuine reformers in doctrinal points, and to have led their bigotted enemies to invent other and more scandalous imputations against them, for the sake of more effectually blackening their character. In the East, they underwent a series of persecutions for two centuries: a remnant, however, survived in the country of their birth. A colony of Paulicians was transplanted to Bulgaria and Thrace, from whence, in the 11th century, they spread themselves over the West, where they were known under the names of Cathari, Paterini, &c., and have been supposed to have been connected with the Albigenses of the south of France. (See *Mosheim*, vol. ii.; *Faber on the Churches of the Waldenses and Albigenses*, 1838.)

PAUPER. *See* POOR LAWS.

PAUSE. (Gr. παυω, *I stop*.) In Music, a character denoting silence in a part for a certain time, according to the sort of pause marked.

PAVAN. (Lat. pavo, *a peacock*.) A slow and stately dance formerly practised in England, but now confined to the Spaniards. It derived its name from the peculiarity of the dresses of those who engaged in it, the motion of which produced a fancied resemblance to the peacock's tail.

PA'VEMENT. (Lat. pavimentum.) In Architecture, a causeway or floor paved with stone, brick, or other hard material, for greater convenience of walking. *See* ROADS.

PA'VESE, or PAVOIS. A large shield, used in the warfare of the middle ages to cover assailants advancing to the walls of a fortress.

PAVI'LION. (Fr. pavillon.) In Architecture, a projecting apartment on the flank of a building, usually higher than the rest of it. Summer houses in gardens are sometimes called by this name, but improperly. The term pavilion is also used to signify a military tent.

PA'VO. (Lat. *a pea-fowl*.) The name given by Linnæus to the genus of Gallinaceous birds, of which the splendid Indian peacock (*Pavo indicus*, Linn.) is the type. They are characterized by a crest of peculiar form, and by the tail coverts of the male extending far beyond the quills, and being capable of erection into a broad and gorgeous disk. The shining lax and silky barbs of these feathers, and the eye-like spots which decorate their extremities, are known to every one. The Indian pea-fowl exist wild in the north of India, whence they were introduced into Europe by Alexander the Great. A distinct species of pea-fowl exists in the Isle of Java.

PAW'NBROKER. A species of banker, who advances money at a certain rate of interest upon the security of goods deposited in his hands; having power to sell the goods if the principal sum, and the interest thereon, be not paid within a specified time. The practice of advancing money to the poor, either with or without interest, seems to have been occasionally adopted in ancient times; but the first public establishments of this kind were founded in Italy, under the name of Monti di Pietà, in the 14th and 15th centuries, and were intended to countervail the exorbitant usurious practices of the Jews, who formed at that period the great money-lenders of Europe. From Italy these establishments gradually spread over the Continent, in many parts of which they still exist. (*See* MONT DE PIETE.) For a view of the advantages and disadvantages of pawnbroking, and the law as to pawnbrokers, &c., see the *Commercial Dict.*

PAX. An allegorical divinity among the ancients, worshipped as the goddess of peace. She had a celebrated temple at Rome, which was built by Vespasian, and was consumed by fire in the reign of Commodus. This term is sometimes applied to a small image of Christ, because, in former times, the kiss which the people gave it before leaving church was called the kiss of peace. But the common pax, or osculatorium, was a metallic plate with a crucifix engraved on it. It is now disused. (See Ducange, *Osculatorium*; Milner, in the *Archæologia*, vol. xx. p. 534.)

PA'YMASTER-GENERAL OF THE FORCES. This office was formerly extremely lucrative, from the interest on the large sum of money which remained for a long time in the possession of the paymaster. In 1782 it was deprived of these extraordinary emoluments, and the salary fixed at 4000*l.* a year. The paymaster is constituted by letters patent under the great seal; he is, ex officio, of the privy council, sometimes of the cabinet. In the Pay Office there are under him a deputy paymaster, accountant-general, cashier, and various assistants.

PAYMASTER OF THE HOUSEHOLD. An officer in the lord steward's department. This office has superseded that of the ancient cofferers. It has a salary of 450*l.* per annum.

PEACE, JUSTICES OF. *See* JUSTICES.

PEAK. In Naval language, the name given to the upper corner of those sails which are extended by a gaff, or by a yard crossing the mast obliquely; as the mizzen yard of a ship, &c.

PEARLASH. Impure carbonate of potash. *See* POTASH.

PEARLS. These are substances formed by certain bivalve Mollusks, consisting of concentric layers of a fine compact nacre, or substance identical with that which lines the inside of the shell; they are sometimes found free and detached within the lobes of the mantle, but most commonly adherent to the nacrous coat of the shell, which on that account is termed "mother of pearl." The species of bivalve which produces the most valuable pearls is the pearl oyster of Ceylon, *Meleagrina margaritifera*, Lam. A pure pearl is generally spherical, and has a white, or bluish, or yellowish white colour, with a peculiar lustre and iridescence, and consists of alternating concentric layers of membrane and carbonate of lime. When steeped in dilute muriatic acid, the carbonate is decomposed with effervescence, and films of membrane remain undissolved.

Pearls were in the highest possible estimation in ancient Rome, and bore an enormous price. *Principium culmenque omnium rerum pretii, margaritæ tenent.* (*Plin. Hist. Nat.* lib. ix. c. 35.) Their price in modern times has very much declined; partly, no doubt, from changes of manners and fashions, but more, probably, from the admirable imitations of pearls that may be obtained at a very low price. According to Mr. Milburn, a handsome necklace of Ceylon pearls, smaller than a

large pea, cost from 170*l.* to 300*l.*; but one of pearls about the size of peppercorns may be had for 15*l.*: the pearls in the former sell at a guinea each, and those in the latter at about 1*s.* 6*d.* When the pearls dwindle to the size of small shot, they are denominated *seed* pearls, and are of little value. They are mostly sent to China. One of the most remarkable pearls of which we have any authentic account was bought by Tavernier, at Catifa, in Arabia, a fishery famous in the days of Pliny, for the enormous sum of 10,000*l.*! It is pear-shaped, regular, and without blemish. The diameter is ·63 inch at the largest part, and the length from 2 to 3 inches. It is in the possession of the shah of Persia.

The pearl oyster is fished in various parts of the world, particularly on the west coast of Ceylon; at Tuticoreen, in the province of Tinnevelley, on the coast of Coromandel; at the Bahrein Islands, in the Gulf of Persia; at the Sooloo Islands; off the coast of Algiers; off St. Margarita, or Pearl Islands, in the West Indies, and other places on the coast of Colombia; and in the Bay of Panama, in the South Sea. Pearls have sometimes been found on the Scotch coast, and in various other places.

The pearl fishery of Tuticoreen is monopolized by the East India Company, and that of Ceylon by government. But these monopolies are of no value; as in neither case does the sum for which the fishery is let equal the expenses incurred in guarding, surveying, and managing the banks. It is therefore sufficiently obvious that this system ought to be abolished, and every one allowed to fish on paying a moderate licence duty. The fear of exhausting the banks is quite ludicrous. The fishery would be abandoned as unprofitable long before the breed of oysters had been injuriously diminished, and in a few years it would be as productive as ever. Besides giving fresh life to the fishery, the abolition of the monopoly would put an end to some very oppressive regulations enacted by the Dutch more than a century ago. (For full details respecting the pearl fishery, see the *Commercial Dict.*)

PEARLSINTER. In Mineralogy, a siliceous mineral found in volcanic tufa: it is also called *fiorite*.

PEARLSTONE. A variety of obsidian, a volcanic product of a pearly lustre: it is a silicate of alumina.

PEASTONE, or PISOLITE. A variety of limestone composed of globular concretions of the size of a pea.

PEAT. The natural accumulation of vegetable matter on the surface of lands not in a state of cultivation; always more or less saturated with water, and generally abounding in modifications of extractive matter, varying with the nature of the plants of which the peat is composed.

Peat is generally of a black or dark brown colour, or, when recently formed, of a yellowish brown: it is soft, and of a viscid consistence; but it becomes hard and darker by exposure to the air. It is generally more or less mixed with earthy substances. When steeped in water it gives out a brown liquor, more or less dark. When thoroughly dried it may be set fire to, and burns slowly, giving out a gentle heat without much smoke. This smoke communicates a peculiar flavour to all the articles with which it comes in contact; and this flavour is considered a characteristic of spirits which have been distilled in vessels heated by this kind of fuel, and also of malt, corn, and fish which have been dried by it. Peat abounds in every part of the world, but more especially in the cold moist climates of temperate regions. It covers many thousand acres in Ireland, and in the Highlands and western counties of the Lowlands of Scotland, and in the western counties of England; but all these bogs are rapidly disappearing, in consequence of being drained, and having their surfaces slightly covered with earth, and stirred and sown with grass seeds.

When peaty matter accumulates on the sides of declivities it is generally comparatively dry, and is then called hill-peat; but when peat accumulates on hollow places, or on flat surfaces, it is generally thoroughly saturated with water, and is then called peat-bog. In most cases the principal plant which forms the peaty matter is the *Sphagnum palustre* of Linnæus; a moss which is common on all moist peaty surfaces throughout Europe, and is frequent in many parts of North America. This moss continues growing upwards from the points of the shoots, while decay is advancing in a similar manner from their lower extremities; thus forming a thick close mass of vegetable matter, which rots below as it increases in height. The rotten part is frequently dug out and dried, to be used as fuel, or to be mixed with dung or lime and rotted into manure.

When peaty matter accumulates on a surface which abounds in springs, the water sometimes oozes out beneath the peat, and between it and the natural soil, in such quantities as to raise up the layer of peat, and float it off to a distance; sometimes carrying every thing before it, and ending by burying under it lands in a state of culture. About the middle of the 18th century, a remarkable irruption of this kind took place near Annan in Dumfries-shire; and such irruptions are frequent in Ireland. The circumstances favourable to the growth of peat are a soil abounding in springs, a flat surface or hollow surrounded by hills, and a moist climate. Hence peat-bogs are more abundant in Ireland, and in the western counties of Scotland, than in any other part of the British empire.

When an accumulation of peat has taken place in a level situation, or on a declivity not abounding in springs, the matter accumulated is comparatively dry, and is then called peat moss. One of the most remarkable peat mosses in Britain is the Flanders Moss, in Stirlingshire. It rests on a flat surface of excellent alluvial soil, of which it covers about 4000 acres. Great part of this peat moss, being quite light, has been cut into small pieces, and floated off by means of a stream of water to the sea; thus exposing the natural soil, and rendering it fit for culture. This operation was commenced at Blair Drummond, towards the end of the last century, by the celebrated Lord Kames, and is still continued by his son, Mr. Drummond.

PEATS. Peat bog cut out in small square or rectangular pieces, and dried for being used as fuel. These pieces are cut out with light spades in the summer season, spread abroad to dry, and afterwards carted home and put up in stacks, or heaps, which are thatched to exclude the rain. These peats are afterwards used as fuel, not only for domestic purposes, but for burning lime, and for heating kilns for drying corn, &c. To facilitate the drying of peat, the water is sometimes pressed out of the square pieces after they are cut, and thrown out of the bog, by a compressing machine, which also renders the material more compact and durable in the fire. Peats are also sometimes charred by a smothered combustion, so as to be rendered better adapted to serve as a substitute for pit-coal, coke, or charcoal, in smelting iron or other metals, in generating steam, &c. Attempts have been made to separate astringent matter from peat, and to use it in tanning leather.

PEAT SOIL. Peat in a state of decomposition, on which corn or other agricultural crops may be grown. The process of turning living peat into peat soil is greatly facilitated by draining, and by laying earth or lime on its surface, and afterwards mixing the earthy matter with the peat by ploughing or digging. In this manner every kind of peaty surface may be rendered available for agricultural purposes; and accordingly, in Ireland, in Lancashire, and in Ayrshire, good crops of corn, potatoes, and artificial grasses are produced on the surface of peat lands, which consist of a layer of peat from five to twenty feet in depth. The plants which thrive best on the surface of beds of peat of this description are those which extend their roots immediately under the surface. Hence few trees will thrive in such soils, with the exception of the spruce fir, the silver fir, the birch, and two or three kinds of willows. Peaty soil is extensively used in gardening, in the culture of plants which are found growing on this soil in a wild state.

Peat from wood, or *woody peat*, is a composition of the branches, trunks, and roots of trees, with their leaves, and the shrubs and plants which have grown up among them, which have lain so long in water as to have decayed into a mass soft enough to be cut with a spade. The colour is a blackish brown, like that of mossy peat; and it may be used as manure, for fuel, and for the growth of plants. Peat of this description is found in some parts of Holland, and also in the Vale of Kennett, in Berkshire; but is most abundant in North America, where it forms the soil in which many of the plants and trees of that country thrive with the greatest vigour. Wherever it can be found, it is the most suitable of all kinds of peat for garden purposes. This kind of peat is frequently burned for its ashes, both in Britain and Holland; and these, from the alkali they contain, are found an excellent manure.

Peat, sandy, or *sandy peat*, is mossy peat in a state of decay or mould, naturally mixed with sand brought over it, from soil lying above its level, or by the overflowings of rivers. It is used in gardening for the same purposes as heath soil.

PE'BBLES. A term applied to rounded nodules, especially of siliceous minerals, such as rock-crystal, agates, &c. Among opticians the term pebble generally means the transparent and colourless rock-crystal or quartz (pure silica), which is used as a substitute for glass in spectacles: its extreme hardness renders it more durable, and little apt to be scratched.

PE'CCARI. A Pachydermatous quadruped allied to the hog; but generically distinguished by the absence of the outer toe of the hind foot, and the presence of a peculiar gland, which exudes its secretion by an orifice situated on the back; whence Cuvier devised the name *Dicotyles* (two navels) for the genus. The incisor and molar teeth resemble those of the hog, but the canines do not project from the mouth. The metacarpal and metatarsal bones of their two middle and largest toes are confluent, as in the Ruminants; with which their stomach

also, divided into three compartments with cæcal appendages, presents a marked analogy. Two species of peccari are known, both natives of South America; viz. the collared peccari (*Dicotyles torquatus*), and the white-lipped peccari (*Dic. labiatus*, Cuv.).

PECHBLEND, or PITCHBLEND. An ore of uranium.

PECK. A measure of capacity containing two gallons, or the fourth part of a bushel. The imperial peck contains 554·55 cubic inches. *See* MEASURE.

PE'CORA. (Lat. pecus, *a sheep.*) The name given by Linnæus to an order of Mammals corresponding with the Ruminantia of Cuvier.

P'ECTEN (Lat. *a comb*), in Comparative Anatomy, is the vascular membrane, in structure resembling the choroid, plicated with parallel folds like the teeth of a comb, and extending, in the eyes of birds, from the back of the retina through the vitreous humour to, or near to, the crystalline lens, where it mostly terminates in a point. This organ resembles a flattened conical bag, whence it is also termed "marsupium."

In Zoology, the name is applied to the genus of bivalve shells commonly called "clams." They have a hinge like that of the oyster; but have been removed on account of their shell being inequivalve, semicircular, always regularly marked with ribs, which radiate from the summit of each valve to the circumference, and furnished with two angular productions, called "ears," which widen the sides of the hinge.

The animal is chiefly remarkable for the little dark green metallic globule which terminates most of the tentacles of the exterior row of those at the circumference of the mantle. These specks are conjectured to be rudimental ogans of vision, whence Poli was induced to call the soft parts of the pecten "argus."

PE'CTIN. (Gr. πηκτος, *coagulated.*) Also termed *Pectic Acid.* The gelatinizing principle of certain vegetables, such as currants, apples, &c. It may be abundantly obtained from some of the esculent roots, especially carrots, whence their excellence as an ingredient in soup. To obtain it from this source the carrots are rasped, and the pulp strongly pressed, so as to render it as dry as possible; in this state it is washed in repeated portions of cold soft water, till all soluble matters are removed from it. The pulp thus prepared is then boiled with 5 parts of bicarbonate of potash to every 100 of the washed pulp; the decoction is filtered, and chloride of calcium added to it, which forms a bulky precipitate of *pectate of lime;* this is well washed, and the lime removed by very weak muriatic acid. Pectin, or pectic acid, thus obtained, is in the form of a jelly, which forms insoluble compounds with the earths and several of the other metallic oxides. It seems doubtful whether this jelly is not a *product*, resulting from the action of the alkaline carbonate of the lignin of the carrot. It must, however, be easily formed; for when carrots are stewed or boiled for a length of time, they become very gelatinous. When pectic acid is boiled in a strong solution of potassa, oxalate of potassa is produced.

PECTINA'TUM TECTUM. (Lat. pecten, *a comb.*) In Architecture, a roof which has obtained this name from its shape resembling that of a comb, and contrived to throw off the rain water in two ways.

PECTINIBRANCHIATES, *Pectinibranchiata.* (Lat. pecten, and branchia, *gills.*) The name given by Cuvier to his sixth order of Gastropods. It is the most extensive division of that class, since it includes almost all the spiral univalve shells, as well as several which are merely conical. The order is thus characterized by Cuvier:— "The branchiæ, composed of numerous leaflets or fringes, ranged parallel like the teeth of a comb, are affixed in two or three lines (according to the genera) to the floor of the respiratory cavity, which occupies the last whorl of the shell, and which communicates outwards by a wide aperture between the margin of the cloak and the body. Two genera only — *Cyclostoma* and *Helicina* — have, instead of branchiæ, a vascular network clothing the ceiling of the cavity, in all respects the same as that of the order; and they are the only ones which respire the atmosphere, water being the medium of respiration to all the rest."

All the Pectinibranchiates have two tentacula and two eyes, raised sometimes on pedicles; a mouth in the form of a proboscis, more or less lengthened; and separate sexes. The penis of the male, attached to the right side of the neck, cannot in general be drawn within the body, but is reflected into the branchial cavity; it is sometimes very large. The *Paludina* alone has the organ concealed, and it comes out through a hole pierced in the right tentaculum; the rectum and the oviduct of the female also creep along the right side of the branchial cavity; and there is between them and the branchiæ a peculiar organ, composed of cells filled with a very viscous fluid, the use of which is to form a common envelop for the inclosure of the eggs, and which the animal deposits within them. The form of that envelop is often very complicated and very remarkable.

The tongue is armed with little hooks (or curved spinules), and wears down the hardest bodies by slow and oft-repeated frictions.

The grand difference between these animals lies in the presence or absence of the canal formed by the prolongation of the margin of the branchial cavity on the left side, and which passes along a similar canal or sinus in the shell, to enable the animal to breathe without leaving its shell. There is also this distinction between the genera, that some want the operculum; and the species vary in the filaments, fringes, and other ornaments that deck the head, the foot, or the cloak.

PE'CTORALS, or PECTORAL FINS. (Lat. pectus, *the breast.*) The anterior and lateral pair of fins, which represent, in fishes, the fore legs or anterior members of other vertebrate animals.

PECULA'TION. (Lat. *peculium.*) A term of the Roman law, rendered in that of France by *concussion.* The embezzlement by a public officer of public money. Peculation, in the Roman law, also comprehended offences relating to the coin.

PECU'LIAR. In Ecclesiastical Law, an exempt jurisdiction, which is not under the ordinary of the diocese, but has one of its own. They are,—royal, of which the king is ordinary; peculiars of archbishops, bishops, deans, chapters, prebendaries, and the like; to which were formerly added peculiars of monasteries, the jurisdiction over which, by 31 H. 8. c. 13., was granted to the ordinary within whose diocese they were situate, or to such persons as the king should appoint.

PE'CULIUM. (Lat.) In the Roman Law, the property which a slave might acquire independent of the control of his master. This property was frequently permitted to accumulate, so as to enable the slave to purchase his freedom. The son being, on the principles of the Roman law, unemancipated during the lifetime of his father, whatever property he might acquire appertained in strictness to the latter; but, by degrees, certain species of property acquired by the child obtained the title and character of *peculia.* Of these, however, the only one which was absolutely the child's was that which the son acquired in military service (peculium castrense), or in public service of any kind, which by a legal fiction was regarded as equivalent to military.

PE'DAGOGUE. (Gr. παιδαγωγος; from παις, *boy*, and αγωγος, *leader.*) Among the ancient Greeks, a slave charged with the personal care of a boy from the earliest age after infancy (from the milk, in the loose phrase of Plutarch; from about the age of seven, as it is more accurately stated by Æschines) until he became a youth (μειρακιον), *i. e.* until the seventeenth or twentieth year. The pedagogue's duty was to attend his charge on all occasions when he left his father's house; to the lecture rooms of masters, the theatre, &c. (See especially Plato, *Sympos.*) He was also intrusted with the duty of instructing and disciplining the child in inferior branches of education and ordinary manners. He was, consequently, of a very superior order of common slaves, and must be understood as excepted when Aristotle recommends that a child should be left to converse as little as possible with persons of the servile class. (*Politic.* vii. 156.) The custom of entrusting children to slaves in this manner was common in other Grecian states; the Romans also employed a slave for similar purposes, with the title of *custos* or *magister.*

In modern times, and especially in Germany, the word *pedagogic* is used to signify the science or art of education.

PEDAL HARMONIES. In Music, the same as *Organ Point*, which see.

PEDALMA'SCHI. A Turkish officer, whose duty consists in looking after the interests of the Sultan in cases of legacies. The Ottoman treasury receives through this officer a tithe of all bequests made to heirs male.

PE'DALS (Lat. pes, *a foot*), in such musical instruments as the organ, harp, and pianoforte, are either keys acted on by the feet of the performer (whence the name), to modify the tone of these respective instruments, or levers acting on the swell of the organ, and on the stops. The invention of the pedals or foot-keys of the organ is attributed to a German named Bernhard, who lived in the 15th century. It was long, however, before their utility and importance were acknowledged by other nations; and it is a singular fact that though England was the first to introduce the organ generally into the church, she was the last to adopt this invention. Within the last twenty years many improvements have been made in the construction of pedals, and few organs, except those of small dimensions, are now built without them. *See* ORGAN.

PE'DATE. In Botany, a palmate leaf, with the two lateral lobes themselves divided into smaller segments, the midribs of which do not run directly into the common central point; as in the leaf of *Arum dracunculus.*

PE'DESTAL. (Lat. pes, *a foot.*) In Architecture, the substruction to a column or wall. The component parts of a pedestal are three; the base, the die, and the cornice.

The whole height of a pedestal is from one quarter to one third of the height of the column, with its entablature.

PE'DICEL. (Lat. pes.) One of the ramifications of that part of a flower called the peduncle.

PEDICE'LLATES, *Pedicellata*. (Lat. pes.) The name of an order of Echinoderms, comprehending those which have the vesicular pedicellate organs, which are termed feet in this class, but which project from various parts of the surface of the body.

PE'DIMANES, *Pedimani*. (Lat. pes, and manus, *a hand.*) The name of a family of Marsupial animals, of which the opossum (*Didelphis*) is the type; they are distinguished by the opposable property of the hinder thumb or hallux, the fore feet being organized like those of ordinary Unguiculate quadrupeds.

PE'DIMENT. (Lat. pes.) In Architecture, the low triangular mass representing the gable of a roof over the front of a building, portico, door, window, &c.; though sometimes these ornaments are terminated upwards by segments of circles. A pediment is frequently ornamented with sculpture. The heights of pediments are seldom more than two ninths of their width.

PE'DIPALPS, *Pedipalpi*. (Lat. pes; and palpo, *I feel.*) A name given to a tribe of pulmonary Arachnidans, comprehending those which have the feelers in the form of pincers, or armed with a didactyle claw; as the scorpions.

PEDLAR. *See* HAWKER.

PEDO'METER, or PODOMETER. (Gr. πους, *the foot*, and μετρον, *measure.*) An instrument for the purpose of registering the number of paces taken by a man in travelling or walking, whence the distance is ascertained. It is usually in the form of a watch, and receives its movement from the motion of the body, so that it advances one division at each step. The number of divisions may be noted by an index or hand, in the same manner as the number of vibrations of a watch-balance. The best construction, or rather the only one now used in this country, is that of Mr. Payne, watchmaker, of Bond Street. *See* PERAMBULATOR.

PEDU'NCULATES, *Pedunculata*. The name of an order of Cirripeds, comprehending those which have the body supported by a flexible tubular stem.

PEDU'NCULUS. (Lat. pes, *a foot.*) That part of a branch or stem that immediately bears the flowers.

PEEP-O'-DAY BOYS. The well-known appellation of certain insurgents who appeared in Ireland in 1784. They obtained this name from visiting the houses of their antagonists, called *defenders*, at break of day in search of arms.

PEER. (From the Latin *par*, French *pair.*) Equal, which meaning it still retains in the language of the common law, as trial by jury is said to be by the peers, or equals, of the defendant. In this sense, the name remains as a relic of feudal institutions, according to which every rank of society formed an association for the purpose of mutual defence and the decision of disputes; as the tenants of a lord paramount or inferior, who met as equals (pares curiæ) in the court over which he presided. Hence, in the French monarchy, the highest vassals of the crown formed a rank apart, and were called pares or peers with reference to each other; and the designation became a title of honour. The peers of France differed in number at different periods of the early French monarchy, as their domains became united to the crown; but, according to heraldic theory, there are six temporal, —the Dukes of Burgundy, Aquitaine, and Normandy, and Counts of Flanders, Toulouse, and Champagne; and six spiritual,—the Archbishop of Rheims, and the Bishops of Laon, Beauvais, Noyon, Chalons, and Langres. In later times new peerages were created, as the duchy of Brittany and counties of Artois and Anjou. At last the title remained as a simple dignity; and Louis XIV. increased the number of dukes and peers (ducs et pairs) until at last they amounted to thirty-seven. They had no privileges except precedence, and a seat in the parliaments. On the restoration of Louis XVIII. hereditary peerage was established in France on the model of that of England, but was abolished in 1831; and the members of the present chamber of peers are nominated for life by the people. For the history and privileges of the English peerage, see PARLIAMENT. There is a curious analysis of the English peerage in the *Quart. Review*, vol. 41.

PE'GASUS. In Greek mythology, a winged horse, produced by Neptune; or, according to some authors, which sprung from the blood of Medusa when Perseus cut off her head. *See* BELLEROPHON.

PEGASUS. This name is applied, in Zoology, to a genus of Lophobranchiate fishes with large pectoral fins, by means of which they are enabled to take short saltatory flights through the air.

PEGASUS. One of the 48 ancient constellations of Ptolemy, situated in the northern hemisphere.

PELA'GIANISM. The religious system promulgated by Pelagius, a British monk of the fifth century, who after attaining to considerable notoriety in his own day, by first eliciting the discussion of the great questions respecting grace and predestination, has succeeded in bequeathing his name as a designation in all after ages for those who have held the extreme opinions by which he was distinguished. His tenets are thus clearly stated by a modern writer:—"1. That the sins of our first parents are imputed to themselves alone, and not to their posterity; that we derive no corruption from their fate; that we inherit no depravity from our origin, but enter into the world as pure and unspotted as Adam at his creation. It was a necessary inference from this doctrine that infant baptism is not a *sign* or *seal* of the remission of sins, but only a mark of admission into the kingdom of Christ. 2. That our own powers are sufficient for our own justification; that as by our own free will we run into sin, so by the same voluntary exercise of our faculties we are able to repent and reform, and raise ourselves to the highest degree of virtue and piety; that we are indeed assisted by that external grace of God which has taught us the truths of revelation, which opens to us our prospects, and enlightens our understanding, and animates our exertions after holiness; that the internal or immediate operation of the Holy Spirit is not necessary either to awaken us to religious feeling, or to further us in our progress towards holiness; in short, that man, by the unassisted agency of his natural perfections, under the guidance of his own *free will*, is enabled to work out his own salvation." (*Waddington's Hist. of the Church.*) These opinions were formally condemned by a decree of Pope Zosimus, about 418, and again by the council of Ephesus, in 431. Their principal opponent was the famous Augustin, who, in the course of his arguments against them, advanced an explanation of the questions involved in the discussion, which has been stigmatized as leading directly to the opposite extreme of fatalism. (See *Mosheim*, vol. ii. cent. 5.) The Pelagian opinions respecting original sin are condemned in the 9th article of the English church.

PELECA'NIDÆ. The name of a family of swimming birds, of which the pelican (*Pelicanus*) is the type.

PELLA'GRA. (Lat. pellis, *the skin*, and æger, *sick.*) A disease of the skin somewhat resembling *elephantiasis*, and occasionally producing great constitutional derangement. It is endemic in certain districts of Italy, especially in the Milanese.

PE'LLICLE. (Lat. pellis, *skin.*) A thin membrane. In Chemistry, the term is applied to the film of salt or other substances which forms upon the surface of solutions during evaporation.

PE'LLITORY OF SPAIN. The root of the *Anthemis pyrethrum*. It has a pungent flavour, and when chewed promotes the flow of saliva, and is often useful in toothach.

PE'LTA. (Lat. *a shield.*) In Botany, a term used in describing lichens to denote a flat shield without any elevated rim, as in the genus *Peltidea*.

PELTA'STÆ. Light-armed infantry were so named among the Greeks, from carrying the pelta or target. (See *Mem. de l'Ac. des Inscr.*, vol. xxxii.)

PE'LTATE. (Lat. pelta, *a shield.*) A leaf or any other organ which is fixed to the stalk by the centre, or by some point distinctly within the margin, as in the *Tropæolum*.

PE'LTRY. (Germ. peltz, from Lat. pellis, *a skin.*) The name given to the skins of different kinds of wild animals found in high northern latitudes, particularly in America; such as the beaver, sable, wolf, bear, &c. When the skins of such animals have received no preparation, they are termed *peltry*; but when the inner side has been tanned by an aluminous process, they are denominated *furs*.

PE'LVIS. (Gr. πελυς, *a basin.*) The inferior part of the abdomen, the bony circumference of which is formed by the two *ossa innominata*, the *sacrum*, and the *os coccygis*. It contains the rectum, the urinary bladder, and internal organs of generation.

PE'MPHIGUS. (Gr. πεμφιξ, *a vesicle.*) A fever attended by almond-shaped vesicular eruptions.

PE'NALTY (Lat. pœna, *punishment*), is of three kinds, says Lord Coke; *pœna pecuniaria*, *pœna corporalis*, and *pœna exilii*. Where any thing is prohibited by statute under a penalty, if the penalty, or part of it, be not appointed by the statute to the informer, it goes to the crown. Penal statutes are to be construed strictly. *See* STATUTE.

PE'NANCE. *See* PENITENCE.

PENA'TES. The household gods of the ancient Italians, who presided over families, and were worshipped in the interior of each dwelling. The term is derived from penitus, *within*. Penates is in fact a generic term, comprising in its strict sense all the gods worshipped in the interior of the house, and consequently including the Lares, with whom they are continually mentioned in conjunction. The number and names of the Penates were indeterminate. As there were public as well as domestic Lares, so there were public Penates, who exercised a general influence over the destinies of the whole Roman people. Thus Tacitus relates, that "delubrum Vestæ cum

Penatibus populi Romani" was consumed, along with other very ancient temples, in the great fire during the reign of Nero. But the term may, perhaps, be considered as belonging to the rhetorical style of that author, and to signify merely the tutelary god of the republic.

The subject of the domestic deities of the Romans, the Lares and Penates, is involved in great obscurity, from the conflicting statements of the classic authors respecting them. Those who wish to see the question investigated in all its bearings may consult *Müller's Etruscans*, vol. ii. p. 90. &c.; Jaekel, *De Diis Domesticis;* Hartung, *Religion der Römer*, &c. (See also the notes by Prof. Ramsay of Glasgow, appended to his valuable little work entitled *Elegiac Extracts from Tibullus and Ovid, with English Introductions and Notes*, 12mo. 1840.)

PE'NCIL. (Lat. penicillum.) In Painting, Drawing, &c., the instrument wherewith the colours are applied. Pencils are of various sorts, sizes, and materials, suited to the nature of the work. The *black lead pencil* is made of long slips of black lead (plumbago or graphite), inclosed in cylindrical pieces of cedar, and is too well known to need further description.

PENCIL OF LIGHT, in Optics, is a collection of the rays or evanescent streams of light converging to a point, as the focus of a lens or mirror.

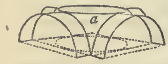
PE'NDANT. (Lat. pendo, *I hang.*) In Gothic Architecture, an ornamented polygonal piece of stone or timber hanging down from the vault or roof of a building. Of stone pendants some exquisite examples may be seen in Henry VII.'s Chapel at Westminster. In ancient writers the springers of arches, which rest on shafts or corbels, are called *pendants.*

Pendants of a Ship, are those streamers or long colours which are split or divided into two parts ending in points, and hang at the mast head or at the yard-arm ends.

PE'NDANT. In Painting, &c., a picture or print which, from uniformity of size and subject, seems to hang up as a companion to another. The term may also be applied to bassi rilievi of similar sizes.

Pendant is also the general term for all kinds of ornaments worn in the ears by both sexes in savage, and by females chiefly in civilized countries; usually termed ear-rings, which see.

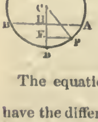
PENDE'NTIVE. (Lat. pendo, *I hang.*) In Architecture, the portion of a vault between the arches under a dome, called by the French *fourche*, or *panache*, lettered *a* in the diagram, by which it will be seen that it falls at its superior part into a circle inscribed in the square formed on the plan of the four arches. Hence it is obvious that a dome may be formed by means of pendentives over any regular polygon.



PE'NDULUM. (Lat. pendulus; from pendo, *I hang.*) If any heavy body, suspended by an inflexible rod from a fixed point, be drawn aside from the vertical position, and then let fall, it will descend in the arc of a circle of which the point of suspension is the centre. On reaching the vertical position it will have acquired a velocity equal to that which it would have acquired by falling vertically through the versed sine of the arc it has described, in consequence of which it will continue to move in the same arc until the whole velocity is destroyed; and, if no other force than gravity acted, this would take place when the body reached a height on the opposite side of the vertical equal to the height from which it fell. Having reached this height it would again descend, and so continue to vibrate for ever; but in consequence of the friction of the axis, and the resistance of the air, each successive excursion will be diminished, and the body soon be brought to rest in the vertical position. A body thus suspended, and caused to vibrate, is called a *pendulum;* and the passage from the greatest distance from the vertical on the one side, to the greatest distance on the other, is called an oscillation.

In order to investigate the circumstances of the motion, the body must be regarded as a gravitating point, and the inflexible rod as devoid of weight. This is denominated the *simple pendulum;* and the problem to be resolved is to determine the motion of a point constrained to move in a circular arc in virtue of the accelerating force of terrestrial gravity.

Let C be the fixed point, A D B the arc described by the pendulum, C D the vertical, and P the place of the pendulum at a given instant. Draw P E perpendicular to C D, and put D E $= x$, E P $= y$, the arc D P $= s$, D H (the versed sine of the arc D A) $= h$, and the radius C D $= l$; also let $v =$ the velocity at P, and $t =$ the time of descent through A P.



The equation of the circle being $y^2 = 2\,l\,x - x^2$, we have the differential equation $d\,s = \dfrac{l\,d\,x}{\sqrt{(2\,l\,x - x^2)}}$; and, by the doctrine of falling bodies, the velocity at P is that which a body would acquire in falling through H E, or equal to $\sqrt{2\,g\,\text{H E}}$ (g being the accelerating force of gravity): therefore $v = \sqrt{2g\,(h - x)}$. But $d\,t = \dfrac{d\,s}{v}$: therefore, on substituting the values of $d\,s$ and v above given, we get the equation

$$d\,t = \frac{l}{\sqrt{2\,g}} \cdot \frac{d\,x}{\sqrt{\{(h - x)\,(2\,l\,x - x^2)\}}}$$

This equation, being developed and integrated, gives the time of descent from A to D, or the time of a semi-oscillation, as follows (π being the ratio of the circumference to the diameter, or $= 3{\cdot}14159$):—

$$\frac{\pi}{2}\sqrt{\frac{l}{g}}\left[1 + \left(\frac{1}{2}\right)^2 \frac{h}{2\,l} + \left(\frac{1{\cdot}3}{2{\cdot}4}\right)^2 \left(\frac{h}{2\,l}\right)^2 + \&c.\right]$$

When the arc of vibration is small, it is only necessary to take account of the first two terms of the series; whence the time of a whole oscillation from A to B, which we shall denote by T, is given by the formula—

$$\text{T} = \pi\sqrt{\frac{l}{g}} \times \left(1 + \frac{h}{8\,l}\right);$$

and if the arc is so small that h (its versed sine) becomes evanescent in comparison of $8\,l$, we have simply $\text{T} = \pi\sqrt{\dfrac{l}{g}}$. Whence it appears that the time of an oscillation in an infinitely small arc is directly as the square root of the length of the pendulum, and inversely as the square root of the accelerating force of gravity.

Suppose gravity to be a constant force (as it is at any given place on the earth's surface), the time of oscillation is proportional to the square root of the length of the pendulum; consequently, if T′ denote the time of oscillation of a seconds' pendulum, and l' its length, we have $\text{T} : \text{T}' :: \sqrt{l} : \sqrt{l'}$. Now, let N be the number of oscillations the first pendulum makes in a given time, and N′ the number the second makes in the same time; then the number of oscillations being evidently in the inverse ratio of the times, we have $\text{N} : \text{N}' :: \text{T}' : \text{T}$; or $\text{N} : \text{N}' :: \sqrt{l'} : \sqrt{l}$, whence $l = \dfrac{\text{N}'^2}{\text{N}^2}\,l'$; so that if the length of one pendulum be known, we can compute the length of another pendulum by observing the number of oscillations that each makes in any given time; for example, an hour.

In like manner, if we suppose the same pendulum to be transported to different parts of the earth (in which case l is constant and g variable), and assume that the values of N and g at the first station become respectively N′ and g' at the second, we shall have $\text{T} : \text{T}' :: \dfrac{1}{\sqrt{g}} : \dfrac{1}{\sqrt{g'}}$; whence $g' = \dfrac{\text{T}^2}{\text{T}'^2}g$; or $g' = \dfrac{\text{N}'^2}{\text{N}^2}g$. So that the force of gravity at different places may be compared by observing the number of oscillations which a pendulum makes at each place in a given time. Or, if we suppose the times of oscillation constant (that is, if we suppose two pendulums so adjusted as to beat seconds at two different stations), and l and g variable; then, since $\text{T} = \pi\sqrt{\dfrac{l}{g}}$, and $\text{T}' = \pi\sqrt{\dfrac{l'}{g'}}$, we shall have $\dfrac{l}{g} = \dfrac{l'}{g'}$; or $l' = l\dfrac{g'}{g}$; whence the length of the seconds' pendulum at any place is directly proportional to the intensity of gravity at that place.

According to the theory of falling bodies (*see* GRAVITY), the time t in which a body falls through the space s, by the accelerating force of gravity, is given by the equation $t = \sqrt{\dfrac{2\,s}{g}}$. Let $2\,s = l$; then $t = \sqrt{\dfrac{l}{g}}$. But the time T, of the oscillation of a pendulum whose length is l, is $\text{T} = \pi\sqrt{\dfrac{l}{g}}$. therefore $\text{T} : t :: \pi : 1$; consequently the time of the oscillation of a pendulum is to the time that a heavy body would fall freely by the force of gravity through half its length, as the circumference of a circle to its diameter.

If we suppose the time to be expressed in seconds, and make $\text{T} = 1$, we shall have $g = \pi^2\,l$. Now Captain Kater found the length of the simple pendulum at London to be 39·13929 inches, and we know that $\pi^2 = 9{\cdot}8696$; therefore $g = 9{\cdot}8696 \times 39{\cdot}139 = 386{\cdot}29$ inches, or $g = 32{\cdot}2$ feet. It follows, therefore, that the space through which a body falls freely at London in a second of time is 16·1 feet.

Compound Pendulum.—The simple pendulum, as above defined, is only a theoretical abstraction; for the oscillating body can neither be so small that it may be regarded as a mathematical point, nor can the rod be entirely devoid of weight. When the body has a sensible magnitude, and the suspending rod a sensible magnitude and weight, as they must have in all actual constructions, the apparatus is called a *compound pendulum;*

and instead of being supported by a single point it is supported by an axis, or by a series of points situated in the same straight line. According to this definition, any heavy body oscillating about an axis of suspension is a compound pendulum.

In every compound pendulum there is necessarily a certain point at which if all the matter of the pendulum were collected the oscillations would be performed in exactly the same time. This point is the centre of oscillation. (*See* Centre of Oscillation.) It is situated in the vertical plane passing through the centre of gravity of the pendulum, and at a distance from the axis of suspension (the axis being always supposed horizontal), which is determined by the following formula: — Let dm be the element of the mass of the compound pendulum, r its distance from the axis of rotation, and x the distance of the centre of oscillation from the same axis; then

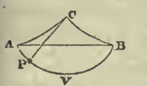
$$x = \int r^2\, dm \div \int r\, dm;$$

that is, the distance of the centre of oscillation from the axis of suspension is equal to the moment of inertia of the oscillating body divided by its moment of rotation. This value of x is the length of the isochronous simple pendulum, and is what is always to be understood by the term *length of a pendulum*.

The centre of oscillation possesses a very remarkable property, which was discovered by Huygens; namely, that if the body be suspended from this point, or a horizontal axis passing through it parallel to the former axis of suspension, its oscillations will be performed in the same time as before; in other words, the axes of suspension and oscillation are interchangeable. This property furnishes an easy practical method of determining the centre of oscillation, and thence the length of a compound pendulum.

Applications of the Pendulum. — The most important application that has been made of the pendulum is to the measurement of time. It is said that Galileo, while a young man, having had his attention drawn to the oscillations of a lamp suspended from the roof of a church in Pisa, perceived that, although their extent was gradually diminished, they continued to be made in equal times, and thence conceived the idea of employing a pendulum as a means of measuring small intervals of time in astronomical observations. But though a pendulous body, by the isochronism of its oscillations, furnishes a means of dividing time into equal portions, it could obviously be of no great use until a method was devised of continuing the motion, and registering the number of oscillations. The application of clock-work to this purpose has been claimed for various individuals, but is generally and deservedly ascribed to Huygens; and the invention, one of the most important that ever was made in reference to practical astronomy, dates from the year 1656.

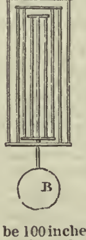
Huygens' researches on the subject of the oscillations of the pendulum are contained in his admirable work entitled *Horologium Oscillatorium*. He soon found that the oscillations in circular arcs of different amplitudes are not equal, the wider requiring rather a longer time than the narrower; and, with a view to remedy this defect, he undertook to investigate the nature of the curve in which the oscillations would be performed in equal times, whatever might be the extent of the arc described. The curve possessing this remarkable property was found to be the cycloid. (*See* Cycloid.) The next object was to devise a means of causing a pendulum to vibrate in such a manner that its centre of oscillation shall describe the arc of a cycloid. This was also effected by Huygens by the following construction, which depends on another property of the cycloid, namely, that its evolute is a similar curve: — If A C and B C be two semicycloids, or semicycloidal cheeks, each equal to the half of A V B, touching A B in A and B, and meeting one another in C; and if there be fixed at C a pendulum P, hanging by a thread P C, equal in length to the semicycloid; then P, in its oscillations, will describe the cycloidal arc A V B. Nothing more simple or beautiful in point of theory could be conceived than this construction; but, on attempting to reduce it to practice, it was soon found to possess no advantage, in consequence of the mechanical difficulty of making the cycloidal cheeks with the requisite accuracy, and the impossibility of obtaining a flexible string of invariable length. Huygens himself showed that the error of a hundredth of an inch in the form of the curve would cause a greater irregularity than a circular vibration of 10 or 12 degrees. Accordingly, the use of cycloidal cheeks was abandoned, and the attention of artists directed to the means whereby the oscillations might be confined within very small circular arcs, in which case any inequality in the lengths of the arcs becomes insensible. In clocks of the best construction the arc of vibration is very small; and the pendulum is made very heavy, in order that, by possessing a great momentum, it may be less affected by the imperfections of the machinery.



Compensation Pendulum. — The value of the pendulum as a regulator of timepieces depends on the isochronism of its oscillations; which, in its turn, depends on the invariability of the distance between the points of suspension and oscillation. But, as every known substance expands with heat and contracts with cold, the length of the pendulum will vary with every alteration of temperature, and the rate of the clock consequently undergo a corresponding change. To counteract this variation, numerous contrivances have been employed. The principle is, however, the same in all; and consists in combining two substances, whose rates of expansion are unequal, in such a manner that the expansion of the one counteracts that of the other, and keeps the centre of oscillation of the compound body always at the same distance from the axis of suspension. A brief description of the two compensation pendulums in most common use — the *Mercurial Pendulum* and the *Gridiron Pendulum* — will sufficiently explain the means by which compensation is obtained.

Mercurial Pendulum. — This was the invention of Mr. George Graham, a celebrated watchmaker, who subjected it to the test of experiment in the year 1721. The rod of the pendulum is made of steel, and may be either a flat bar or a cylinder. The bob or weight is formed by a cylindrical glass vessel, about 8 inches in length and 2 inches in diameter, which is filled with mercury to the depth of about $6\frac{1}{2}$ inches. The cylinder is supported and embraced by a stirrup, formed also of steel, through the top of which the lower extremity of the rod passes, and to which it is firmly fixed by a nut and screw on the end of the rod. Now the effect of an increase of temperature on this apparatus is evidently as follows: — In the first place, the rod expands, and the distance between the axis of suspension and the bottom of the stirrup is increased. In the second place, by the expansion of the mercury in the cylinder, its column is lengthened, and the distance of its centre of gravity from the bottom of the stirrup consequently increased. But, as the expansion of mercury is about sixteen times greater than that of steel, the height of the mercurial column may be so adjusted by trial that the expansion of the rod and stirrup shall be exactly compensated by that of the mercury, and the centre of oscillation of the whole suffer no change. This pendulum is, perhaps, the most perfect of all compensators; but, as its adjustments are attended with considerable difficulty, it is seldom used excepting in astronomical observatories.

Gridiron Pendulum. — This was contrived by Mr. Harrison, the inventor of the chronometer. It consists of a frame of nine parallel bars of steel and brass, arranged and connected as in the annexed figure. The bars marked *s* are of steel; the four marked *b* are of brass; the centre rod, of steel, is fixed at top to the cross bar connecting the two middle brass rods, but slides freely through the two lower bars, and bears the bob B. The remaining rods are fastened to the cross pieces at both ends, and the uppermost cross piece is attached to the axis of suspension. It is easy to see, from the mere inspection of the figure, that the expansion of the steel rods tends to lengthen the pendulum, while that of the brass rods tends to shorten it; consequently, if the two expansions exactly counteract each other, the length of the pendulum will remain unchanged. The relative lengths of the brass and steel bars are determined by the expansions of the two metals, which are found by experiment to be, in general, nearly as 100 to 61. If, then, the lengths of all the five steel bars added together be 100 inches, the sum of the lengths of the four brass bars ought to be 61 inches. When the compensation is found on trial not to be perfect, an adjustment is made by shifting one or more of the cross pieces higher on the bars.



Harrison's pendulum has been greatly improved by Troughton, who substituted for the two pair of brass rods two cylinders of brass, sliding the one within the other, to which the steel rods are attached. For a description of this, and various other modes of compensation, we refer the reader to an excellent chapter on the subject by the late Captain Kater, in the volume of *Mechanics* in the *Cabinet Cyclopædia*.

Application of the Pendulum to the Determination of the relative Force of Gravity at different Places. — There are two methods of determining the relative intensity of gravity by means of the pendulum. According to the first, the absolute length of the simple pendulum which makes a certain number of oscillations in a given time is accurately ascertained at each of the places, and the comparative force of gravity is then given by the formula $g' = \frac{l'}{l}g$. According to the other method, an invariable pendulum is swung at the different places, and

the number of its oscillations noted at each, when the relative gravity is given by the formula $g' = \frac{N'^2}{N^2} g$. Each of these methods has been followed in the delicate experiments which have been made for the purpose of determining the figure of the earth; but though the results of both appear to be nearly equal in point of accuracy, the latter method, on account of its affording greater facilities in practice, is now generally adopted.

It will readily be conceived that a pendulum would be altogether unfit for the purpose of determining the minute variations of gravity if it were attached to a clock, or any machinery by which its motions could be influenced. It must be suspended from a very firm support, to which it can communicate no vibratory motion; and the most delicate precautions are necessary to avoid the effects of friction, and other disturbing causes, by which the experiment may be influenced. The method followed by the French astronomers, in their operations connected with the measurement of the meridian, was this: — The pendulum was composed of a sphere of platinum, suspended by a slender iron wire from a knife edge of hardened steel resting on plane surfaces of polished agate. It was placed in front of a well-regulated astronomical clock, with which its oscillations were compared, and the distance between its centres of suspension and oscillation determined by calculation from the length of the wire and the diameter of the sphere, ascertained by actual measurement. A different, and in many respects preferable mode of measuring the lengths of the seconds' pendulum, was adopted by Captain Kater, grounded on the property of oscillating bodies discovered by Huygens; namely, that the centres of suspension and oscillation are convertible. From this property it follows that if two knife edges, turned in opposite directions, are inserted in the same pendulum, and the mass be so adjusted, by means of a moveable weight sliding on the rod, that the oscillations are performed in exactly equal times when the pendulum is suspended from either knife edge, then the distance between the knife edges is the true length of the isochronous simple pendulum. In this manner the measurement is effected more directly, and no calculation is required for finding the centre of oscillation. A third method, lately put in practice by the celebrated astronomer Bessel, consists in suspending a ball and wire first from the upper end and then from the lower end of a rod of a given length, the ball being in both cases at the same distance below the rod. From the difference of the times of oscillation of the two pendulums thus formed, the length of the simple pendulum can be computed in terms of the rod, which is the difference of their lengths. The French method is described, with all the requisite details, in the third volume of *Base Métrique*, in *Delambre's Astronomie*, tome iii.; and in the *Recueil d'Observations Géodésiques, &c.*, by Biot and Arago, Paris, 1821. Captain Kater's pendulum is described in the *Phil. Trans.* for 1818; and Bessel's in his *Untersuchungen über die Länge des einfachen Secundenpendels*, Berlin, 1828.

Captain Kater's pendulum was formed of a very thin bar of plate brass, with a heavy bob and moveable weight, by means of which the isochronism was obtained when the suspension was made from the opposite knife edges. But a much simpler modification has been adopted in the recent experiments. The experimental pendulums of the Royal Astronomical Society consist merely of a plain straight bar of iron or copper, 2 inches wide, half an inch thick, and about 62¼ inches long. At the distance of 5 inches from one end of the bar is placed the apex of one of the knife edges, A; and at the distance of 39·4 inches therefrom the apex of the other knife edge, B; and the required adjustment to synchronism is produced by filing away one of the ends of the pendulum until the vibrations are found by trial to be equal in both positions of the pendulum. It is obvious that, for the purpose of merely ascertaining the variations of gravity, a bar of this form with a single knife edge would equally answer the purpose; but the advantage of the double suspension is this, that besides having two distinct and independent pendulums, each of which is a check upon the other, it furnishes the means of ascertaining whether the pendulum has sustained any accidental injury, which would be immediately discoverable from the inequality of the number of vibrations between the two knife edges.

Corrections. — In order that the results of different sets of experiments may be exactly comparable with each other, several corrections must be applied. The first of these is on account of the length of the arc of vibration, which, being of a finite and variable extent, the duration of the oscillations is consequently unequal, but always greater than in the case of an infinitely small arc. The number of oscillations is reduced to the case of an infinitely small arc by the formula

$$N \times \frac{M \sin. (A + a) \sin. (A - a)}{32 (\log. \sin. A - \log. \sin. a)}$$

where N is the number observed, M the logarithmic modulus = ·4342945, A the initial, and a the final arc of vibration; and as the arcs are always small, the computation may be shortened by using the arcs instead of the sines.

In the second place, all the experiments must be reduced to a common standard of temperature, which, in this country, is assumed at 62° of Fahrenheit. Let e denote the rate of expansion of the metal, t the mean height of the thermometer at the time of the experiment; then the correction of the number of vibrations on account of the temperature is $N \times \frac{1}{2} e (t - 62°)$.

A third correction is required on account of the atmospheric pressure. The effect of the pressure of the atmosphere on the pendulum is to diminish the force of gravity in the ratio of the specific gravity of the pendulum to that of the air; and on this principle the correction was formerly applied, regard being had to the height of the barometer. But it was recently remarked by Bessel that the pendulum drags with it a certain portion of air, the amount of which depends on the form of the pendulum; and, consequently, the specific gravity of the actually moving mass cannot be previously computed, but must be ascertained for each pendulum by actual experiments in air and in a vacuum. See a paper on this subject by Mr. Baily, in the *Phil. Trans.* for 1832. Also *Memoirs of the Royal Astr. Soc.* vol. vii.

Application of the Pendulum to the Determination of the Figure of the Earth. — The ellipticity of the earth is deduced from the observed number of oscillations made by an invariable pendulum at different latitudes, by means of the following theorem: — Let N = the number of oscillations made by a pendulum at the equator in a mean solar day, N′ = the number of oscillations made by the same pendulum at the latitude l, G = the force of gravity at the equator, and g = the same force at the latitude l; then, supposing the figure of the earth to be that of an oblate spheroid of revolution, we have $g = G (1 + n \sin.^2 l)$. But, by the property of the pendulum, $g : G :: N'^2 : N^2$; therefore, $N'^2 = N^2 (1 + n \sin.^2 l)$. In this equation the quantity n depends upon the centrifugal force of rotation at the equator, and the ellipticity; and, according to a theorem discovered by Clairaut, its value is $\frac{5}{2} m - e$, m being the ratio of the centrifugal force to gravity, and e the ellipticity. Newton showed that $m = \frac{1}{289}$, whence $n = \frac{5}{2 \times 289} - e$; therefore, as N'^2 is given by observation, the only unknown quantities in the equation $N'^2 = N^2 (1 + n \sin.^2 l)$ are N^2 and n: so that, by combining the results at two different latitudes, we can determine these quantities, and, consequently, e. The length of the seconds' pendulum being also proportional to the intensity of gravity, it is obvious that the lengths might be substituted in the above equation for N'^2 and N^2.

The seventh volume of the *Memoirs of the Royal Astr. Society* contains the results of experiments made with the invariable pendulum at 79 different latitudes. The values of N^2 and n, deduced from the whole of these results, are respectively

$$N^2 = 7441625711, \quad n = ·00514491;$$

whence the ellipticity deduced from the whole is $\frac{1}{285·26}$. It is remarkable that all the pendulum experiments agree in giving a greater ellipticity to the earth than is found by the comparison of measured arcs of meridian.

As the force of gravity varies inversely as the square of the distance from the centre of the earth, a correction is obviously required for the differences of altitude of the stations where the observations are made. Accordingly, the results at every station are reduced to what they would have been if the observations had been made at the level of the sea. Let h = the height of the station above that level, and R = the radius of the earth; g = the force of gravity at the station, and g' the same force at the level of the sea; then $g : g' :: R^2 : (R + h)^2$; whence, expanding the quantity $(R + h)^2$, and leaving out $\frac{h^2}{R^2}$ as insensible, we have $g' = g \left(1 + \frac{2h}{R}\right)$, in which we may substitute for g' and g either the lengths of the seconds' pendulum, or the square of the number of its oscillations at the station and the level of the sea. The result, however, is modified by the local attraction of the mass of ground surrounding the station, and Dr. Young assumes that the formula should be multiplied by the fraction ·6.

The following table, from Mr. Airy's treatise on the Figure of the Earth (*Ency. Metrop.*), shows the length of the seconds' pendulum in English inches at a few of the stations, where it has been actually determined. It is to be remarked, however, that some degree of uncertainty

attends all the results, on account of the error in the correction for the density of the air, which may amount to about ·0018 for each.

PENICI'LLATE, (Lat. penicillum, *a pencil.*) In Zoology, when a part supports one or more small bundles of diverging hairs.

PENI'NSULA. (Lat. pene, *almost*, and insula, *an island.*) A portion of land, as the term implies, nearly surrounded by water; as Africa, the Morea, California. In common parlance, the term Peninsula is usually applied to Spain and Portugal; and the struggle so long maintained between these countries, aided by the British, and the French, at the commencement of the present century, is called the Peninsular war.

PE'NITENCE, or PENANCE, in the Roman Catholic Church, is one of the seven sacraments. Priestly orders give the power to confer this sacrament; but, as a matter of discipline, their power is not exercised without authority from the Ordinary, either general or special, except in cases of necessity. The terms penitence and penance are likewise used for the good works commanded by a priest to a penitent, to be performed in satisfaction of the sins of which he absolves him. Public penance, in the earlier times of the church, was imposed for great offences committed after baptism. It consisted in exclusion from the church, solitude, prayer, and fasting, and the readmission was only gradual: the penitent being first allowed to approach the doors of the church; then to attend at sermons and readings, but not at prayers; then to pray, kneeling, &c. The time of penance varied according to different usages: St. Basil mentions two years for theft, seven for sensuality, fifteen for adultery, twenty for homicide, and the whole life for apostacy. Public penance for secret sins was generally remitted about the 7th century; and its commutation for the repetition of prayers and bestowing of alms began in the next. These alms were frequently applied by the penitent to the purchase of masses for himself or others. Afterwards the usage of pilgrimage as a mode of penance became general; and, finally, indulgences began to be sold in the 12th century.

PENITE'NTIARY. A prison in which convicted offenders are placed and subjected to a course of instruction and discipline, with a view to their reformation. Imprisonment after conviction is of two kinds: the simply repressive and penal, and that which is at the same time reformatory. But it is obvious that there is no advantage in attempting to produce the latter effect in those short imprisonments of a year or a few months, which form the ordinary punishments of our law for smaller offences. Crimes of a higher order are with us usually punished by transportation; and hence there is less room for the development of the penitentiary system among ourselves than in other European countries, and in the United States of America. At Genoa, the convict is only subjected to the penitentiary system at the end of the first year of his imprisonment: some writers on the subject recommend two years as a more appropriate limit for the commencement of this species of discipline. In England, the first act for the establishment of penitentiaries was passed in 1776, at the suggestion of the philanthropist Howard and judge Blackstone; and attempts were made in consequence, at Gloucester and other places, with little success. In 1812 the act was passed under which the Milbank prison was erected as a general penitentiary for England and Wales. It is now adapted to contain 800 male and 400 female prisoners. The chief object in penitentiaries, besides conferring moral and religious instruction on the prisoners, is to employ them in some useful labour; but there is always considerable difficulty in carrying into effect this part of the system, especially so as to reconcile it with the necessity of keeping prisoners separate as far as possible. At Milbank, tailoring forms the principal occupation of a large proportion of the inmates. *See* PRISONS.

PENITE'NTIARY, GRAND. An officer of the Roman Catholic church, usually a cardinal, appointed by the pope to grant absolution in cases reserved for the papal authority, dispensations for marriage, &c. In like manner, bishops appoint penitentiaries to perform the like office in such cases as are reserved for episcopal absolution. Briefs granted by the grand penitentiary are at the present time entirely gratuitous, and headed with the words "pro Deo."

PE'NITENTS. A name given in Roman Catholic countries to certain religious fraternities, distinguished by their particoloured garments. Of these there were a great variety in France, Spain, and Portugal, &c.; but the most extraordinary were the White Penitents, a body of fanatics, who appeared in the north of Italy in 1399, clothed in white, and bearing crucifixes, under the guidance of a priest, whose real history seems unknown, but concerning whom many strange stories were told; among others, that he professed to be the prophet Elias, and that his mission was to announce the immediate destruction of the world. The contagion of this outburst of religious feeling extended to Tuscany, and thence over the whole of Italy; and was accompanied by a general cessation of violence and private war. But it lasted only a few months. (Waddington, *Hist. of the Church*, p. 546., and the authors there referred to.)

PENNATULA'RIÆ. (Lat. penna, *a feather.*) The name of a family of Polypes, of which the sea-pen (*Pennatula*) is the type.

PE'NNON. A term sometimes poetically used for a streamer or banner; but restricted in the middle ages to the banner of a knight, baronet, or esquire.

PE'NNY. The twelfth part of a shilling. The penny was formerly a silver coin, first struck in England by the Saxons. It contained the 240th part of their pound, and its weight was about 22½ grains. Till the time of Edward the First the English penny was struck with a cross so deeply sunk in it that it might, on occasion, be easily broken and parted into halves, thence called halfpenny; or in four parts, thence called *fourthings*, or farthings. Edward the First also reduced the weight of the penny to a standard; ordering that it should weigh the 20th part of an ounce. It afterwards suffered successive diminutions, till, in the reign of Elizabeth, its value was reduced to the 62d part of an ounce of silver. This proportion is still observed.

PE'NNYWEIGHT. A weight equal to twenty-four grains, or the 20th part of an ounce troy. This was the weight of the silver penny in the time of Edward the First. *See* PENNY.

PENS. (Lat. penna, *a feather.*) Well-known instruments for writing, usually formed of the quills of the goose, swan, or some other bird. Metallic pens have been occasionally employed for a lengthened period; but it is only within these few years that they have been extensively introduced. They first began to be largely manufactured by Mr. John Perry, of London. Mr. P. having succeeded in giving to his pens a greater degree of softness and elasticity than was possessed by any metallic pens previously in use, they speedily obtained a very extensive sale. This success brought crowds of rivals into the field; so that metallic pens are now manufactured in vast quantities, and of an immense variety of forms. But though they have superseded to a very considerable extent the use of quills, and have some peculiar advantages, it does not appear possible to give them the elasticity of the quill, nor fit them so well for quick and easy writing. In the manufacture of steel pens the best metal, made from Dannemora or hoop (L) iron, is employed. It is laminated into slips about 3 feet long and 4 inches broad, of a thickness corresponding to the desired stiffness and flexibility of the pens. These slips are subjected to the action of a stamping-press, somewhat similar to that for making buttons. The point destined for the nib is next introduced into an appropriate gauged hole of a little machine, and pressed into the semicylindrical shape; where it is also pierced with the middle slit, and the lateral ones, provided the latter are to be given. The pens are now cleaned, by being tossed about among each other, in a tin cylinder about 3 feet long, and 9 inches in diameter; which is suspended at each end upon joints to two cranks, formed one on each of two shafts. The cylinder, by the rotation of a fly-wheel acting upon the crank-shafts, is made to describe such revolutions as agitate the pens in all directions, and polish them by mutual attrition. In the course of four hours several thousand pens may be finished upon this machine. (See *Commercial Dict.*, and *Ure's Dict. of Arts, &c.*)

PE'NSIONARY, THE GRAND, of Holland, was the prime minister of the states of the province of Holland. He proposed the measures to be discussed in the assembly of the states. He also transacted business with foreign ministers, and fulfilled other important functions. His term of service was five years, and he was capable of re-election.

PENSIONER. Literally, one who receives a pension or allowance. At the universities of Cambridge, however, and Dublin, this term has a peculiar meaning, being applied to those students who live at their own expense, *i. e.* without any support from the beneficent foundations of

the respective colleges. In this sense it is synonymous with commoner at Oxford.

PENTA'CRINITES. (Gr. πεντε, *five*, and κρινον, *lily.*) The name of a tribe of Echinoderms, comprehending those in which the animal consists of an angular, jointed, flexible column, fixed at the base, and supporting on its free extremity a concave disc or body, terminating in five dichotomizing, jointed, semicylindrical arms. Most of the species and genera of this tribe are extinct.

PENTADO'RON. (Gr. πεντε, and δωρον, *a palm.*) In Ancient Architecture, a brick of five palms in length, used by the Greeks in the construction of their public edifices.

PE'NTAGON. (Gr. πεντε, and γωνια, *angle.*) In Geometry, a plane figure, having five angles, or contained by five sides. It is a *regular* pentagon when the sides and angles are equal, and is consequently inscribable in a circle. The length of the side of a regular pentagon is equal to twice the sine of 36°, radius being unit; and its area $= 5$ sin. $36^{\circ} \times$ cos. 36°; or, making the side $= s$, the area $= \frac{5}{4} s^2 \times$ tan. 54°. It is a remarkable property of the regular pentagon, that the square of its side is equal to the sum of the squares of the sides of the hexagon and decagon inscribed in the same circle.

PENTAGRAPH. *See* PANTAGRAPH.

PENTAME'RANS, *Pentamera.* (Gr. πεντε, and μηρος, *a joint.*) The name of a section of Coleopterous insects, including those which have five joints on the tarsus of each leg.

PENTA'METER. (Gr. πεντε, and μετρον, *measure.*) A species of verse consisting of five feet or measures (whence the name), and which when subjoined to a hexameter verse constituted what is denominated *elegiac.* The scheme of the pentameter is as follows: —

– ⏖ | – ⏖ | – | – ⏑⏑ | – ⏑⏑ | – |

Or more properly thus,

– ⏖ | – ⏖ | – – | ⏑⏑ – | ⏑⏑ – |.

It must be observed, that the cæsural pause at the third foot must always terminate a word; and, as a general rule, the last word of the verse must consist of two syllables, although a quadrisyllable, especially in proper names, is sometimes admitted.

The first Greek elegiac writers were Callinus and Tyrtæus, who were followed by Mimnermus, Theognis, and Solon, in their own country; and by Catullus, Propertius, Tibullus, and Ovid, in Rome. The variety of themes sung by these different writers proves the capacity of this measure for adaptation to every subject, whether mournful, as the term *elegiac* would imply; or political and warlike, like the strains of Tyrtæus and Callinus; or erotic, like those of Propertius, Tibullus, and Ovid; or historical and mythological, like the *Fasti* of the last. The pentameter has not been generally introduced into any modern language with which we are acquainted; though Goethe and Schiller have left us some excellent specimens of the facility with which it might be engrafted on the German language. The hexameter and pentameter distich is beautifully described in the following lines of Schiller: —

Im Hexameter steigt des Springquells flüssige Säule:
Im Pentameter drauf fällt sie melodisch herab.

Thus admirably rendered by Coleridge, who was long considered as the original author: —

In the hexameter rises the fountain's silvery column:
In the pentameter aye falling in melody back.

Every page of Ovid's *Heroides*, or *Tristia*, illustrates the manner in which the hexameter breaks, as it were, and falls back in the pentameter, thereby adding a most exquisite grace to the rhythm: indeed the secret genius of the metre appears to consist in this play. The following instances, taken from Penelope's letter to Ulysses, will illustrate the truth of this observation: —

Troja jacet certe, Danais invisa puellis:
Vix Priamus tanti totaque *Troja* fuit.

Again,

Sive quis *Antilochum* narrabat ab Hectore victum;
Antilochus nostri causa timoris erat.

Besides this peculiarity in the pentameter, grammarians have pointed out several others, an observance of which is necessary to constitute a perfect pentameter. Of these perhaps the most important is the axiom, that although either a spondee or a dactyl may be used at pleasure in the first two feet of the verse, a dactyl should be preferred to a spondee whenever practicable; and a comparison of the ancient authors will show that on the frequent use of the former much of the beauty of this elegant measure depends. *See* HEXAMETER.

PENTA'POLIS. (Gr. πεντε, and πολις, *a city.*) A name given by the ancient Greeks to certain countries which were remarkable for having five distinguished cities; thus there was the Pentapolis of Lybia, Italy, and Asia Minor: but the most celebrated was the Pentapolis Cyrenaica (or of Egypt), whose five cities were Berenice, Arsinoe, Ptolemais, Cyrene, and Apollonia.

PE'NTASTYLE. (Gr. πεντε, and στυλος, *a column.*) In Architecture, a building having five columns in front.

PE'NTATEUCH (Gr. πεντατευχον; from πεντε, and τευχον, *an instrument*), signifies the five volumes of the books of Moses; viz. Genesis, Exodus, Leviticus, Numbers, and Deuteronomy.

1. The book of *Genesis* (as the term implies) gives an account of the creation of the world and of man; the fall of man; the flood; and the history of the Jewish patriarchs, Abraham, Isaac, and Jacob, down to Joseph (1750 B. C.). This book was looked upon with great veneration by the Jews, as comprising the history of their venerable founder Abraham, and his nearest descendants, — around whom many of their peculiar customs and laws were intertwined; but it is no less valuable to the Christian world, both from its venerable antiquity, and from its furnishing rich materials for historical, geographical, and antiquarian investigations. It contains, besides, numerous subjects for moral and religious reflections, which are referred to in many other later portions of the Old and New Testament. 2. The book of *Exodus* (Gr. εξ, and οδος, *a way*), narrates the fortunes of the descendants of Abraham after their migration to Egypt; the birth of Moses, and his endeavours to emancipate the Jewish nation from Egyptian bondage; their escape from Egypt; their journey through the wilderness; and the delivery of the law to Moses. This book, besides being peculiarly valuable in a religious point of view, possesses also great interest from marking the transition of the Jewish people from the pastoral or *nomadic* to the agricultural or *fixed* mode of life. 3. The book of *Leviticus* (so called from Levi, a priest), consists chiefly of the law and ordinances of the Jewish priesthood, or regulations as to the different kinds of sacrifices to be offered up; the duties of masters towards their slaves; regulations as to marriage, &c. It is replete with interesting antiquarian matter. 4. The book of *Numbers* (so called from its giving an account of the numbering of the people), contains besides an enumeration of many civil and ceremonial ordinances; and embraces an historical period of 38 years, chiefly relating to the captivity and the wilderness. 5. The book of *Deuteronomy* (Gr. δευτερος, *second*, and νομος, *law*), contains chiefly (as the origin of the term implies) a condensed summary of the laws and ordinances delivered in the three preceding books.

There are two ancient and authentic copies of the Pentateuch: the one written in Samaritan or Phœnician characters; the other in Chaldean, which was adopted by the Jews, in preference to the former, after their return from Babylon. The differences between the two are represented as not material; but it is imagined that some alterations and additions have been made in the Samaritan text, in order to favour the peculiar prejudices and claims of that people.

The Pentateuch was, down to a recent period, universally attributed to Moses; but some German theologians have attempted to prove, in our opinion with but little success, that Moses was not the author. There are no doubt several passages, especially in Deuteronomy, which could not possibly have been written by Moses; but these can easily be accounted for as interpolations of a copyist, and do not affect the authenticity of the whole Pentateuch. The chief arguments for the genuineness of the Pentateuch are ably given in the *Penny Cyclopædia*, to which we beg to refer the reader.

PENTA'THLIUM. (Gr. πεντε, and αθλος, *a contest.*) A general appellation given by the Greeks to their five chief bodily exercises; viz. running, leaping, throwing the quoit or discus, hurling the javelin, and wrestling. These five exercises were termed *Quinquectium* by the Romans.

PE'NTECOST. (Gr. πεντηκοστος, *fiftieth.*) A Jewish festival; so called because it was observed on the *fiftieth* day after the feast of unleavened bread; *i. e.* the fifteenth of the month Nisan, and next day after the Feast of the Passover. Being celebrated seven weeks after this latter, it also obtained the name of the Feast of Weeks. It occurred about the beginning of the harvest, and seems to have been instituted as an acknowledgment of the goodness of God in giving the fruits of the earth. It also commemorated the giving of the law on Mount Sinai upon that day. The diffusion of the Holy Spirit upon the apostles upon the same day, as recorded in Acts ii., has occasioned its observance to be continued among Christians. In England it is known by the name of Whit Sunday; and in Germany by that of *Pfingsten.*

PENTELA'SMIDÆ. (Gr. πεντε, and ελασμα, *a layer.*) The family of Pedunculate Cirripeds, of which the common barnacle (*Pentelasmis crocea*) is the type. The principal organs of the body are protected by five shelly plates.

PENTE'LICAN MARBLE. *See* MARBLE.

PE'NULT, or PENU'LTIMA. (Lat. penè ultima, *almost last.*) In Grammar and Prosody, the last syllable of a word but one.

PENU'MBRA. (Lat. *pene*, almost, and *umbra*, shadow.) An imperfect shadow. The penumbra of the earth is occasioned by the apparent magnitude of the sun's disk, and is that portion of space behind the earth within which a body will be illuminated by a part only, and not by the whole of the disk. It is thus distinguished from the *umbra*, or perfect shadow, which is the conical

space within which no part of the disk is visible. Let S be the sun, E the earth, A D the orbit of the moon; and let *a* A, *a* C, *d* B, *d* D, be tangents to S and E. As soon as the moon passes the point A, a portion of the sun's disk at *a* will be intercepted, and the visible portion will become less and less until the moon reaches B, where total darkness begins. From A to B, therefore, the moon is in the penumbra. The umbra extends from B to C. When the moon passes C, it will again receive the light from the border of the solar disk at *a*, and will be in the penumbra from C to D. The whole penumbra thus forms a cone, of which the apex is at O, and the angle at the apex equal to A O D. As the obscurity evidently becomes greater in proportion as more of the solar disk is concealed, and insensibly merges into total shade, it is extremely difficult in eclipses of the moon to determine by observation the exact time at which the moon's limb passes the point B or C, and the eclipse begins or ends.

In solar eclipses those parts of the earth which are covered by the penumbra of the moon are only partially deprived of the sun's light. Let E be the moon, and A D part of the earth's orbit. To a spectator on the earth, placed between A and B, a part of the sun's disk is concealed, and the sun is partially eclipsed. The limits are calculated from the known magnitudes and positions of the sun and moon, and their respective distances from the earth. *See* ECLIPSE.

PENUMBRA. In Painting, &c., the boundary of shade and light where the one blends with the other, the gradation being almost imperceptible.

PEPERI'NO. An Italian name for a particular kind of volcanic rock, formed by the cementing together of sand, cinders, &c.

PE'PLUM. An upper garment anciently worn by the Grecian, and especially by the Athenian females: it was without sleeves, and fastened by a clasp on the arm or shoulder. The celebrated peplum of Minerva was carried every year, in the Panathenaic processions of Minerva, from the Ceramicus to the temple of Ceres, and thence to the Parthenon, where it was offered to the goddess. The antiquity of this kind of ceremony is evinced by the passage in the *Iliad* (book v.) where the Trojan women offer a similar robe.

PEPPER. *See* PIPERACEÆ, PIMENTO.

PE'PTIC, relating to digestion. *See* DYSPEPSIA.

PERAMBULATOR. (Lat. ambulo, *I walk.*) A machine for measuring distances on roads; also called *odometer* and *surveying wheel*. Various sorts of machines have been constructed for this purpose, both in ancient and modern times. One is described by Vitruvius in his work *De Architectura*, lib. x. c. 14. The machine commonly employed consists of a wheel, to which a sort of double pole is attached, carrying an apparatus of clockwork, which is set in motion by the revolution of the wheel, and shows the number of miles, furlongs, &c., passed over by an index and dial. The apparatus may be drawn along by a person on foot, or by a carriage, to which it is more usually attached. For the sake of facility in reckoning, the circumference of the measuring wheel is made equal to an aliquot part of a mile; usually half a pole, or 99 inches. (See the *Repository of Arts*, vi. 249.)

PERCE'PTION. (Lat.) In Mental Philosophy, that power, act, or state of the mind, which has a conscious reference to external objects. Various theories of perception have arisen among philosophers, differing as this reference is supposed to be more or less immediate, or as the objects to which it refers are conceived to possess an independent reality or not. These theories are designated by the terms *idealism* and *realism*; which latter is subdivided into natural or positive, and relative or negative realism. The best known system of idealism is that of Bishop Berkeley. *See* IDEALISM.

According to the scheme of negative or relative realism, all that we can know of an object is the feeling which it excites in our minds. The cause of this feeling we necessarily judge to be something external to ourselves; but what it is in itself we have no means of knowing. This is the view adopted by the great majority of philosophers, from Plato and Aristotle down to Kant and Brown.

The theory of natural realism is the one supported by Dr. Reid under the name of the *common-sense* system. This philosopher conceives the object in perception to be in some way *immediately* present to our consciousness; its qualities are not merely felt by us, but discovered *in it*. We derive a certain sensation from the whiteness or roundness of an object; but it is the object itself and not our minds that are white or round. This doctrine, which was also that of the ancient Stoics, and expressed by them in nearly the same words as those used by Reid (see Cicero, *Acad. Quæst.*), is in fact rather a statement than an explanation of the problem. It has been recently supported with great acuteness by a learned writer in the *Edin. Review*, No. 113.; to which we refer our readers for a full account of all possible theories of perception.

PERCH, in Land Measure, is the fortieth part of a rood, or equal to $30\frac{1}{4}$ square yards. Perch is also sometimes used as a denomination of long measure, when it signifies the same thing as a rod or pole, being $5\frac{1}{2}$ yards, or $16\frac{1}{2}$ feet.

PERCHERS. The name of an order of birds including the *Scansores* and *Passeres* of Cuvier. *See* INSESSORES.

PERCHLO'RIC ACID. When sulphuric acid is poured upon chlorate of potash, gaseous oxide of chlorine is evolved, and the saline matter which remains is a mixture of bisulphate of potash and perchlorate of potash; by washing it with cold water the former salt is dissolved, but the latter remains in the form of a white powder. When this is mixed with half its weight of sulphuric acid, diluted with one third of water, and heat applied, white vapours rise, which condense as a colourless liquid in the receiver. This is a solution of perchloric acid, which consists of 1 equivalent of chlorine = 36, and 7 equivalents of oxygen $(8 \times 7) = 56$; the equivalent of the perchloric acid, therefore, is $(36+56)$ 92. Perchlorate of potash requires 65 parts of water at 60° for solution.

PE'RCOIDS, *Percoidæ*. (Lat. perca, *a perch.*) The name of the tribe of Acanthopterygian fishes of which the genus *Perca* is the type.

PERCU'SSION. (Lat.) In Mechanics, the striking of one body against another, or the shock arising from the collision of two bodies. *See* COLLISION.

PERCUSSION CAPS. *See* GUN.

PERCUSSION, CENTRE OF. That point in a solid body revolving on an axis at which, if an obstacle were there applied sufficient to resist the rotation of the system, no motion would be communicated to the axis; or, which is the same thing, if the axis were not fixed the system would acquire no tendency to revolve through the shock applied at that point. The centre of percussion is in the straight line passing through the centre of gravity perpendicular to the axis; and its distance from the axis is expressed by the formula $\int r^2\, d\, m \div \int r\, d\, m$, where $d\, m$ is the element of the mass, and r the distance of $d\, m$ from the axis. *See* CENTRE.

PERCUSSION OF FLUIDS. *See* HYDRODYNAMICS.

PEREDI'OLA. (Gr. περιδέω, *I bind round.*) The membrane by which the sporules of Algaceous plants are immediately covered.

PER'ENNIALS. (Lat. perennis, *lasting throughout the year.*) In Botany, those plants whose roots remain alive more years than two, but whose stems flower and perish annually. Gardeners generally call them Herbaceous plants. They differ from annuals and biennials not only in the time of their duration; but also in this, that the two former perish as soon as they have flowered, the act of reproduction exhausting their vital energies. Notwithstanding this distinction, it is not at all times easy to say whether a plant is a perennial or not; as for instance in the *Agave Americana*, commonly called the American aloe. This plant is herbaceous, and lives for many years; but when it flowers it dies: so that in one respect it is annual, its whole life being regarded as only one season of growth; in another respect it is truly perennial. Such perennials are called by De Candolle *monocarpic*.

PERE'NNIBRANCHIATES, *Perennibranchiata*. (Lat. perennis; branchia, *gills.*) The name of that division of Batrachian reptiles including the species which preserve the external branchiæ, or branchial apertures, throughout life; as the Siren, Proteus, and Menopome.

PE'RFECT CADENCE. In Music. *See* CADENCE.

PERFECTIBI'LITY. The capability of arriving at perfection. This word, which is entirely modern, and scarcely as yet admitted in our language on classical English authority, is commonly used in reasoning on the social condition of mankind. The theory of the indefinite perfectibility of the human faculties, which constitutes the basis of many modern systems, is perhaps nowhere so plainly developed as in the Preface to the *Tableau Historique de l'Entendement Humain* of Condorcet.

PE'RFECT NUMBER. In Arithmetic, a number equal to the sum of all its divisors. Thus 6 is a perfect number, for its divisors are 1, 2, and 3; and $1 + 2 + 3 = 6$. In like manner, 28 is a perfect number, for its divisors are 1, 2, 4, 7, 14; the sum of which = 28.

In general, every number of the form $2^{n-1}(2^n - 1)$, the latter factor being a prime, is a perfect number, the sum of its divisors being equal to the number itself. The difficulty, therefore, of finding perfect numbers arises from that of finding primes of the form $2^n - 1$, which is very laborious. The only values of n yet discovered which make $2^n - 1$ a prime number are 2, 3, 5, 7, 13, 17, 19, and 31. Substituting these values of n successively in the formula of the perfect number, we shall obtain the following results: —

If $n = 2$, then $2\ (2^2 - 1) = 6$
$n = 3$, $2^2\ (2^3 - 1) = 28$
$n = 5$, $2^4\ (2^5 - 1) = 496$
$n = 7$, $2^6\ (2^7 - 1) = 8128$
$n = 13$, $2^{12}\ (2^{13} - 1) = 33550336$
$n = 17$, $2^{16}\ (2^{17} - 1) = 8589869056$
$n = 19$, $2^{18}\ (2^{19} - 1) = 137438691328$
$n = 31$, $2^{30}\ (2^{31} - 1) = 2305843008139952128$
all which are perfect numbers.

PE'RFECT TENSE. That form of the verb denoted in English by the auxiliary *have*, which designates an action finished at the time when we speak of it. Also termed the preterite tense, from Lat. præteritum, *past*.

PERFU'ME. (Fr. parfum.) A term used to denote the volatile effluvia from any body affecting the organ of smelling, or the substance emitting those effluvia. Perfumes were in general use among the ancients (see the *Quart. Rev.* vol. xxiii.); and in France, Germany, Spain, and Portugal, and even, though not to so considerable an extent, in England, they are regarded almost as necessaries. In general they are made of musk, ambergris, civet, rose and cedar woods, orange flowers, jessamines, jonquils, tuberoses, and other odoriferous flowers. Aromatic drugs, such as storax, frankincense, benzoin, cloves, &c. &c., enter into the composition of a perfume; and many perfumes are composed of aromatic herbs or leaves, as lavender, marjoram, sage, thyme, &c. &c. (See the article " Perfumery " in *Ure's Dict. of Arts, &c.*)

PERGAME'NEOUS. (Lat. pergamena, *parchment.*) In Entomology, when a part consists of a thin, tough, semitransparent substance, somewhat resembling parchment.

PE'RGULA. (Lat.) In Ancient Architecture, a sort of gallery in a house. It is used by Plautus to signify a balcony, in which the courtezans placed themselves to catch the attention of passengers. By Winckelman it is thought to be an arbour in a garden, or a terrace overhanging one.

PERIA'NTHIUM. (Gr. περι, *around*, and ανθος, *a flower.*) A calyx and corolla, the limits of which are undefined, so that they cannot be satisfactorily distinguished from each other; as in many Monocotyledonous plants.

PERI'BOLOS. (Gr. περι, and βαλλω, *I cast.*) In Architecture, a court or enclosure entirely round a temple, surrounded by a wall. One of the most extraordinary examples of a peribolos is at Palmyra, where the great temple is surrounded by a wall with two rows of interior columns, each side whereof is from 700 to 800 feet long.

PERICARDI'TIS. Inflammation of the pericardium. It is of the same origin as

PERICA'RDIUM. (Gr. περι, *about;* καρδια, *the heart.*) The membranous sac which surrounds the heart.

PERICA'RPIUM. (Gr. περι, and καρπος, *fruit.*) Every part of a ripe fruit on the outer side of the placenta.

PERICHŒ'TIAL. (Gr. περι, and χαιτη, *a bristle.*) The leaves situated at the base of the setæ of mosses.

PERI'COPE. (Gr. περι, and κοπτω, *I cut; something cut out, an extract.*) A word used by theologians to signify a passage of the Bible extracted for the purpose of reading in the communion service and other portions of the ritual; or as a text for a sermon or homily.

PERICRA'NIUM. (Gr. περι, and κρανιον, *the skull.*) The membrane of the bones of the skull.

PE'RIDOT. In Mineralogy, the prismatic chrysolite.

PE'RIDROME. (Gr. περι, and δρομος, *a course.*) In Ancient Architecture, the space in a peripteral temple between the walls of the cell and the columns. It is a term that may be applied to any gallery of communication round an edifice.

PE'RIGEE. (Gr. περι, and γη, *the earth.*) In Astronomy, that point of the moon's orbit which is nearest to the earth. Anciently the term *perigee* was applied to the orbits of the sun and planets, as well as the moon, because they were supposed to circulate round the earth. Since the true centre of motion has been discovered, the term *perihelion* is used to denote the corresponding points.

PERIGO'NIUM. (Gr. περι, and γινομαι, *I grow.*) A synonym of the word perianth.

PERIGY'NIUM. (Gr. περι, and γυνη, *a female.*) The urceolate body formed in the genus *Carex* by two bracteæ, which become confluent at their edges, and enclose the pistillum, leaving a passage for the stigmata at their apex. Also used occasionally to denote that organ commonly called the disk.

PERI'GYNOUS. A term applied to stamens which originate from the sides of a calyx.

PERIHE'LION. (Gr. περι, and ἡλιος, *the sun.*) In Astronomy, the point in the orbit of a planet or comet which is nearest the sun. It is the extremity of the major axis of the orbit nearest to that focus in which the sun is placed; and its position, or longitude, is one of the elements by which the orbit is determined. *See* PLANET.

PERI'METER. (Gr. περι, and μετρον, *measure.*) In Geometry, the circuit or boundary of any plane figure. In round figures it is equivalent to circumference, or periphery; but the term is more frequently applied to figures bounded by straight lines.

PE'RIOD (Gr. περιοδος), in Astronomy and Chronology, denotes an interval of time at the end of which the same phenomenon again takes place. The period of a planet is the time in which it performs a revolution in its orbit. For chronological periods, see CYCLE. The term is also used in arithmetic, to denote the recurrence of a series of digits or numbers in the same order, as in circulating decimal fractions.

PERIOD, or SENTENCE, in Rhetoric, has been defined "a passage, *i.e.* series of words, developed in properly connected parts." In a stricter sense, a period is a sentence so framed that the grammatical construction will not admit a close, and the meaning remains suspended until the end of it. A sentence in which the sense would permit of a stop before its completion is, in this sense, not a period. The Greek and Latin languages were much more periodic than most modern tongues; that is, they admitted of the construction of sentences so that a single grammatical connection should run through a great series of words, while a similar series, in a modern language, would be so arranged as to form several distinct grammatical wholes.

PERIOD, THE JULIAN. In Chronology. *See* JULIAN PERIOD.

PERIO'DIC ACID. An acid analogous in composition to the *perchloric*, consisting of 1 equivalent of iodine + 7 equivalents of oxygen.

PERIO'DICALS. In Literature, strictly publications continued in numbers, appearing at regular intervals. But papers of the same description appearing at uncertain intervals (especially in Germany), are often comprehended under this general name. The first periodical in the character of a review was the *Journal des Savans*, begun in 1663.

PERIŒ'CI, or PERIŒCIANS (Gr. περι, *about*, and οικεω, *I dwell*), in Geography, is used to denote those inhabitants of the globe who live under the same parallel of latitude, but on opposite meridians; that is, in places which have the same latitude, but differ in longitude by 180°. They have their spring, summer, winter, and autumn in the same months of the year; but when it is noon with the one it is midnight with the other.

PERIO'STEUM. (Gr. περι, and οστεον, *a bone.*) The membrane which invests the bones. It is of a fibrous texture, and vascular.

PERIO'STRACUM. (Gr. περι, and οστρακον, *a shell.*) The layer of animal substance, or cuticle, which covers the outer surface of shells, and which the French conchologists term *drap marin*.

PERIPATE'TICS. That school of ancient philosophers which derived its origin from Aristotle. The name was given them from the Gr. περιπατοι or *walks* in the Lyceum, the scene of Aristotle's instruction. (For the doctrines of the Peripatetics, see ARISTOTELIAN PHILOSOPHY.) The immediate successors of Aristotle in the peripatetic doctrine were Theophrastus, Eudemus the Rhodian (from whom is derived the title of the Eudemian Ethics), Dicæarchus of Messana, Aristoxenus of Tarentum, and Strato of Lampsacus; among the later Peripatetics are preserved the names of Glycon of Troas, Hieronymus of Rhodes, &c. It would be unreasonable to expect that so elaborate a system as that of Aristotle should have received any important addition to its leading doctrines at the hands of his followers. They contented themselves either with defending and interpreting their master's doctrines, or with applying his method to the explanation of natural philosophy. Under their hands his system seems to have degenerated into a species of empirical materialism, a scheme as widely at variance with his genuine doctrines, as was the dry scholastic formalism which in the dark ages passed for the philosophy of Aristotle. (For notices of the later Peripatetics, see Cicero, *Acad. Quæst.*, and *De Finibus*, c. 5.; Lactant. *De Irâ Dei*, c. 10.; Plutarch, *De Solertiâ*, &c.) The Peripatetic school produced no men of note after its great founder, which is attributable to the current of free speculation being shackled by the authority of Aristotle, whose dogmas it was content to illustrate without daring ever to impugn; and in this respect its spirit was remarkably contrasted with the scepticism of the new Academy. (See *Ritter's Hist. of Anc. Philosophy*, book ix. ch. i.)

PERIPETEI'A, or REVOLUTION. (Gr. περιπετεια.) According to Aristotle, in his *Art of Poetry*, a necessary condition or circumstance of the drama; being a change of fortune, from happiness to misery, or the reverse, which takes place in the situation of the principal personage. *See* CATASTROPHE, DRAMA.

PERI'PHERY. (Gr. περι, and φερω, *I carry.*) In Geometry, the circumference of a circle or ellipse, or of any other curvilinear figure.

PERI'PHRASIS, or CIRCUMLOCUTION. (Gr. περι, and φραζω, *I speak.*) In Rhetoric, the use of several words to express the sense of one, or of a more involved and prolix form of expression to convey a meaning which might be adequately denoted by a shorter phrase.

PE'RIPLUS. (Gr. περὶ, and πλοῦς, *sailing.*) A circumnavigation. The word is only used as the title of some fragments which remain to us of narratives of voyages of the classical ancients. The *Periplus* of Hanno is a Greek translation (real or supposititious) of an inscription said to have been erected at Carthage in memory of a voyage along the western coast of Africa, respecting which much discussion has arisen among modern geographers. The date of this voyage is uncertain, but generally fixed by conjecture at 400 or 500 years before Christ. The *Periplus* of Scylax, which is supposed to belong to the age of Augustus, contains a succinct account of some journeys along the coasts of Europe and Asia. Two works bearing the same title pass under the name of Arrian, who wrote in the second century after Christ; the first contains a description of the Euxine, the second of the Erythræan Sea (Persian Gulf).

PERIPNEU'MONY. (Gr. περι, and πνεω, *I breathe.*) Inflammation of the lungs. *See* PNEUMONIA.

PERI'PTERY, *Peripteral.* (Gr. περι, and πτερον, *a wing.*) In Architecture, a building surrounded with a wing, aisle, or passage. The word *peripteral* characterizes one of the species of Greek temples, in which the cell is surrounded by a single row of columns, to distinguish it from the word *dipteral*, which designates a temple with two ranks of columns.

PE'RIS, in the Persian Mythology, are a class of imaginary beings closely allied to the elves or fairies of more northern latitudes, supposed to be the descendants of the fallen angels, and excluded from Paradise till they have made atonement for their sins. (See Moore's beautiful poem, "Paradise and the Peri," in *Lalla Rookh.*)

PERI'SCII. (Gr. περι, and σκια, *shadow.*) A name applied by the ancient geographers to the inhabitants within the arctic and antarctic circles, because, as the sun at certain times of the year does not set to them in the course of his diurnal revolution, their shadows describe an entire circumference.

PE'RISPERM. (Gr. περι, and σπερμα, *a seed.*) A term used by some to denote the testa, and by others the albumen of a seed.

PERISTA'LTIC. (Gr. περιστελλω, *I contract.*) A term applied to the peculiar motion of the intestines, by which their contents are gradually propelled from one end of the canal to the other.

PE'RISTOMES, *Peristomidæ.* (Gr. περι, and στομα, *a mouth.*) The name of a family of Pectinibranchiate Gastropods, including those species in which the shells have the margin of the aperture or mouth unbroken and continuous.

PE'RISTYLIUM. (Gr. περι, and στυλος, *a column.*) In Architecture, a court, square, or cloister, with columns on three sides: hence improperly so called. In peristylia with columns on each of the four sides, that towards the south was frequently higher than the rest. This species was called a Rhodian peristylium.

PERITHE'RIDES. (Gr.) In Architecture. *See* ANCONES.

PERITONÆ'UM. (Gr. περιτεινω, *I extend round.*) The membrane which envelops the abdominal viscera, and lines the cavity of the abdomen. Hence also *peritonitis*, or inflammation of the peritoneal membrane.

PERITRO'CHIUM. (Gr. περιτροχεω, *I run about.*) In Mechanics, a wheel or circular frame of wood, fixed upon a cylinder or axle, round which a rope is wound; and the wheel and cylinder being moveable about a common axis, a power applied to the wheel will raise a weight attached to the rope with so much the greater advantage as the circumference of the wheel is greater than that of the cylinder. This mechanical power is called the *axis in peritrochio*; the windlass and capstan are constructed on the same principle.

PE'RJURY (Lat. pejero), in Law, is a wilful false oath taken in a court of justice, by a witness lawfully required to depose the truth in a matter of some consequence to the point in question. A false oath, therefore, taken before no court, or before a court incompetent to try the issue in question, does not constitute the offence of perjury. Perjury is a misdemeanor at common law, and by several statutes punishable by fine and imprisonment, and by transportation for a term not exceeding seven years.

PERKUNOS. One of the chief divinities of ancient Prussia, who, together with Rikollos and Potrimpos, formed the sacred Trinity of the Slavonic and the adjoining nations. He was regarded as the god of the elements; and his worship extended even to Russia, Poland, Bohemia, where there were numerous temples erected to his honour. (See *Grimm's Deutsche Mythologie.*)

PE'RMIT. An order or written permission from an officer of the customs, authorizing the removal of goods subject to excise duties from one place to another.

PERMUTA'TION, in Algebra, denotes the arrangement of any determinate number of things or letters in all possible orders one after the other. For example, two letters, *a b*, give the two permutations *a b* and *b a*; and three letters, *a b c*, give the six permutations *a b c*, *a c b*, *b a c*, *b c a*, *c a b*, *c b a*. *Permutation* is effected by placing the letters in all possible orders, so that all the letters enter into each result, and each enters into it only once; and is therefore distinguished from *combination*, which implies that the arrangements are so made that any two of them differ in respect of one at least of the letters which enter into the results, without regard to the order of the arrangement.

To find the number of permutations that can be made upon any number of letters n, taken together, we may reason in this way: — Suppose the total number of permutations that can be made of $n-1$ letters to be known, and let it be designated by Q. Let us consider one of the given letters, f, by itself, and suppose it to be placed on the right of each of the Q permutations given by the other $n-1$ letters; there will result Q permutations of n letters, each ending with f. But as each of the n letters may be considered separately in the same manner as f, it follows that the total number of permutations of the n letters is equal to $Q \times n$. Let $n = 2$; Q then denotes the number of permutations of one letter; whence $Q = 1$, and $Q \times n = 1 \times 2$. Let $n = 3$; Q then denotes the number of permutations of two letters, which is just found equal to 1×2. Therefore $Q \times n = 1 \times 2 \times 3$. Let $n = 4$; Q then denotes the number of permutations that can be made on three letters, or $1 \times 2 \times 3$. Therefore $Q \times n = 1 \times 2 \times 3 \times 4$.

In general, the number of permutations that can be made upon n letters, taken together, is expressed by the continued product

$$1 \times 2 \times 3 \times \ldots . (n-1) \times n.$$

For example, the number of changes that can be rung upon twelve bells is $1 \times 2 \times 3 \times 4 \times 5 \times 6 \times 7 \times 8 \times 9 \times 10 \times 11 \times 12 = 479001600$.

PERNIO. *See* CHILBLAIN.

PERORA'TION. (Lat. per, and os, *mouth.*) The concluding part of an oration, in which either the arguments and representations of the speech are briefly recapitulated, or a short and comprehensive conclusion deduced from them, or a brief appeal made to the sentiments or passions of the audience.

PERO'XIDE. The highest degree of oxidizement of which a metal or other substance is susceptible without becoming an acid.

PERPENDI'CULAR. In Geometry, a straight line is said to be perpendicular to another straight line when the adjacent angles formed by their intersection are equal, and, consequently, each is a right angle. A straight line is perpendicular to a curve at a given point when it is perpendicular to the tangent to the curve at that point. In this case the perpendicular is usually called a *normal* to the curve. (*See* NORMAL.) A straight line is perpendicular to a plane when it is at right angles with every straight line in the plane passing through the point of intersection. A plane is perpendicular to a plane when any straight line in the first which is perpendicular to the common intersection of the two planes is also perpendicular to the second plane.

PERPETUAL MOTION. In Mechanics, a machine which, when set in motion, would continue to move for ever, or at least until destroyed by the friction of its parts, without the aid of any exterior cause. The discovery of the perpetual motion has always been a celebrated problem in mechanics, on which many ingenious, though in general ill-instructed, persons have consumed their time; but all the labour bestowed on it has proved abortive. In fact the impossibility of its existence has been so fully demonstrated from the known laws of matter, that it is rather an insult than a praise to say of any one that he has occupied himself with the research. Nevertheless, the pursuit of the chimera has been the cause of many useful inventions.

In speaking of the perpetual motion, it is to be understood that from among the forces by which motion may be produced we are to exclude not only air and water, but other natural agents, as heat, atmospheric changes, &c. The only admissible agents are the inertia of matter, and its attractive forces, which may all be considered of the same kind as gravitation.

It is an admitted principle in philosophy that action and reaction are equal; and that when motion is communicated from one body to another, the first loses just as much as is gained by the second. But every moving body is continually retarded by two passive forces, the resistance of the air and friction. In order, therefore, that motion may be continued without diminution, one of two things is necessary, — either that it be maintained by an exterior force (in which case it would cease to be what we understand by a perpetual motion); or that the resistance of the air and friction be annihilated, which is physically impossible. The motion cannot be perpetuated till these retarding forces are compensated, and they can only be compensated by an exterior force; for the force communicated to any body cannot be greater than the generating force, and this is only sufficient to continue the same quantity of motion when there is no

resistance. To find the perpetual motion is therefore a proposition equivalent to this,—to find a force (either an attractive force like that of gravitation or magnetism, or an elastic force, that of a spring for example) greater than itself.

But it may be argued that by some arrangement or combination of mechanical powers a force may be gained equal to that which is lost in overcoming friction and atmospheric resistance. This notion at first mention appears plausible, and is in fact that by which most speculators have been led astray. It is, however, entirely erroneous; for by no multiplication of forces or powers by mechanical agents can the quantity of motion be increased. Whatever is gained in power is lost in time; the quantity of motion transmitted by the machine remains unaltered.

Although the perpetual motion has been demonstrated again and again to be impossible on any known principle of mechanics, projectors have not thereby been deterred from the pursuit. In 1775 the Academy of Sciences at Paris resolved not to consider or admit into their Memoirs any future proposal for the discovery of the perpetual motion; yet such appears to be the seductive nature of the subject that innumerable schemes, designs, and projects for accomplishing it have since been, and even to the present time continue to be, put forward; and there are very recent instances of men of no common attainments and reputation, and well versed moreover in the principles of mechanical science, who have been deceived by the ingenious frauds of charlatans and impostors into a belief of its actual discovery. (Montucla, *Hist. des Math.* tome iii. p. 813.; *Repertory of Arts*, vols. vii. and xiv.; *London Journal of Arts*, May, 1827; Airy, *Trans. of the Cambridge Phil. Soc.* vol. iii. part. 2.; Poppe, *Wunder der Mechanik*, 1832; and various papers in the earlier volumes of the *Memoires de l'Academie des Sciences*, and the *Philosophical Transactions*.)

PERPETUI'TY, in the doctrine of Annuities, is the sum of money which will purchase a certain annuity to continue for ever. This is equal to the product of the annuity into the number of years in which the simple interest of any sum will equal the principal. For example, if the rate of interest be 4 per cent., the simple interest of any sum will amount to a sum equal to the principal in twenty-five years. The value, therefore, of the perpetuity of 100*l.* per annum is 2500*l.* The number of years is equal to unit divided by the rate of interest, or 100 divided by the rate per cent.

PE'RRY. (Lat. pirum, *a pear.*) A fermented liquor made from pears, in the same manner as cider from apples. The pears best fitted for producing perry are exceedingly harsh and tart; but it is itself pleasant and wholesome.

PERSECU'TIONS. The name by which several periods in the history of the Christian church are historically distinguished. Of these by far the most sanguinary occurred in the first centuries of the Christian era, and originated in the desire of the Gentile nations to extirpate the followers of the Christian faith. On the accession of Constantine to the throne of the Western world, these Gentile persecutions ceased; and the subsequent history of the church is disfigured by persecutions raised by the more powerful against the weaker of the Christian sects.

PERSEUS. Son of Jupiter and Danae, one of the most distinguished heroes of the Grecian mythology. His history is too well known to be recapitulated here. His chief exploit was the conquest of *Medusa* (which see).

PERSEUS. One of the forty-eight ancient constellations, situated in the northern hemisphere.

PERSEVE'RANCE, or FINAL PERSEVERANCE. In Theology, the continuance of the elect in a state of grace to the end of their lives, which, according to some theologians, must always be the case with him who has once been truly called into such a state. Since God is represented as the image of perfection and immutability in himself, so, it is argued, having once begun the preparation of a human being for a blessed eternity, he will not leave his work unfinished; but the person concerned must necessarily persevere to the end in a state of acceptance, under the absolute decree of which he was originally elected unto life.

PE'RSIAN WHEEL. In Mechanics, a contrivance for raising water to some height above the level of a stream. In the rim of a wheel turned by the stream a number of strong pins are fixed, from which buckets are suspended. As the wheel turns, the buckets on one side go down into the stream, where they are filled, and return up full on the other side till they reach the top. Here an obstacle is placed in such a position that the buckets successively strike against it and are overset, and the water emptied into a trough. As the water can never be raised by this means higher than the diameter of the wheel, it is obvious that this rude machine is capable of only a very limited application. Sometimes the wheel is made to raise the water only to the height of the axis. In this case, instead of buckets, the spokes are made hollow, and bent into such a form that when they dip into the water it runs into them, and is thus conveyed to a box on the axle, whence it is emptied into a cistern. Such wheels are in common use on the banks of the Nile, and elsewhere.

PERSISTENCE (Lat. per, *through;* sisto, *I remain*), in Optics, signifies the duration of the impression of light on the retina after the luminous object has disappeared. Thus, if a lighted torch is whirled round rapidly, a continuous circle of light is seen. A great number of illusions of the same kind, as the augmentation of the apparent volume of a musical chord when in vibration, the luminous train accompanying a falling meteor, &c., are explained by this property of vision; and it has been ingeniously applied by Professor Wheatstone to measure the velocity of electric light.

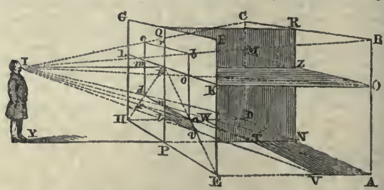
PERSON. *See* GRAMMAR.

PE'RSONAL PROPERTY, according to the division recognized by our law, is best defined negatively, as including every thing which may be made the subject of property, and which is not legally considered as appertaining to land. The original distinction was undoubtedly between things moveable and immoveable. But, on the one hand, a personal interest may be acquired in things immoveable, *i. e.* in land by lease for years (chattels real); while, on the other hand, some things not affixed to the soil and some bare rights and privileges are considered as freehold. The distinction, therefore, is scarcely maintained with philosophical accuracy, although we may still consider that every thing which is of a freehold nature is either obviously or constructively connected with the enjoyment of land, or, in technical language, *savours of the realty;* while every thing wholly unconnected with land falls under the denomination of chattels personal. The term *chattel* is derived from the barbarous Latin word *catallum*.

Besides chattels real, already adverted to, personal property is said to be either *in possession* or *in action*. The first class of objects includes every thing comprehended under goods and chattels, ready money and stock, or such animals as are the subjects of property: the second class are legally termed *choses* or things in *action*, and are defined to be things to which a man has a bare right without any occupation, the possession whereof may be recovered by a suit or action at law. Of this class, therefore, are all debts, and the securities for them, unless these securities attach on land. Sums of money due on bond, on bills of exchange, and promissory notes, property in the funds, all fall within this comprehensive class, which, originally so trifling as to be hardly noticed in early jurisprudence, now comprehends by far the greater part in value of the moveable property of our commercial community.

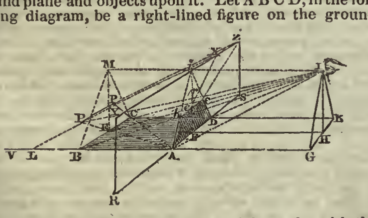
PERSONIFICA'TION, or PROSOPOPŒIA. In Rhetoric and Composition, a figure of speech, being a species of metaphor (*see* METAPHOR), by which inanimate objects, or abstract notions, are represented as endued with life and action: sometimes by being addressed as living agents (*see* APOSTROPHE); at other times, by being coupled with attributes which belong only to living agents.

PERSPECTIVE. (Lat. perspicio, *I look through.*) In the Fine Arts, the art of delineating on a given transparent plane or superficies objects as they appear to an eye placed at a given height and distance. From the definition, it is evident that to delineate the true appearance of an object on a plane surface, it becomes necessary to know the laws according to which the apparent linear dimensions of an object increase or decrease; and they are these generally:—1. The visual angle, or the apparent magnitude of a line, will be less the greater the distance, and the converse; 2. It will be less the more obliquely a line is viewed; 3. The law of diminution will be nearly in proportion to the obliquity and distance conjointly. In the following diagram, let the eye



of the spectator be at I, and let E F G H be the plane on which the appearance of objects is observed. This is called the *perspective plane*, or *plane of the picture*. Now the appearance of every object to be delineated will vary according to the plane in which it stands, considered with respect to the perspective plane; hence the particular situations of object planes are the main points for consideration. It is manifest that any plane passing through the eye can only be seen on the perspective

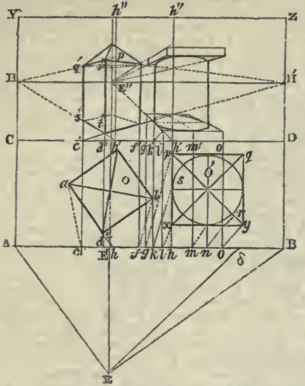
plane as a line; for the eye, having neither elevation above nor depression below such plane, can see no part of its surface, its edge being all that is visible to the eye. Of such planes two are of primary importance in perspective; viz. the *horizontal plane*, O K L M, parallel to the horizon; and the *vertical plane*, Q P R N, perpendicular to the last. The first intersects the perspective plane in the line L K, called the *horizontal line;* and the last in the line Q P, called the *vertical line.* Planes not passing through the eye must have a *direct* or an *oblique* situation relative thereto. If the former, it must be parallel to the perspective plane, which is supposed to be placed *directly* before the eye; thus, the plane A B C D is a direct one, and parallel to the perspective plane G E. Of the planes situated obliquely to the eye, the most considerable is A E H D, which is called the *ground plane*, and is parallel to that of the horizon. From the foregoing observations, then, it appears that objects in the surfaces of the horizontal and vertical planes cannot be seen by the eye at I; and therefore cannot be represented on the perspective plane. If O B be an object in the direct plane, and from the extreme points O and B the visual rays O I, B I be drawn to the eye at I, they will pass through the perspective plane in the points *o* and *b*, and by joining them the right line *o b* will be the representation of the line or object O B on the perspective plane. In like manner the representation of O A is *o a*, and *b r* and *a n* will be the representation of B R and A N, and consequently *r b a n* of R B A N, &c. &c. So all lines parallel to A B or C D in the object plane will have their perspective lines parallel to *a b* and *c d* in the picture on the perspective plane; and however the object plane A C may be divided, their representations on the perspective plane or planes of the picture will divide that in a similar manner. Any point B in a direct plane has the same ratio of distance from the horizontal and vertical planes, as its perspective has from the horizontal and vertical planes, viz. that of the distances of the planes from the eye, from the nature of similar triangles: hence the forms of objects on the perspective plane, when they are presented in a direct view, may be drawn with facility. The last species of plane whereon it is supposed we may view the natural object is that of the ground itself, as A D H E, above which the eye has more or less an elevation; as *i* P, equal to I Y. This is hence called the *ground plane*, and its intersection, H E, with the perspective plane is called the *ground line.* It is more important than all others, as being the common table, as it were, on which every thing is placed. In respect to this horizontal plane, we have seen that the two remote angles thereof, A and D, are represented by *a* and *d* in the perspective plane; the other two angles, E and H, are in the same plane also, as being common to both; therefore, by drawing the lines *a* E and *d* H, there will be formed the figure E and H on the perspective plane, which will be the correct perspective appearance of the ground plane A D H E. Thus, *a* E is the perspective of A E, *n* P of N P, and *d* H of D H; and lines that are parallel in the ground plane and perpendicular to the perspective plane are not so in their perspective picture, but converge to a point *i*, called the *point of sight*, in the perspective plane, because exactly opposite to the eye, or the point in which a perpendicular from the eye falls on the plane. In the ground plane draw V W parallel to A D; its perspective *v w* will be parallel to *a d* in the picture, and *a d w v* will be the perspective of the part A D W V in the original plane. We shall now proceed to a demonstration of what relates to forming the perspective appearance or picture of the ground plane and objects upon it. Let A B C D, in the following diagram, be a right-lined figure on the ground



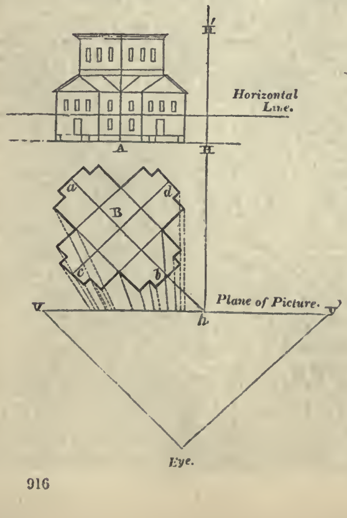
plane V G K C, contiguous to and at right angles with the perspective plane Y Z S R. F H is the distance of the plane, and H I the height of the eye at I. H E is parallel to G B or C K, and bisects A D and B C in the points F and E. On the point E raise the perpendicular E M, equal to H I, and draw the lines B M, C M, G I, and K I. Draw the visual lines I A, I B, and I M, which is called the *principal ray*, and is perpendicular to the perspective plane in the point *i*. Now it is evident that the plane I G B M intersects the perspective plane in the line A *i*, and the ray B I, being in the said plane G M, must intersect the line A *i* in some point *b*, which is therefore the perspective of the point B: hence A *b* is the perspective of the line A B. Also, as the plane I K C M intersects the perspective plane R Z in the line D *i*, and the ray I C is in that plane, and intersects the line *i* D in the point *c*, that point will be the perspective of the point C, and D *c* that of the line D C. Joining the points *b c*, the line *b c* will be the perspective of the line B C in the ground plane. Let A B equal D C, then B C will be parallel to A D; and as in this case A *b* is equal to D *c*, *b c* will be parallel to A D also. From this it is manifest *that all right lines, as* B C *in the ground plane, which are parallel to the ground line* A D, *will also be parallel to the same in their representations on the perspective plane.* It is moreover evident *that the representations* A *b*, F *e*, D *c*, *of all lines* A B, F E, D C, *perpendicular to the ground line* A D, *converge or tend to the point of sight i in the perspective plane.* If the line A B be carried out infinitely in the direction of V, then, supposing the point B to move along that line continually, the visual ray B I will keep rising on the plane I G B M towards I M, making the angle B I M less and less, till the point B being at an infinite distance the ray I B will coincide with I M, and consequently the line A *i* will be the perspective of A B continued infinitely. So D *i* will be the representation of the line D C continued infinitely. Hence *the triangle* A *i* D *will, on the perspective plane, be the true representation of the plane* A B C D *carried out infinitely on the plane of the horizon.* Hence, also, the line Y *i* Z is the perspective of the horizon or boundary of the sight at an infinite distance; and therefore all objects on the plane of the horizon will, in their representations, be seen to rise from the ground line towards the point of sight, and lessen in appearance as they grow more distant, till at last they vanish in the horizontal line Y Z. We now come to lines which lie oblique to or make an angle with the ground line A D, or any other parallel to it. Make A L equal to A G or I *i*, and draw A *p* to make any angle *p* A R or *p* A D with the base A D, acute or obtuse. Then in the horizontal line Y Z take *i* X, equal to L *p*, and draw *p* X and *i* X; the plane I X *p* A will intersect the perspective plane in the line A X. Draw the visual ray I *p*, which, being in the plane I X *p* A, must go through the perspective plane somewhere in the line A X, which suppose at *r*. Then is the point *r* the perspective of *p;* and since the point *p* is supposed to pass from A to *p*, in describing the line A *p* its perspective *r* will move in the plane A Z from A to *r*, and describe the line A *r*, which therefore will be the representation of the line A *p*. If A *p* be carried out infinitely, and the point *p* supposed to move constantly therein, its representation *r* will appear to move towards X, till at length the point *p* being at an infinite distance, *r* arrives at and coincides with X in the horizontal line. A X is therefore the representation of the line A *p* infinitely continued; and X is called the *accidental point*, to which the representations of all lines parallel to A *p* tend. Let L P be taken equal to A L, and *i* Z equal to *i* I; then, joining A P and *i* Z, the triangles A P L and *i* Z I are equal. Then will the plane *i* A P Z intersect the perspective plane in the line A Z, which will be the representation of the line A P carried to an infinite distance. But since A L is equal to L P, and L P is parallel to A D, therefore A P is the diagonal of a square, and contains an angle D A P of forty-five degrees with the ground line A D; hence the point of distance Z is that to which all rays parallel to A P tend in the perspective plane. Let A B equal A D; then is A B C D a geometrical square, and its diagonal A C, whereof the representation is A *c;* and the point *c* is therefore that in which the perspective diagonal A Z intersects the ray or radial line *i* D. Make *i* Y equal *i* Z, or *i* I, and join D Y, and it will be the perspective diagonal of D B (the other diagonal of the square A C) infinitely continued, and D *b* the representation of the diagonal D B, determined by the intersection of the lines D Y and A *i*, as before. Thus it is demonstrated that A *b c* D on the perspective plane A S Z Y is the true picture or perspective representation of the original square A B C D on the ground plane, as required.

From the above principles are deduced the common rules of perspective, of which we shall give two or three examples. A B C D is a ground plane, whereon are seated the objects O and O′. The line A B is the plan of the plane of the picture, or its intersection with the ground plane; and C D Y Z is the plane of the picture, or the perspective plane, as we have before called it. It will be observed that one of the objects, O, lies obliquely towards the perspective plane, and the other is parallel to it or direct. We will first deal with the former. From the station of the eye, E, parallel to *a e* and *e b*, two of the sides of the object, draw the lines E A and E B, cutting the plane of the picture in A and B. Then will A be the vanishing point of all lines parallel to *a e*, as will be B of all lines parallel to *e b*. E′ is the place of the eye at the intersection of the ground plane with the picture, being a perpendicular from A B to E′. If H H′ be the horizontal line, then H E″, equal to A E′, is the place of the eye on the perspective plane. From the different points of the object *a e b* draw towards E as a centre the visual rays *a c*, *e d*, *b f*, intersecting A B in

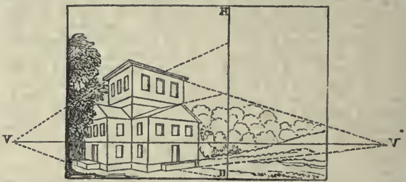
c, d, and f; and from them continue upwards indefinitely the verticals $c\,c'$, $d\,d'$, $f\,f'$, which will be the boundaries of



the sides $a\,e$ and $e\,b$ respectively. On the plan continue one of the sides $a\,e$ till it intersects the picture in h, and make C h' on the perspective plane equal to A h on the plan; and draw the vertical $h'\,h''$, which will be the *line of heights* on which they are to be set out. Then, if $h'\,p$ be the height of the object O, lines drawn from h' and p to the vanishing point H will intersect the verticals in q and r and s' and t'. In like manner, lines drawn from t' and r' towards the vanishing point H will give the representation of the other side. Lines drawn in opposite directions at the top of the figure (dotted in the diagram) will enable the draftsman to draw diagonals from whose intersection a vertical may be raised for crowning the object with a pyramid or other figure. In respect of the object O′, which on the plan is a square circumscribing a circle, the object being direct or parallel to the picture, all those lines parallel to it will be horizontal, and the vanishing point of the returning sides $p\,x$, $q\,y$ will be found in E′ (or E″ in the picture), which, as in the former case, is found by a line from E parallel to those sides intersecting the picture. Similarly, a line from E parallel to $x\,q$, intersecting the picture in δ, will be the vanishing point of all diagonals of a square in that direction. The visual rays tending to E, shown at $g\,k\,l$, &c., are to be transferred to the picture by verticals as before. In this object $h\,h'\,h''$ will be seen to be the line of heights, on which all heights are to be set out. The perspective extent of a circle is easily obtained by lines bounding its convexity, transferred by the visual rays $s\,k\,r\,n$ to the picture, which, aided by the diameters, will give the form required. To give the reader a general notion of the common mode of proceeding in perspective representations of buildings, we present the following diagrams. B is the plan of a building to be thrown into



perspective, inclined to the plane of the picture at any angle $v\,h\,a$. The vanishing points of all lines parallel to $a\,b$ are found by a line from the eye parallel to $a\,b$, cutting the picture in V. Similarly, V′ is found to be the vanishing point of all lines parallel to $c\,d$. If $a\,b$ be continued to h, it gives the place of the line H H′, whereon the heights of the different parts of the elevation A may be set according to their several altitudes. The place of the horizontal line is chosen so as to afford the most agreeable representation of the object; its height depending, of course, on that at which the eye would most probably be placed, or might be supposed to be. The visual rays to the eyes are shown by the dotted lines. Having thus prepared the geometrical plan and elevation of the object, the plane of the picture is set out as under; and the reader must observe that the whole extent of it hori-



zontally must not take in an angle of more than sixty degrees, that being as great as the eye can take in without turning the head, though in internal views a greater extent is generally tolerated. It is to be observed that in this diagram the representation, for the sake of greater distinctness, is doubled in dimensions from the plan. The place of H H′ is transferred to the picture, and the height carried down from it to the vertical lines, whose places have been found by the visual rays above mentioned. The vanishing points V and V′ are transferred to the horizontal line V V′, and the horizontal lines in the sides tend thereto. It is obvious that a similar process enables the draftsman to make internal representations, the principles whereon they are conducted being precisely the same. It is needless to expatiate on the importance of perspective to the painter; and though Fresnoy has advised that "the compasses should be rather in his eyes than in his hands," it is clear that without a knowledge of its laws he can never hope to succeed.

That perspective was unknown to the ancients, as some have supposed, is a mistake. What has led to such an error has been, perhaps, the violation of its rules in basso relievo, and particularly in those on the Trajan column, where attention to them would have been impossible, if not improper. Another ground for the supposition is the ignorance of perspective displayed in the paintings of Herculaneum and Pompeii. But such examples are no proof. How many painters of our own days, some of them even possessing a certain sort of reputation, are sadly ignorant upon the subject. The truth is, that the ancients were not only eminent for their success in painting walls with architectural subjects, but they were also known to have required the practice of this branch of the arts in the decorations of their theatres. To such a point of perfection was it carried, if we may rely on Pliny, that in the decorations of the theatre of Claudius Pulcher the imitations were so striking that the birds attempted to alight on the tiles of the roofs. This probably, however, is but a figurative description of the work, and that it was so intended; for otherwise it would be drawing rather too largely on our credulity. Vitruvius tells us, in the Preface to his 7th Book, that perspective was well understood at a very early period. His words are, "Agathasius, at the time when Æschylus taught at Athens the rules of tragic poetry, was the first who contrived scenery, upon which subject he left a treatise. This led Democritus and Anaxagoras, who wrote thereon, to explain how the points of sight and distance ought to guide the lines, as in nature, to a centre; so that, by means of pictorial deception, the real appearances of buildings appear on the scene, which, painted on a flat vertical surface, seem nevertheless to advance and recede." Neither was the practice of perspective confined to the representations just mentioned. Its knowledge was considered equally necessary in pictures. The painter Pamphilus, whose celebrated school of design was at Sicyon, taught perspective publicly, and carried his opinions on this head to such an extent that he considered no perfect painting could be executed without a knowledge of geometry. "Omnibus letteris eruditus præcipuè arithmeticæ et geometriæ, sine quibus negabat artem perfici posse."

The earliest authors on the subject whose works have reached us are Bartolomeo Bramantino of Milan, whose work, *Regole di Prospettiva e Misure delle Antichità di Lombardia*, appeared in 1440; and Pietro del Borgo, who, as he died in 1443, probably wrote earlier. Baltazzare

Peruzzi, improving on the methods of Pietro, whom he had carefully studied, very considerably advanced the science. Guido Ubaldi followed him; and, publishing his work at Pesaro, in 1600, established its principles on a basis which left little to be done by our countryman Dr. Brook Taylor, the first Englishman who wrote scientifically on the subject. The works on the subject are in every language very abundant; but, in our own, the work of Thomas Malton, published in folio, London, 1776, entitled *A complete Treatise on Perspective, in Theory and Practice, on the Principles of Dr. Brook Taylor*, is the most valuable to the student, and should be in the hands of every one who has a desire to be thoroughly acquainted with the subject.

PERSPECTIVE, AERIAL. *See* AERIAL.

PERSPIRA'TION. (Lat. perspiratio.) The vapour secreted by the ramification of the cuticular arteries over the surface of the body. In the healthy state it is slightly acid and saline. According to Lavoisier and Seguin, the greatest amount of perspiration exceeds six pounds in the twenty-four hours, and the smallest two pounds; it is at its maximum immediately after taking food, and decreases during digestion. Whatever quantity of food is taken, or whatever are the variations of the atmosphere, the same person, after having increased in weight by all the food he has taken, returns in twenty-four hours nearly to the same weight he was the day before, provided he is not growing and has not indulged in any excess.

The substances perspired are water, carbonic acid, saline substances, lactic acid, and some organic matter. In certain cases of disease, the perspiration is not only greatly modified as to quantity, but often as to quality.

PERTURBA'TION. In Astronomy, the deviation of a celestial body from the elliptic orbit which it would describe if acted upon by no other attractive force than that of the sun, or central body about which it revolves. If the planets exercised no attraction on each other, the orbit described by each of them would be accurately an ellipse, having the sun in one of its foci; and the law of the motion such that the area described by a straight line joining the centre of the sun and the planet would describe equal areas in equal times. But in consequence of the universal gravitation of matter, every body in the system is more or less affected by the attractive influence of all the others, and is consequently forced to deviate from the path it would describe in virtue of the central force acting alone. The forces which cause these deviations are called the *perturbing* forces; and the determination of their effect on each orbit is the great problem of physical astronomy.

The simplest case of the problem is a system in which there are only three bodies, — a central body and two revolving bodies, disturbing the motions of each other. Such, for example, would be the case of the sun, the earth, and the moon, if all the other planets were conceived to be annihilated, or at so great a distance that their disturbing force was rendered insensible. For the sake of perspicuity, let one of the revolving bodies be called the *disturbed* and the other the *disturbing* body. Now it is by no means difficult to obtain a general idea of the effects that must be produced by the disturbing force. It is easy to see, for example, that in certain positions of its orbit the motion of the disturbed body must be accelerated, and in others retarded; that in one case it may be drawn above, and in another depressed below the plane of the orbit it would describe about the central body. But a far more difficult problem remains — namely, that of determining the ultimate effect of the reciprocal action of the revolving bodies after an infinite number of revolutions. When the masses and distances of the bodies are supposed to be given, this is a problem of pure mathematics; but such is its difficulty that even when restricted to three bodies, its general solution transcends the power of analysis; and it is only in a particular case (that, however, which is presented by nature), namely, when the mass of the disturbing body is very small in comparison of the central one, that mathematicians have succeeded in integrating the equations of motion, and determining the final results.

It is easy to conceive that if the problem presents great difficulties when only three bodies are taken into consideration, these difficulties must be infinitely increased when it is attempted to investigate the reciprocal actions of all the individuals composing the solar system. To determine the circumstances of the motions of about thirty bodies projected in space and abandoned to their mutual attractions, is a problem indeed which far transcends the power of any known calculus. Nevertheless there are circumstances in the peculiar constitution of the solar system which enable us not only to foresee the general effect, but to determine the form and dimensions and position of an orbit, and the place of the body it, at any given time, past or future, with all the precision which astronomical observations admit of. These circumstances are the following: — In the first place, by reason of the immensely preponderating attraction of the sun, the force by which any planet is attracted by another is extremely feeble in comparison of that by which it is retained in the orbit it would describe if there was no other body than itself and the sun. Hence the deviations from that orbit are small, and the disturbing action of each planet admits of being computed independently of the others. In the second place, all the large planets are confined to a zone of a few degrees in breadth, and therefore can exert only a comparatively feeble influence in drawing one another from the planes of their orbits. In the third place, the system is broken up into subordinate and partial systems, which are almost independent of one another. Thus, for example, the Sun, Jupiter, and Saturn form a system, in which the two planets exert a very sensible action on each other, but are very little affected by the influence of any other body; and the same is the case, though in a less degree, with Venus and the Earth. By reason of these circumstances, mathematicians have been enabled to accomplish what would otherwise have been impossible, and to express the disturbing forces of the several bodies of the system by algebraic equations, from which the positions of all the planets and the principal satellites are computed for several years to come, and reduced into tables for the purposes of navigation.

The inequalities produced in the motions of the planets by their reciprocal actions are divided into two kinds. The first depend on the *configurations* of the planets, that is, the relative positions they have with regard to each other; and, as the inequalities depending on this cause increase, diminish, and disappear after certain intervals of time, they are called *periodic inequalities*. Those of the second kind are independent of the relative positions of the planets: they are also periodic, but their periods are incomparably longer than those of the first kind; hence they are called *secular inequalities*, as if their periods were not to be reckoned by years, but by centuries. It is by the discovery of the periodic nature and ultimate compensation of all the inequalities of both kinds, occasioned by the perturbing forces, that the permanent stability of the system is demonstrated.

In order to assure the stability of the planetary orbits, three elements must remain constant, or be subject only to small periodic fluctuations. These are, 1. The major axis of the orbit, or the planet's mean distance from the sun; 2. The inclination of its orbit to a fixed plane; and 3. The eccentricity of the orbit. Now, with respect to the major axes, it has been demonstrated by Lagrange that they are exempted altogether from secular inequalities, and are subject only to periodical changes depending on the configurations of the planets. They are therefore restored to their former values when the planets resume the same relative positions; and their mean values, and consequently the mean motions which depend upon them, remain unalterably the same. With regard to the inclinations and eccentricities, they are affected both by periodic and secular inequalities; but their secular changes are confined within very small limits, and ultimately work out a compensation. Besides, the inclinations and eccentricities of the different orbits are connected with each other in such a manner, that whatever any one orbit gains in either of these respects is lost among the others. These relations are defined by the two following theorems discovered by Lagrange, than which analysis has furnished no more remarkable or beautiful results: —

1. If the mass of every planet be multiplied by the square root of the major axis of its orbit, and the product by the square of the tangent of its inclination to a fixed plane, the sum of all these products will be constantly the same under the influence of their mutual attraction.

2. If the mass of each planet be multiplied by the square root of the axis of its orbit, and the product by the square of the eccentricity, the sum of all such products throughout the system is invariable.

From the periodic nature of the changes produced in the three elements mentioned above, it follows that the whole effect of the perturbing forces is to cause the system to oscillate about a mean state, and that the inequalities of the planetary motions are all compensated in the long run; and that consequently the system contains within itself no element of destruction, but is calculated to endure for ever, unless an external force be introduced. These results of theory are, in a speculative point of view, by far the most interesting in the whole range of astronomical discovery. They are not deduced, however, from the solution of the general problem of the motion of bodies mutually attracting each other, but are founded on certain conditions which belong to the individual system; viz. 1. That the eccentricities of the orbits are inconsiderable; 2. That the inclinations to the plane of the ecliptic are small; and, 3. That all the planets, primary and secondary, move in the same direction. Now these conditions are not necessary consequences of gravitation. For any thing that has been proved to the contrary, a system might exist under the Newtonian law of gravitation in which not one of them would be satisfied. Of their final causes, however, we are, and may ever remain, entirely ignorant; but the fact of their existence (for the chances are almost as infinity to one

that they are not accidental) proves clearly enough that the primitive impulse which determined the directions of the different motions must have been communicated to all the planets and satellites by the same mechanical cause.

The history of the problem of the perturbations dates from the discovery of universal gravitation. Newton himself pointed out the general effects which the mutual attractions of the planets must have in disturbing the motions of each other, and applied his theory to the investigation of the precession of the equinoxes, and the inequalities of the moon. The problem of three bodies was solved by Clairaut, D'Alembert, and Euler, about the middle of the last century. Euler first pointed out the periodic nature of the variations of the orbits of Jupiter and Saturn occasioned by their mutual perturbations. Laplace remarked that on taking account of some of the first terms of the analytical development of the expressions of the perturbed orbits, those on which the secular inequalities depend are capable of increase only within certain limits; and Lagrange demonstrated generally that no secular inequality, or term proportional to the time, can possibly enter into the expression of the greater axis of the orbit, or the mean motion which depends on it. It may be said that the discoveries of these two great mathematicians completed the theory of gravitation, inasmuch as every inequality in the system not previously accounted for was by them referred to its proximate cause, and its analytical expression assigned. The labours of all succeeding mathematicians in the department of physical astronomy have been confined to the extension and simplification of their theories.

For a popular account of this subject, the reader may consult *Laplace's Système du Monde, Sir J. Herschel's Treatise on Astronomy*, and *Airy's Gravitation*. The mathematical theory is contained in the *Mécanique Céleste*, and other works on physical astronomy. (See, also, *Playfair's Outlines of Nat. Phil.; Woodhouse's Astronomy*, vol. ii.; Pontécoulant, *Théorie Analytique du Système du Monde;* Gautier, *Essai Historique sur le Problème des Trois Corps*.)

PERTU'SSIS. The whooping cough.

PERU'VIAN BALSAM. The produce of the *Myroxylon Peruvianum;* a tree which grows in the warmest parts of South America. It is obtained by boiling the twigs in water. It is a thick brown liquid, of a fragrant odour, and a pungent and bitterish flavour.

PERUVIAN BARK. *See* CINCHONA.

PERVIGI'LIUM. (Lat. from vigil, *watchful;* a watch lasting through the night.) The nocturnal festivals to some deities were so styled by the Romans. The *Pervigilium Veneris*, a beautiful relic of Latin poetry, is attributed by some critics to Catullus.

PESTILENCE. (Lat. pestis.) Any contagious or infectious disease which is endemic or epidemic, and mortal. The term is also used in a moral sense. *See* PLAGUE.

PE'TALISM. (Gr. πεταλον, *a leaf.*) In Antiquity, a form of condemnation practised at Syracuse, by which persons who from their wealth or influence were considered dangerous to the state were banished for five years, with leave to enjoy their estates and to return after that period. It was in fact only another form of the Athenian ostracism (*see* OSTRACISM); with this difference, that in the latter the condemnation was written on shells and lasted for ten years, whereas in petalism leaves were made use of, and the condemnation lasted only five years.

PE'TALITE. A Swedish mineral of a grey or reddish colour and a foliated texture. It is a silicate of alumina and lithia, and contains between five and six per cent. of the latter alkali.

PETALO'CERANS, *Petalocera*. (Gr. πεταλον, *a leaf;* κερας, *a horn.*) A tribe of Coleopterous insects, including those which have antennæ terminated by a foliated mass.

PETALOI'DEUS. (Gr. πεταλον, and ειδος, *like.*) A term applied by botanists to any organ the texture and colour of which resemble a petal.

PETALS. (Gr. πεταλον.) In Botany, the divisions of the corolla of a plant.

PETA'RD. (Fr.) In Artillery, an engine formerly much used for breaking down gates, barricades, &c. The petard had some resemblance to a high-crowned hat. It was formed of gun metal, was about seven inches deep, and five inches in diameter at the mouth, and held from nine to twenty pounds of gunpowder. When about to be used it was screwed to a thick plank, and suspended before the gate to be burst open. Petards were first used by the French Hugonots at the siege of Cahors in 1579. Their use is now discontinued; and it has been discovered that gunpowder in loose bags is equally efficacious.

PE'TASUS. (Gr.) A broad-brimmed hat used on journeys by the classical ancients; hence a petasus with wings attached to it is the emblem of the celestial traveller Mercury.

PETAURIST, *Petaurus*. (Gr. πεταω, *I expand*, and ουρα, *a tail.*) The name of a genus of Marsupial animals, which have the power of taking extensive leaps through the air, like the flying squirrel, by means of outstretched tegumentary folds between the fore and hind extremities, aided by an expanded tail.

PETE'CHIÆ. (Ital. petichia.) Small red spots produced by the effusion of drops of blood in the skin, immediately under the cuticle. They resemble flea-bites, and usually indicate an altered and impure state of the blood.

PE'TER-PENCE. The popular name of an impost, otherwise termed "the fee of Rome," or, in the Anglo-Saxon, "Romescot:" originally a voluntary offering by the faithful to the see of Rome; afterwards a due levied in various amounts from every house or family in a country. Peter-pence were paid in France, Poland, and other realms. In England this tax is recognized by the Norman laws of William the Conqueror. Edward III. discontinued the payment when the popes resided at Avignon; but it was afterwards revived, and finally ceased in the reign of Henry VIII.

PE'TIOLE. That portion of a leaf that connects the lamina with the stem of a plant; the footstalk.

PETI'TION (Lat. peto, *I ask*), signifies generally a supplication preferred by one person to another, who is supposed to be capable of granting the request. The right of the British subject to petition either house of parliament, or the king, is founded on the Bill of Rights. But this act is not considered as having repealed 13 C. 2. stat. 1. c. 5., by which it is criminal to solicit or procure the putting the hands of more than twenty persons to a petition for alterations in church or state, unless by consent of three or more justices, or a majority of the grand jury at assizes or sessions, &c.; and repairing to the king or parliament to deliver such petition with above the number of ten persons is also rendered criminal.

PETITION. In Law, an application in writing, addressed to the Lord Chancellor, the Master of the Rolls, or to the equity side of the Court of Exchequer, in which certain facts are set forth as the ground on which the petitioner rests his prayer for the order and direction of these respective courts. Petitions are of two kinds, — *cause petitions*, or *exparte petitions*. The former are those in regard to matters of which the court is already in possession, by virtue of there being a suit concerning their substance (the petitioner in this case being either generally a party to such suit, or in some way or other possessing an interest therein); the latter (*exparte petitions*) are so called when there is no suit existing about the matter of the petition. Both these kinds of petitions are susceptible of numerous subdivisions.

PETI'TIO PRINCI'PII. (Lat. *a demand of the principle.*) In Logic, a popular designation for a species of vicious reasoning, which consists in tacitly assuming the proposition to be proved as a premise of the syllogism by which it is to be proved; vulgo, *begging the question*.

PETONG. The Chinese white copper; it is an alloy of copper and nickel. *See* PAKFONG.

PETRELS. In Ornithology. *See* PROCELLARIÆ.

PETRIFA'CTIONS. (Lat. petra, *a stone*, and facio, *I make.*) A general term by which naturalists designate the conversion of vegetable or animal materials into a stony substance. The word is equivalent with such expressions as "organized fossils, organic remains," &c.; which however, are all liable to exception on the ground of not distinctly explaining what they are meant to define; and though the term *petrifaction* is itself open to censure on the same score, it does not seem that any other word more acceptable to the naturalist has hitherto been found to supersede it. The branch of science which treats more peculiarly of substances in a petrified state is usually denominated *Oryctology*, which see.

PETROBRU'SIANS. The followers of Peter de Bruys, a heretic or reformer of the 12th century, who declaimed with great success against the vices of the clergy, and gathered around him considerable numbers of adherents in the south of France. The exact opinions which he advanced are only to be collected from the assertions of his adversaries, who, at a time when the lower classes throughout Europe were listening eagerly to violent and perhaps fanatical oppugners of the dominant church, did not fail to exaggerate and discolour their doctrines to suit their own purposes. Besides the vague charge of Manicheism which was made against most of these sectarians, the imputations cast upon them chiefly refer to their contempt for the ordinances of the church; in which it is very probable that, along with the real abuses of the day, the crucifixes, images, and relics, the ignorant multitude may have included the sacraments and other purer ceremonies in one indiscriminate abhorrence. A treatise was composed against them by St. Bernard. (See *Faber's Albigenses and Waldenses; Waddington's History of the Church*, ch. xviii.)

PETRO'LEUM. A brown liquid bitumen, found in several parts of Europe, in Persia, and in the West Indies. It is often termed *Barbadoes tar*.

PE'TROLINE. A substance obtained by distilling the petroleum of Rangoon; analogous to *paraffine*.

PE'TROSI'LEX. A variety of flint or hornstone. The term is sometimes applied to compact felspar.

PETU'NTZE. (Chinese.) A decomposing variety of felspar, used in China in the manufacture of porcelain.

PETWORTH MARBLE, called also *Sussex Marble:* It is a variously coloured limestone, occurring in the weald-clay, and composed of the remains of fresh-water shells. *See* GEOLOGY.

PEUTINGE'RIAN MAP or TABLE. (Germ. Peutinger Tafel; so called from Conrad Peutinger, a native of Augsburg, who was the first to make it generally known.) The name given to a map of the roads of the ancient Roman world, written on parchment, and supposed to have been constructed about the time of Alexander Severus, A. D. 226. The original, which is 21 feet in length, and only about 1 foot in width, is deposited in the imperial library at Vienna; but copies of it are to be found in the *Ptolemy* of Bertius; in Horne, *Orbis Delineato;* in Bergier, *Historique des Grands Chemins de Empire Romain;* and part of it in *Murray's Encyclopædia of Geography*. Combined with the celebrated *Antonine Itinerary*, which it serves admirably to illustrate, though it differs from the latter in several essential particulars, the Peutingerian Table may be justly regarded as one of the most valuable bequests of ancient geography to modern times. In this table the high road which traversed the Roman empire in the general direction of east and west is made the first meridian, and to this every part is subjected. The objects along this line are minutely and faithfully exhibited; but of those lying to the north and south of it only some general notion can be conveyed. From the novel and peculiar construction of the table, every object is of course enormously extended in length and reduced in breadth. (See *Mannert's Introduction* to his new edition of the *Peutingerian Table*, Leipsic, 1824.)

PEW'TER. An alloy of tin with lead and antimony frequently bears this name; but the best pewter was formerly made of 12 parts of tin with 1 of antimony, and a very small addition of copper. A fine pewter is made, according to Aiken, by fusing together 100 parts of tin, 8 of antimony, 1 of bismuth, and 4 of copper. The use of these additions to tin is to harden it and preserve its colour; and a good pewter, when clean and polished, has a silvery lustre, and does not readily tarnish. Common pewter, of which measures and pewter pots are made, is an alloy of lead and tin.

PHAËTON. (Gr. φαέθων, *shining*.) In Mythology, the son of Apollo and Clymenes; one of the Oceanides, according to most writers. The fable of his adventures is well known. Taunted with his doubtful origin, he asked his father to lend him the chariot of the sun for a day, as a proof of his filial rights. Unable to guide the fiery steeds, he was dashed to the ground by Jupiter with a thunderbolt, to prevent his consuming the heavens and earth. The best known narrative is that in *Ovid's Metamorphoses*.

PHAGEDÆ'NIC. (Gr. φαγειν, *to eat*.) A term applied to ulcers which rapidly corrode and destroy the parts which they attack.

PHALA'NGER, *Phalangista*. (Gr. φαλαγξ, *a phalanx*.) The name of a genus of Marsupial animals, including those in which the second and third toes of each hind foot are united together as far as the last phalanx in a common cutaneous sheath, and which have a hinder thumb, but no lateral cutaneous parachute.

PHALA'NGES. In Anatomy, the small bones of the fingers and toes.

PHALA'NGIUM, or SHEPHERD-SPIDER. The name of a genus of Arachnidans, including those in which all the legs are very long and slender; the tarsi sometimes consisting of more than fifty joints.

PHA'LANX. (Gr. φάλαγξ.) The close order of battle, in which the heavy-armed troops of a Grecian army were usually drawn up. There were several different arrangements of the phalanx peculiar to different states; but the most celebrated was that invented by Philip of Macedon. The men stood close together, sometimes with their shields locked, in ranks of several men in depth, displaying in front a row of long-extended spears. The phalanx, whose charge was irresistible in a smooth plain by a lighter body, was found to be overmatched by the combined strength and activity of the Roman legion, which was able to take advantage of any inequality of ground, and charge in flank and rear; and when once an accident offered an opening in the unwieldy mass of the enemy, their confusion was inevitable, and rally hopeless. The phalanx is described in most works on Grecian antiquities; but see especially the *Mem. de l'Ac. des Inscr*. vol. xxiv. xxv., and the Essay in vol. xli. by M. de Maignal.

PHA'LERA. In Roman Military Antiquities, various kinds of ornaments were so called, chiefly but not exclusively appropriated to the equipment of horse soldiers; it was also applied to the frontlets of the horses themselves. It is evidently, however, as the ornament of the man, and not the horse, that Virgil uses the word in the lines —

Euryalus phaleras Ramnetis et aurea bullis
Cingula . . . . humeris nequicquam fortibus aptat.

(See the 3d and 22d Memoires of M. le Beau on the Roman Legion, in *Mem. de l'Acad. des Inscr*. vols. xxviii. and xxxix.)

PHA'LEROPE, *Phaleropus*. (Gr. φαλερος, *scolloped*, and πους, *a foot*.) The name of a wading bird, with the toes provided with scolloped membranes.

PHA'NERONEURANS, *Phaneroneura*. (Gr. φανερος, and νευρον, *a nerve*.) A name applied by Rudolphi to all those animals in which the nerves are distinctly eliminated.

PHANTA'SMAGO'RIA. (Gr. φαντασμα, *appearance, spectre*, and αγορευομαι, *I collect*.) An optical apparatus, by means of which the images of objects can be magnified or diminished at pleasure, and motion given to them whereby a strong illusion is produced. The apparatus is in fact nothing more than a magic lantern, in which the images are received on a transparent screen, and the sliders on which the figures are drawn rendered perfectly opake, excepting in the figures themselves; so that all light is excluded, excepting that which is transmitted through the image. The lantern, mounted on wheels, is made to recede from or approach to the screen, by which the enlargement or diminution of the image is effected; and in order to preserve distinctness in the picture, the tube in the side of the lantern which carries the lens is, by a particular mechanism, drawn out or pushed in, so as to increase or diminish the distance between the lens and the slider, according as the lantern approaches to or recedes from the screen. The phantasmagoria affords a very popular exhibition in lecture rooms. (See *Hutton's Dictionary; Young's Natural Philosophy; Halle's Natürl. Magie*.)

PHA'RISEES. A sect among the Jews, whose name is derived from *Pharas*, a Hebrew word signifying *separated* or *set apart;* because theyseparated themselves from the rest of the nation, and pretended to the distinction of peculiar holiness. The time of their origin is not accurately determined; but they are referred to by Josephus as a considerable sect, B. C. 110. In the time of our Saviour they constituted the most influential party among the Jews. Though their rivals the Sadducees numbered amongst themselves some individuals of the highest rank, and those who affected to be conversant with the manners and philosophy of the Greeks and Romans, the Pharisees embraced a greater proportion of the upper classes, and were supported by the admiration of the people, and the national feeling in favour of the opinions and habits of their ancestors. Besides being strict interpreters of the written law, their sect superinduced upon it what they called the traditions of the elders, and asserted that Moses delivered an oral law as a supplement to that of the scriptures. They are frequently reproached by our Saviour with explaining the latter by the former, so as in effect frequently to destroy the validity of the written law. They also attached a mistaken importance to many outward ceremonies of human invention, which they observed with a studied ostentation which gained for them the esteem and veneration of the multitude. They maintained, in opposition to the Sadducees, the popular doctrine of the resurrection; which, however, they appear to have corrupted with some vague notions touching the transmigration of souls.

PHARMACO'LOGY. (Gr. φαρμακον, *a medicine*, and λογος.) The history of the properties and uses of drugs.

PHA'RMACOPŒIA. (Gr. φαρμακον, and ποιειν, *to make*.) A book containing directions for the preparation of medicines.

PHA'RMACY. (Gr. φαρμακον.) The branch of knowledge which relates to the medical and chemical history of the different articles of the *Materia Medica;* to the mode of prescribing them, their effects, and composition.

PHARMA'KOLITE. In Mineralogy, a term applied to the native arseniate of lime.

PHA'ROS. Properly the name of an island at the mouth of the harbour of Alexandria, on which a lighthouse was erected; whence it came to be applied as a common name for all lighthouses. *See* LIGHTHOUSE.

PHARYNGO'TOMY. (Gr. φαρυγξ, and τεμνω, *I cut*.) The operation of making an external opening into the windpipe, necessary in certain cases of suffocation.

PHA'RYNX. (Gr. φερειν, *to convey;* because the food is conveyed by it into the œsophagus and stomach.) The back part of the mouth: it is somewhat funnel-shaped, attached to the fauces behind the larynx, and terminating in the œsophagus.

PHASCOLA'RCTOS. (Gr. φασκωλος, *a pouch*, and αρκτος, *a bear*.) The name of a genus of Marsupial animals, of which the koala is the type: its dentition is like that of the kangaroo rats; but it has no tail, and has short hind legs.

PHA'SCOLOME, *Phascolomys*. (Gr. φασκωλος, and μυς, *a mouse*.) The name of a Marsupial quadruped, commonly called the wombat, which has the teeth of a

Rodent animal, with the exception of an additional true molar on each side of both jaws.

PHASE (Gr. φασις, *appearance*), in Astronomy, denotes the different appearances of the moon or inferior planets, according as a greater or smaller portion of the hemisphere illuminated by the sun is visible to the observer. The phases of the moon sometimes denote in particular the new moons, the full moons, and the quarters, these being the principal phases.

PHASE, in Natural Philosophy, denotes the particular state, at any given instant, of a phenomenon which undergoes a periodic change, or increases to a given point, and then diminishes in a regular gradation. Thus we speak of the *phase of a tide*, the *phase of an eclipse*, &c.

PHASIA'NIDÆ. (Gr. φασιανος, *a pheasant*.) The name of the family of Gallinaceous birds of which the genus *Phasianus* is the type. The pheasant is a native of warmer and drier climates than England, as the Linnæan specific name (*Phasianus colchicus*) implies. Cuvier states that it was brought from the banks of the Phasis by the Argonauts, and subsequently became diffused over all temperate Europe. It is consequently a matter of difficulty to preserve the species in this country; and were it not for the assistance which the common fowl affords in hatching the eggs of the pheasant, the breed would probably soon become extinct; for although the female produces a great many eggs in the artificial preserves of the wealthy sportsman, yet she soon forsakes the task of incubation, when disturbed, as is too often the case, by the male.

When roused the pheasant will not unfrequently perch upon the first tree; and seems more intent upon the dogs than the approach of the sportsman: they betray themselves likewise by the habit which they have of crowing or making a chuckling noise at the time when they perch. Foxes destroy many pheasants; and as these are commonly females engaged in incubation, the tendency to diminution of the race from this cause is increased. But the chief loss of the pheasant-breeder is caused by the mortality of the young birds, about the time of changing their nestling feathers, produced by the development of great numbers of a peculiar species of Entozoon (*Syngamus trachealis*) in the windpipe. This accumulation occasions a difficulty of breathing; and the convulsive attempt to gasp the air, or expel the worms, has occasioned the name of "the gapes" to be given to this disease.

The best remedy is a preventive treatment, by due attention on the part of the keepers to the young pheasants in keeping them clean, and administering plenty and variety of food. When the disease is far advanced, obliging the birds to breathe air strongly impregnated with fumes of tobacco, carefully watching its effect, is the best remedy.

The male pheasant is distinguished, like most *Gallinacea*, by its superiority in size and brilliancy of plumage from the female; and the dependency of this difference on the generative function is proved by the remarkable instances of assumption on the part of the female of more or less of the male livery, consequent upon the abrogation of that function in her either by age or by injury or disease of the female organs. The food of the pheasant varies according to the season: in winter it consists chiefly of grain and seeds; in spring and summer of insects and nutritive bulbous roots, as that of the "crow-foot" (*Ranunculus bulbosus*).

The pure breed of *Phasianus colchicus* is distinguished by the absence of the white ring round the neck, and the reddish copper tint of the croup. Another species, from China, with a white ring round the neck, and a greener cast of colour, especially upon the croup, has also been imported and turned wild. It seems to have produced a prolific race of hybrids with the common pheasant.

China produces several other species, which are remarkable for their superb and brilliant plumage; as the golden pheasant (*Ph. pictus*), Amherst's pheasant (*Ph. Amherstii*); both of which have a gorgeous ruff round the neck, and the latter is remarkable for its exceedingly long tail. A like appendage characterizes the magnificent Reeves's pheasant (*Ph. Reevesii*). The silver pheasant (*Ph. nycthemerus*) from China, and the *Phasianus lineatus* from the mountains of Thibet, approach nearer in their carriage to the common fowl.

PHE'NECIN. (Gr. φοινιξ, *purple*.) The purple powder which is precipitated when sulphuric solution of indigo is diluted with water. It appears to be a hydrate of indigo.

PHENGI'TES MARBLE. *See* MARBLE.

PHENO'MENON; plural, *Phenomena*. (Gr. φαινω, *I shine*.) In Natural Philosophy, this term is usually applied to those appearances of nature of which the cause is not immediately obvious: such as the phenomena of light, of the magnet, of electricity, &c., produced by physical experiments; or unusual natural appearances, as meteors, comets, earthquakes, &c., which occur without the intervention of human agency.

PHIGA'LIAN MARBLES (so called from having been discovered near the site of Phigalia, a town of Arcadia), the name given to a series of sculptures in alto relievo, now deposited in the British Museum, where they form part of the collection known by the name of the *Elgin Marbles*. They originally formed the fringe round the interior of the cella of the temple dedicated to Apollo the Deliverer; a title conferred on him by the Phigalians in gratitude for his having delivered them from a pestilence. They represent the combat of the Centaurs and the Lapithæ, and that of the Greeks and Amazons. The similarity, both in design and execution, which they bear to the decorations on the Parthenon leaves no doubt that they are the workmanship of the same master minds which designed, constructed, and adorned that splendid monument of the golden age of art. *See* PARTHENON, ELGIN MARBLES.

PHILADE'LPHES. (Gr. φιλεω, *I love*, αδελφος, *brother*.) A secret society said to have existed in France during the government of Napoleon, and to have produced the conspiracy of Colonel Malet in 1812. An account of it is given, but we do not know how far it is to be understood as narrating matters of fact, in the *Histoire des Sociétés Sécretes de l'Armée*, published in 1814.

PHILANTHRO'PINISM. A name given in Germany to the system of education on natural principles, as it is termed, which was promoted by Basedow and his friends in the last century, and mainly founded on the notions of Locke and Rousseau. An institution for the purposes of education, founded under the protection of the Duke of Dessau in 1774, was the first so called "Philanthropin." It was dissolved in 1793; and of the similar institutions afterwards founded, only one, it is said, has continued to maintain itself. But the influence of the labours of the Philanthropinists has undoubtedly entered largely into the modern system of education. (*Conv. Lex.*)

PHILANTHROPY. (Gr. φιλεω, *I love*, and ανθρωπος, *a man*.) A general term for a benevolent feeling towards the whole human race. It is opposed to misanthropy.

PHILIBEG, or FILIBEG. *See* KILT.

PHILI'PPIC. The title of several orations of Demosthenes against Philip king of Macedon, the spirit and animosity of which has caused the name to be transferred to similar compositions. Thus Cicero gave this name to the orations which drove Mark Antony from Rome, and impelled the senate to prosecute the war against him after the murder of Julius Cæsar.

PHILOCTE'TES. In Mythology, the son of Pæan; according to some authors, one of the Argonauts. The friend and companion of Hercules, and one of the most celebrated heroes of the siege of Troy, though but little referred to in the *Iliad*. His adventures, too long to be here recounted, form the subject of one of the tragedies of Sophocles.

PHILO'LOGY. (Gr. φιλεω, *I love*, and λογος, *speech, discourse*.) This word appears to have been used by the classical ancients to designate the whole circle of belles-lettres, and even of the sciences: cultivated as they then were very imperfectly, and more in a theoretical than an inductive shape; considered, not with respect to their respective subject matters, but to the language in which they were conveyed. A philologist was one who studied or taught the elegance of diction, as applicable to every branch of human learning; nor can the meaning of the designation be very accurately distinguished from that of the γραμματικος, or grammarian: while sometimes the term philology was usurped in a wider sense, so as to comprehend learning in general. After the revival of letters, the word was introduced into modern European languages, but in a much more restricted signification. It then comprehended grammatical criticism and etymology, and some branches of archæology; and as these studies were almost confined to the ancient languages, and other relics of classical antiquity, which alone were then studied in a scientific manner, the only philologists were the learned investigators of the Greek and Latin idioms and literature. Commentaries on ancient authors, etymological works, and glossaries of their language, grammars, &c. were then the class of writings usually denominated philological; and although the field of philology, considered in this sense, is now more extensive, as the modern European and non-European languages have also become the subjects of accurate investigation, it is with the same general meaning that the word is chiefly used, at least among English writers, at the present day. It is defined by Johnson "criticism, grammatical learning." In this popular sense philology may be said to embrace, 1. Etymology, or the science of the origin of words; 2. Grammar, or the science of the construction of language in general and of individual languages; 3. Literary criticism, or the investigation of merits and demerits in style and diction.

Of late years, however, a new and very extensive province has been added to the dominion of philology; namely, the science of language in a more general sense, considered philosophically with respect to the light it throws on the nature of the human intellect and progress of human knowledge; and historically, with refer-

ence to the connection between different tongues, and the connection thus indicated between different nations and races. Some attempts have recently been made to confine the use of the word philology to this particular branch of learning. It comprehends, 1. *Phonology*, or the knowledge of the sounds of the human voice; which appears to include orthography, or the system to be adopted when we endeavour to render, by our own alphabet, the sounds of a foreign language; 2. *Etymology*; 3. *Ideology*, or the science of the modification of language by grammatical forms, according to the various points of view from which men contemplate the ideas which words are meant to express.

Classical Philology.—By German writers the use of the word philology is still not uncommonly restricted to this branch of study. The earliest commentators, lexicographers, and grammarians, whose works we possess, flourished in Greece and Rome at various periods between the Christian era and the fall of the Roman empire. During the middle ages the knowledge of the classical languages, or of the works written in them, ceased to be cultivated as a science. Philology was revived about the end of the 14th and beginning of the 15th century, and chiefly by the labours of various learned Greeks expelled from their own country by the encroachments of the Romans. In the 15th century, Italy was peculiarly animated with a zeal for classical literature, which, in fact, essentially injured, during the whole of that period, the cultivation of the native language of the country. In the following age, the cultivation of this study passed chiefly into the hands of the French, Dutch, and Germans; nor was it long retained in any perfection among the students of the first of these nations. In the hands of the industrious writers of Holland and Germany classical philology assumed a new form. Less elegant, and pursued in a less poetical mind than it had been among the Italians, it became a vast and laborious science, exacting the severest industry, and no common ingenuity. During the 16th and 17th century, philologists may be said to have been chiefly occupied in collecting the materials of knowledge: the task of criticism, and of separating the true from the false in classical idiom and diction, began with the 17th; and the earliest name in this department of study is perhaps still the most illustrious; that, namely, of Richard Bentley. Since his time, we have had many distinguished classical scholars in our own country, especially in the present day, which has produced Parr, Porson, and Elmsley; but Germany still remains the true nursery of classical research; and the school of Wolf, Heyne, and Hermann, in that country, has laid down canons of inquiry, as to the genuineness and authority of some of the earliest works in the ancient language, which have imparted a new character to classical criticism in general. *See* LANGUAGE, CLASSICS.

PHILOLOGY, SACRED. The art of criticising the languages and dialects of the Hebrew and Hebræo-Greek writers in order to elucidate the meaning of the sacred Scriptures. The Hebrew language, consisting principally of the old Phœnician, with admixtures of the Aramæan from Mesopotamia, introduced by Abraham and his horde, received also a few modifications, owing to the long servitude of the Israelites in Egypt. How old the book of Job may be, is still a *vexata questio* among critics, some of whom suppose that it was originally written in *Arabic* and afterwards translated, while others trace it to a remote period of *Hebrew* literature; but whether it be older or not than the works of Moses, the Pentateuch must ever be considered the basis of the Hebrew as a fixed written language. The institution of the schools of the prophets under the Judges no doubt tended to give that polish and poetic character seen in the writings of David and Solomon; but the Hebrew language remained essentially the same down to the conquest of Palestine, first by Shalmaneser (who introduced an Aramæan population in lieu of the expelled ten tribes); and secondly by Nebuchadnezzar, who (B. C. 588) took the holy city, and captured the two remaining tribes, transporting them also, according to a still prevalent eastern custom, into his own territories. The Jews, however, during their captivity at Babylon, not only acquired new habits, but received many additions to their language, both of words and idioms; and henceforward they spoke a dialect usually known as the *Hebræo-Aramaic*, bearing nearly the same analogy to the Hebrew that the modern Italian bears to the Latin. In the later historical writers traces may be discovered of this corruption. The prophecies of Haggai, Zechariah, and Malachi, also, though very pure, present a few instances of Chaldeism; but the new dialect is most of all perceptible in the Targums and other uninspired commentaries by which alone the Scriptures could be made intelligible to the common people. Schultens, Rosenmüller, the elder Michaelis, Bishops Louth and Horsley, Gesenius, Ewald, and Prof. Lee have successfully laboured in elucidating the history of the Hebrew language; and the best editions of the Hebrew Scriptures are by Kennicott and De Rossi. After the cessation of Hebrew prophecy on the death of Malachi, about 400 years B.C., the Aramæan dialect prevailed more or less, owing to the adherence of the Jews to their national language, down to the capture of Jerusalem by Titus. The conquests of Alexander, however, had an undoubted influence over the learned castes, who gradually became acquainted with the Greek language; and accordingly (B. C. 280), Ptolemy Philadelphus invited *five* Jewish scribes to Alexandria for the purpose of translating into Greek the Pentateuch, that part of the Jewish history relating to the Egyptians. Some years afterwards the other books of the Old Testament were translated by different hands; but the name *Septuagint* (*see* SEPTUAGINT) is a misnomer; and the story connected with it (resting wholly on the very questionable authority of Plutarch and Diodorus Siculus) is quite unworthy of credit. The work, however, is written in good Macedonian Greek (*κοινὴ διάλεκτος*), with a few Hebrew admixtures; and hence the Septuagint should be studied in connection with the New Testament, which presents similar features. In the time of Christ the Aramaic (as the Gospels furnish abundant proof) was the vulgar language of Palestine; and even Galilee had a separate though cognate dialect. (Luke, xxii. 59.; Acts, ii. 7.) After the descent of the Holy Spirit, the followers of Christ became gifted with that power of expression necessary to carry the tidings of the Gospel into distant countries; and the Greek language, so far as the regions west of Palestine were concerned, was the great medium of communication. Hence the Evangelists and Apostles wrote in this language. But though their ideas were inspired, their words were of their own creation; and hence arose those peculiarities of diction, Hebrew expressions, &c., the understanding of which is absolutely necessary to an intimate acquaintance with the inspired writers of Christianity. This, indeed, constitutes the science of sacred philology; and in this work the labours of Wetstein, Mill, Griesbach, and Scholz have been employed in producing a pure Greek text from the examination of the best MSS.; while the most celebrated critics of the New Testament, Bengel, the younger Michaelis, Küinoel, De Wette, Bp. Marsh, Stuart, Ernesti, Winer, and Robinson have spent their best days in elucidating the meaning of the Evangelists and Apostles—the great pillars of the church, of which Christ is the head corner-stone.

PHILO'SOPHER'S STONE. *See* ALCHEMY.

PHILO'SOPHY (Gr. φιλεω, *I love*, and σοφία, *wisdom*), in common acceptation, is a general term, signifying the sum total of systematic human knowledge. It is commonly divided into three grand departments; metaphysics, physics, and ethics. If we include in the first logic, this may be regarded as a complete distribution of science, properly so called. The first has for its object those truths which go beyond mere experience; as the nature of being, of God, of the soul, &c., as they are in themselves, or as they are apprehended by us. (*See* METAPHYSICS.) The second relates to objects as they are in nature, as subject to the relation of cause and effect. The third contemplates human actions as they *ought* to be, not merely as they are; and takes account of the ideas of duty, freedom, responsibility, and the like—of all, in short, which constitutes the distinction between *an action* and *an event*.

This word was first used by the Pythagoreans, and adopted from them by Socrates, who considered himself a lover or seeker of wisdom only; in distinction from a *sophist*, or one who conceives himself to be in the possession or exercise of wisdom.

Many valuable histories of philosophy have appeared of late years, especially in Germany. The most celebrated are those of Brucker, Tennemann, and Ritter. A sketch of the history of philosophy written by the late Mr. Dugald Stewart, originally prefixed to the *Encyclopædia Britannica*, is now printed in a separate volume.

PHI'LTER. (Gr. φιλεω, *I love*.) A drug or preparation supposed by the ancients to have the power of exciting love. Nothing certain is known respecting the composition of these celebrated potions; but there can be no doubt that recourse was frequently had to them by the ancients, and that their operation was so violent that many persons lost their lives and their reason by their means. The Thessalian philters were in the highest celebrity. (See *Juv.* vi. 610.)

PHI'LYRA. In Mythology, one of the Oceanides, and mother of the centaur Chiron by Saturn, who visited her in the shape of a horse. Alarmed at the monstrosity of her offspring, she implored Saturn to change her nature; when the god granted her request, and changed her into a linden tree, which is still called in Greek by her name. Her son received the gift of immortality.

PHLEBO'TOMY. (Gr. φλεψ, *a vein*, and τεμνω, *I cut.*) The operation of opening a vein for the purpose of taking away blood.

PHLEGE'THON. (Gr. φλεγέθων, *burning*.) The mass of fire which, according to the poets of Rome and Greece, washed the shores of the infernal regions. It is

also the name of one of the rivers of the infernal regions. *See* Cocytus.

PHLOGI'STON. (Gr. φλογιζω, *I burn.*) An imaginary principle, by which Stahl and the chemists of his school accounted for the phenomena of combustion; the matter of fire fixed in combustible bodies.

PHLYCTÆ'NA. (Gr. φλυκταινα.) A small vesicle which contains a serous fluid.

PHLYZA'CIUM. (Gr. φλυζειν, *to be hot.*) A pustule upon the skin.

PHOCA'CEANS, *Phocacea*, or Seal Tribe. The name of the family of carnivorous and amphibious Mammals of which the seal (*Phoca*) is the type. *See* Seals.

PHOCÆ'NA. (Gr. φωκαινα, *a porpoise.*) A subgenus of dolphins, distinguished by the absence of the beak-like prolongation of the jaws.

PHOCE'NIN. A peculiar fatty matter contained in the oil of the porpoise (*Delphinum*). When saponified it yields a volatile odorous acid, called *phocenic acid.*

PHŒ'BUS. (Gr. φοιβος, *brilliant.*) A name of Apollo, often used in the same sense as Sol.

PHŒNICO'PTERUS. (Gr. φοινιξ, *red*, and πτερον, *a wing.*) The generic name of the flamingo: also a term applied to other animals which have red wings, as the *Bombycilla phœnicoptera.*

PHŒ'NIX. In Mythology, a bird of great celebrity among the ancients; and, from the peculiar circumstances connected with its origin, longevity, and death, regarded as the emblem of immortality. She was described as of the size of an eagle, her head finely crested, her body covered with a beautiful plumage, and her eyes sparkling like stars. She was said to live 500 or 600 years in the wilderness, when she built for herself a funeral pile of wood and aromatic gums, which she lighted with the fanning of her wings, and thus *apparently* consumed herself, but not *really;* this being merely the process by which she endowed herself with new vitality: she then

> Mounts from her funeral pyre on wings of flame;
> And soars and shines, another and the same!

Four periods of history are mentioned by ancient writers as having been graced by the appearance of the phœnix. The first was in the reign of Sesostris; the second in that of Amasis; the third in that of Ptolemy III., king of Egypt; and the fourth in that of Tiberius. There is, however, a great discrepancy of opinion on this point, as well as on every other relating to the phœnix. The history and imaginary attributes of the phœnix have formed a theme to poets in every age; and in most languages its name has passed into a proverb. By the fathers of the church it was frequently brought forward as an illustration of the doctrine of the resurrection (see Spanheim, *De Usu et Præstantia Numismatum*, diss. v. c. 13., and the authorities cited in that learned work); and it appears on the coins of several Roman emperors, sometimes as a symbol of their own apotheosis, sometimes as an emblem of the renovation of the world and the revival of the golden age under their beneficent rule. The chief ancient authorities with regard to the phœnix are Herodotus, b. ii. c. 73.; Ovid, *Met.* xv. 391.; Pliny, *Hist. Nat.* x. 2.; and Tacitus, *Annal.* vi. 18. Besides these, the reader may consult, in the third volume of Wernsdorf, *Poetæ Minores* (to which the editor has prefixed a learned introduction), the poem *De Phœnice*, which is usually attributed to Lactantius, and in which every circumstance on record with regard to the phœnix has been chronicled with the most laborious precision. The reader will also find in Metral's work, *Le Phœnix, ou l'Oiseau du Soleil* (Paris, 1824), a resumé of all that has been written, both in ancient and modern times, respecting the history and peculiarities of the phœnix.

Phœnix. One of the modern constellations in the southern hemisphere.

PHOLA'DEANS, *Pholadeæ*. (Gr. φωλεος, *a lurking place.*) The family of Lamellibranchiate Bivalves of which the genus *Pholas* is the type: they are remarkable for the *hiding places* which they excavate for themselves in rocks and clay.

PHONE'TIC WRITING. (Gr. φωνη, *sound.*) That writing in which the signs used represent sounds; in opposition to *ideographic*, in which they represent objects, or symbolically denote abstract ideas, as in the figurative part of the Egyptian hieroglyphics. The signs representing sounds are usually arbitrary, or at least have become so in process of time; as in the ancient Roman alphabet, of which the letters are for the most part derived from the Hebrew or Phœnician, in which languages they may have originally partaken of a symbolical character. But, in a species of phonetic writing which is intermixed with the figurative hieroglyphics in Egyptian inscriptions, every letter is denoted by a figure representing some object, the name of which begins with that letter. *See* Hieroglyphics.

PHO'NICS. (Gr. φωνη.) The doctrine of sound: the same as *acoustics*. (*See* Sound.) As sound, like light, is subject to certain laws of reflection and refraction, the science, like that of light, may be treated under three heads; namely, direct, reflected, and refracted sound. In allusion to the corresponding branches of optics, these have been denominated *phonics, cataphonics*, and *diaphonics.*

PHO'NOLITE. (Gr. φωνη, and λιθος, *a stone.*) A species of compact basalt; sonorous when struck.

PHO'RCUS. In Mythology, a marine deity, son of Pontus and Terra; father of the Gorgons, the dragon that guarded the apples of the Hesperides, and other fabulous monsters.

PHORONO'MIA, or PHORONO'MICS. (Gr. φερω, *I bear or carry.*) A term sometimes used to denote the science of motion. In this sense, it was employed by Hermann, a mathematician who flourished in the beginning of the 18th century, in a work entitled *Phoronomia, seu de Viribus et Motibus Corporum Solidorum et Liquidorum* (Amstel. 1716), and of great merit for the time in which it appeared. The term mechanics being now employed generally to signify the doctrine of moving bodies, *phoronomia*, or *phoronomics*, seldom occurs in works of modern science.

PHO'SGENE GAS. (Gr. φως, *light*, and γιγνομαι, *I produce.*) A compound of chlorine and carbonic oxide, made by exposing equal measures of those gases to the sunshine, or to bright daylight. They will not unite in the dark.

PHO'SPHATES. Salts containing *phosphoric acid.*

PHOSPHITES. Salts containing *phosphorous acid.*

PHOSPHORE'SCENCE. The emission of light by substances at common temperatures, or below a red heat.

PHOSPHORESCENT ANIMALS. Those species are so called which have the faculty of emitting a luminous fluid. They are much more numerous than the electric animals; belonging to most of the Invertebrate classes, and frequently rendering vast tracts of the ocean luminous by their prodigious numbers. The glow-worm (*Lampyris*), the phosphorescent sea-pen (*Pennatula phosphorea*), and the brilliant pyrosome (*Pyrosoma Atlanticum*), are amongst the most remarkable of these animals.

PHO'SPHORITE. Native phosphate of lime.

PHO'SPHORUS. (Gr. φως, *light*, and φερω, *I carry.*) So called from its property of shining in the dark. It was discovered in 1668 by Brandt, an alchemist of Hamburgh, and was originally obtained by distilling urine; but it is now always extracted from *bone earth*, by a process contrived by Scheele. The bones are calcined, so as to destroy the animal matter, and, being powdered, are mixed with water, to which half their weight of sulphuric acid is added. The bone earth, consisting chiefly of phosphate of lime, is thus decomposed, sulphate of lime is formed, and phosphoric acid is evolved; or, rather, superphosphate of lime, which, being much more soluble than the sulphate, remains in the liquid, and may be obtained by its evaporation: it is mixed with about half its weight of charcoal, and put into a well-luted earthen retort, the beak of which dips into water. At a bright red heat, the phosphorus distils over into the water. It is purified by carefully melting it under water, and straining it through a piece of chamois leather.

Pure phosphorus is almost colourless, and semitransparent; it may be cut with a knife, and its surface has a waxy lustre. It fuses at 108°, boils at 550°, and is converted into vapour, having, according to Dumas, a density $= 4 \cdot 35$. It is sparingly soluble in fixed and volatile oils, and in ether and alcohol; but insoluble in water. It shines in the dark, and emits a luminous vapour, undergoing a slow combustion, and exhaling a peculiar smell like garlic. When rubbed, or heated to a temperature of about 110°, it takes fire and burns with great rapidity, with a white flame, emitting abundance of acid fumes; in oxygen gas its combustion is so intensely brilliant that the eye can scarcely bear the light.

The product of the perfect combustion of phosphorus is *phosphoric acid*, a fusible substance, very soluble in water, and intensely sour. It appears to consist of 1 equivalent of phosphorus $= 16$, and $2\frac{1}{2}$ of oxygen $= 20$; its equivalent being 36.

There are two other acids of phosphorus; namely, the *phosphorous acid*, consisting of 16 phosphorus + 12 oxygen; and the *hypophosphorous acid*, which appears to be a compound of 2 equivalents of phosphorus $(16 \times 2) = 32$, and 1 of oxygen $= 8$. When phosphorus is boiled in a solution of caustic potash a gas is evolved, which is remarkably distinguished by its spontaneous inflammability; each bubble, as it rises through the water, taking fire upon the surface, and producing a beautiful ring of smoke: this gas is commonly called *phosphuretted hydrogen.* Phosphorus may be made to combine with the greater number of the metals, forming compounds called *phosphurets.*

PHOTOGE'NIC DRAWING. (Gr. φως, and γιγνομαι, *I generate.*) When the article Daguerrotype was written, under which we have adverted to the extraordinary results obtained by Daguerre, the mode by which they were produced had not been made public; since that time, however, all the details of the manipulation have been fully

disclosed, and they are extremely interesting and curious, though the explanation or theory of the process is still somewhat obscure. The whole subject has lately acquired much additional importance from its extended applications; namely, from architectural objects, sculpture, and interiors of rooms, to portraits, and more lately to groups, and even whole-lengths; and it is undergoing almost daily extension and improvement.

The outline of the process is as follows: — A piece of copper is plated in the usual way with silver by passing the metals together through a rolling mill, and is then cut into pieces of a proper size. The silver surface is carefully polished, and cleansed by wiping it over with a piece of cotton dipped in dilute nitric acid, washing, and drying. When thus duly prepared, — and much depends upon the manner in which these preliminary operations are performed and the materials used, — the plate is subjected to the diffused vapour of iodine, which forms a slightly brown or yellow film upon the silver; it is then ready to be subjected to the action of the image to be represented, which is thrown upon it, care being taken to exclude all other light, by an instrument upon the principle of the camera obscura. In the course of a few seconds or minutes, the requisite time depending upon the intensity of the light, the plate is removed; and though nothing is as yet visible upon it, it has received the image, which is brought out and rendered evident by subjecting it, inclined at an angle of about 45°, to the vapour of mercury. This operation is performed in a box with a glass side, at the bottom of which is a basin of mercury heated to about 170°, so that the operator may see the progress of the appearance of the image, and remove the plate when it is perfect; but light must be as far as possible excluded, and more especially daylight. The plate is then washed by cautious immersion in a solution of hyposulphite of soda, and lastly with boiling distilled water, and allowed to dry: it is now perfect, may be exposed to light without injury; but must be carefully protected from all friction by covering it with a glass. The action of the various shades of light upon the film of iodine, and the subsequent influence of the mercurial vapour, upon which the visibility of the picture depends, have not been satisfactorily explained, and require further experimental elucidation. The perfection of the drawing, and the extraordinary manner in which the minutest details are represented, we have noticed in our former article; they must, however, be seen to be accurately judged of and duly appreciated.

The term "Photogenic Drawing" has usually been applied to a process very different from the preceding; namely, to representations of various objects upon paper imbued with some of the salts of silver. If a piece of paper be dipped into a weak solution of nitrate of silver, carefully dried, and preserved out of the contact of light, it remains white; but if exposed to light it gradually becomes discoloured, acquiring a brownish or grey tint, and ultimately blackens, the depth of colour depending upon the intensity of the light and duration of exposure. If any opaque or translucent object be laid upon a sheet of paper so prepared, so as wholly or partially to intercept the incident light, a representation of the object is obtained upon the paper. Where the light has been wholly intercepted, it remains white; where partially so, various shades are produced; and wherever the light has fallen without interruption, the utmost blackness is obtained. If, for instance, a portrait painted in transparent colours upon a plate of glass be laid upon a piece of the prepared paper, and exposed to the solar light, a copy is obtained in which the lights of the original are shades, and the shades lights in proportion to their intensity; but if such a picture be taken upon a very thin piece of paper, this may be again copied by a repetition of the process, and then the lights and shades will be as in the original. It is, however, obvious that such a photograph will only be durable whilst kept in the dark, and that exposure to light will gradually obliterate the whole; to fix it, the paper must be washed in a solution of hyposulphite of lime or of soda, which removes all remaining and unaltered salt of silver, but leaves the image untouched. In this process the paper, after having been impregnated with nitrate of silver, or with ammonia-nitrate of silver, is generally dipped in a solution of common salt, by which chloride of silver is formed, and this is more susceptible of the influence of light than the mere nitrate.

In this article we have merely given an outline of the theory of the process of photogenic drawing; the use of nitrate of silver for this purpose, and the mode of copying paintings on glass, was originally suggested about forty years ago by Mr. Wedgwood and Sir H. Davy. The interest excited by Daguerre's discoveries induced various experimentalists to resume the inquiry; and many new and important facts connected with it have accordingly been brought to light, especially by Mr. Fox Talbot and Sir J. F. W. Herschel, whose communications are published in the *Philosophical Transactions;* and by Mr. A. Taylor, who has written a small tract upon the subject.

PHOTOGRAPHY. *See* PHOTOGENIC DRAWING.

PHOTO'METER. (Gr. φως, *light*, and μετρον, *measure.*) An instrument for measuring the intensity of light, or of illumination.

The most elegant instrument which goes under this name is the photometer invented by the late Sir John Leslie. It is merely the differential thermometer of the same ingenious philosopher, having one of its balls diaphanous, and the other coated with China ink, or blown of deep black enamel; and the whole covered by a case of thin transparent glass, to defend the balls from the disturbing influence of currents of air. The photometer has two general forms; the one *portable* (fig. 1.), in which the black ball is about an inch higher than the other, and bent forward to the same vertical line, or the axis of the translucent cylindrical case; and the other *stationary* (fig. 2.), having both its balls of the same height, and reclining in opposite ways; the case being composed of a wide cylinder surmounted by the larger segment of a hollow glass sphere. The latter form of the instrument, though less commodious, is better adapted for nice observations; since, besides receiving the light more regularly, its balls, from being on the same level, are not liable to be any how disturbed in their indications by different strata of unequally heated air.

(1.) (2.)

The theory of this photometer depends on the assumed principle that the intensity of light is proportional to the heat excited by its incidence on the black ball. When the instrument is exposed to light, the rays which fall on the clear ball pass through it, without suffering obstruction; but those which strike the dark ball are stopt and absorbed at its surface, where, assuming a latent form, they act as heat, which, by expanding the air within the ball, causes the liquid in the stem to descend. This heat will continue to accumulate till its farther increase comes to be counteracted by an opposite dispersion, caused by the rise of temperature which the ball has acquired. But, in still air, the rate of cooling is, within moderate limits, proportional to the excess of the temperature of a given surface above that of the surrounding medium. Hence the space through which the coloured liquid sinks in the stem will measure the momentary impressions of light, or its actual intensity. (*Leslie on the Relations of Air to Heat and Moisture.*)

The graduation is entirely arbitrary, and may be regulated according to fancy or convenience. Leslie adopted the same scale of divisions as in the differential thermometer, ten degrees of which correspond to one of the centigrade thermometer. When the temperature of both balls is exactly the same, that is, when the instrument is excluded from light, the liquid in the stem next the coloured ball stands at zero. In this country the direct impression of the sun at noon, about the summer solstice, forces the liquid down to 90° or 100°. The greatest force of the solar beams, in the depth of winter, measures only about 25°. At the altitude of 3° above the horizon, the whole effect of the sun's rays does not exceed one degree. The indirect light from the sky at noon in summer is from 30° to 40°; in winter from 10° to 15°. Comparing the illuminating power of the solar rays with that of artificial lights, Leslie found the light emitted by the sun 12,000 times more powerful than that of a wax candle; that is to say, if a portion of the luminous solar matter, rather less than half an inch in diameter, were transmitted to our planet, it would throw forth a light equal to the effect of 12,000 candles.

It has been objected that the instrument now described is only a species of thermometer, and not strictly a photometer; since it measures heat, and not light. To this objection Sir J. Leslie replies by asking, "What does the thermometer itself indicate except *expansion?* As heat is measured by the expansion it occasions, so light is determined by the intensity of the heat which in every supposition invariably accompanies it. What other mode, after all, could be imagined for detecting the presence of light? How can an unknown quantity be expounded but in terms of one already known?" (*Ency. Brit.*, art. "Climate.")

It must be admitted, however, that the same quantity of light emitted by terrestrial bodies of different kinds is not always accompanied with the same degree of heat. Thus, phosphorus burns in oxygen gas with intense splendour, and yet gives out far less heat than the comparatively dull combustion of hydrogen in the same gas; and the photometer is more affected by a fire so dull that not a single letter could be discerned in a well-printed page, than by the degree of daylight by which the same page could be read with pleasure and facility. For a particular description of the photometer, and an account of its numerous applications, see *Leslie's Experimental Inquiry into the Nature and Propagation of Heat*, 1804.

PHOTO'METRY. (Gr. φως, and μετρον, *measure.*) The science which treats of the measurement of light. Attempts to determine the relative intensities of different

lights were made at an early period in the history of experimental science. For the purpose of comparing the light of Sirius with that of the sun, the celebrated Huygens employed a tube having a very small aperture at one end, into which was inserted a minute globular lens, which allowed only the 27664th part of the solar disk to be seen, and this small portion afforded a light which appeared equally bright with Sirius; whence he concluded the distance of Sirius to be 27664 times greater than that of the sun. (*Huygenii Cosmotheoros.*) Celsius appears to have been the first who proposed to measure light directly by means of what he called a *lucimeter*. His method, however, which was an extremely imperfect one, consisted simply in observing the greatest distance from the eye at which small circles painted on paper were distinctly visible in different lights. It was reserved for Bouguer to establish photometry on true principles. Having been induced by Mairan's remarks on the relative proportion of the sun's light at the summer and winter solstice to investigate the subject, he undertook a series of experiments, of which the results were first published in his *Essai d'Optique*, 1729; and afterwards in his *Traité d'Optique sur la Gradation de la Lumière*, which appeared in 1760, two years after his death. In the same year appeared the *Photometria* of Lambert; in which the subject was treated more generally, and with great mathematical elegance. The principle adopted by Bouguer and Lambert is extremely simple. Though the eye cannot judge of the proportional force of different lights, it can distinguish in many cases with great precision when two similar surfaces presented together are equally illuminated, or when the shadows of an opaque object thrown upon them by different lights are equally dark. But, as the particles of light proceed in straight lines, they must spread uniformly, and hence their density will diminish in the duplicate ratio of their distances. From the respective situations, therefore, of the centres of divergency when the contrasted surfaces become equally bright, we may easily compute their relative degrees of illumination. The objection to this method is that the apparatus admits of no certain standard of comparison. Even the light of the sun itself, at the same altitude, and in the same climate, is subject to considerable variation; much more so any artificial light, the force of which must always be influenced by a number of undefinable circumstances. In this respect, therefore, the photometer described in the preceding article has a great and decided advantage.

A simple and elegant application of the principle of Bouguer was made by the late Dr. Ritchie. His apparatus consists of a rectangular box, about an inch and a half or two inches square, open at both ends and blackened within, to absorb extraneous light. Within, inclined at angles of 45° to its axis, are placed two rectangular plates of plane looking-glass, cut from one and the same strip, to ensure equality of their reflecting powers, and fastened so as to meet at the top, in the middle of a narrow slit about an inch long and an eighth of an inch broad, which is covered with a slip of fine tissue or oiled paper. In comparing, by means of this instrument, the illuminating powers of two different sources of light, they must be placed at such a distance from each other, and from the instrument between them, that the light from every part of each shall fall on the reflector next it, and be reflected to the corresponding portion of the oiled paper. The instrument is then moved nearer the one or the other, till the two portions of the paper corresponding to the respective mirrors are equally illuminated, of which the eye can judge with considerable certainty.

The modification of this method, which consists in contrasting the shadows of an opaque object formed by different lights, is usually ascribed to Count Rumford, by whom it was proposed in the *Phil. Trans.*, vol. lxxxiv., but was long before used by Lambert. It is generally supposed that the equality of two shadows can be appreciated with more certainty than that of two lights; but, when the lights are of different colours, their estimation by either method admits of little precision.

M. Arago has proposed a method of determining the relative intensities of different lights entirely different in principle from any of the preceding, and probably susceptible of much greater accuracy. It is founded on the properties of polarized light. When two lights are to be compared, the rays from each are polarized by causing them to pass through a plate of tourmaline cut parallel to the axis, or by reflecting them from a plate of glass, on which they fall at the polarizing angle. They are then received on a plate of rock crystal, cut perpendicularly to the axis, and observed through a doubly refracting prism. Each light will thus give two images tinged with the complementary colours. The images are then brought into such a position that the red of the one falls over the green of the other. If the two lights are equal in intensity, this superposition will produce a white image; if unequal, the image will be slightly coloured with red or green, according as the one or the other predominates. The apparatus which this method requires is somewhat complicated, and its manipulation must be attended with considerable trouble. (See the Notes to the French translation of *Sir J. Herschel's Treatise on Light*, Paris, 1833.)

PHOTOPHO'BIA. (Gr. φως, *light*, and φοβεω, *I terrify*.) An intolerance or dread of light; it is a symptom of internal ophthalmia.

PHRASE. (Gr. φρασις, *speech or expression.*) In Music, a short melody in which a perfect musical idea is not entirely developed.

PHRASEO'LOGY (Gr. φρασις, and λογος, *science*), properly the science or knowledge of style; but used in common language to signify the peculiarities of diction of a writer, school, &c.

PHRA'TRY. (Gr. φρατρία.) A subdivision of Athenian citizens, analogous to the Spartan *obe* and Roman *curia*, distinguished by particular rites and ceremonies that bound its members together. Each of the four ancient tribes was divided into three phratries, and each phratry into thirty sections or clans, which bore a name exactly answering to the Roman *gens* (γένος); and this division remained subsequently to and independent of the ten tribes of Cleisthenes. The free Athenians registered their own or their adopted children in the phratries to which they themselves belonged, at the festival of the Apaturia; but what the age of registry was is uncertain.

PHRE'NIC. (Gr. φρενες (plural of φρην, *the mind*), *the diaphragm.*) Relating to the diaphragm.

PHRENI'TIS. (Gr. φρην, *the mind.*) Inflammation of the brain or its membranes.

PHRENO'LOGY (Gr. φρην, *the mind*, and λογος, *discourse*), ought, according to its etymology, to signify mental philosophy. The word has, however, been appropriated by craniologists, on account of the light which their observations of the convolutions of the brain, and corresponding elevations on the skull, are supposed to throw on the nature and province of our different faculties. Those who wish to judge how far this pretension is justifiable may consult the works of Dr. Spurzheim and of Mr. Combe on the subject. These gentlemen divide our faculties into three classes: the intellectual or perceptive, the sentiments or emotions, and the animal propensities. To the first of these is assigned the anterior portion of the head; the second occupies the middle and upper; while the posterior region and the cerebellum are allowed to the third and most inglorious division. That this distribution, in its general outline, is borne out by facts, observation is sufficient to convince us; but whether the subdivision of those regions into minute special organs corresponding to distinct faculties is equally well supported, and whether the mental analysis implied in it can be considered sound and accurate, are questions which our limits forbid us to discuss. We subjoin, however, for the reader's convenience in consultation, the following outline of the different faculties, with their uses and abuses, which we have borrowed from the Introduction to Mr. G. Combe's *Notes on the United States of America, during a Phrenological Visit in* 1838-9-40, as probably containing the most recent as well as the most authentic account of the present state of this much canvassed science. The subjoined figure will be of use in illustrating the observations.

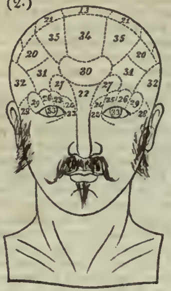
This figure shows the three great phrenological divisions of the brain. The line B runs through the centre of ossification of the parietal bone (the organ of Cautiousness, No. 12.), and terminates in the centre of ossification of the frontal bone situated at the point where it touches the line A A (the organ of Causality, No. 35.) The portion above the line B is named the coronal region, and serves to manifest chiefly the moral sentiments. The line A corresponds to the posterior lateral edge of the superorbitar plate, on which

the anterior lobe of the brain rests. The space before the line A A indicates the size of the anterior lobe, the region devoted to the manifestation of the intellectual faculties. If the space before the lower A be long, the organs of the observing faculties are large; and if the space forward from the point where the line B meets the line A A be long, the reflecting organs are large. The space below B and behind A A manifests the propensities common to man with the lower animals. We may remark that in the above figure the coronal region would be said to be large, indicating powerful moral sentiments; the intellectual region about an average, and that of the so called animal propensities moderate.

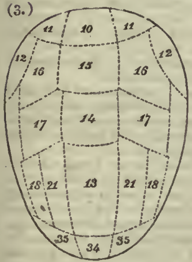
The faculties generally recognized by phrenologists are the following.*

(1.)

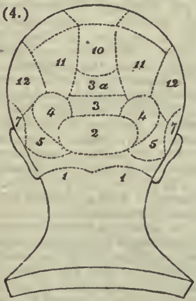
(2.)



(3.)



(4.)



Order I. Feelings.

Genus I. Propensities — *Common to Man with the Lower Animals.*

† The Love of Life.
Appetite for Food. — *Uses:* Nutrition. — *Abuses:* Gluttony and drunkenness.

1. Amativeness — Produces sexual love.

2. Philoprogenitiveness. — *Uses:* Affection for young and tender beings. — *Abuses:* Pampering and spoiling children.

3. Concentrativeness. — *Uses:* It renders permanent emotions and ideas in the mind. — *Abuses:* Morbid dwelling on the internal emotions and ideas, to the neglect of external impressions.

3. *a.* Inhabitiveness. — *Uses:* It produces the desire of permanence in place. — *Abuses:* Aversion to move abroad.

4. Adhesiveness. — *Uses:* Attachment, friendship, and society result from it. — *Abuses:* Clanship for improper objects, attachment to worthless individuals.

5. Combativeness. — *Uses:* Courage to meet danger and overcome difficulties, tendency to oppose and attack whatever requires opposition and to resist unjust encroachments. — *Abuses:* Love of contention, and tendency to provoke and assault. This feeling obviously adapts man to a world in which danger and difficulty abound.

6. Destructiveness. — *Uses:* Desire to destroy noxious objects, and to kill for food. It is very discernible in carnivorous animals. — *Abuses:* Cruelty, murder, desire to torment; tendency to passion, rage, and harshness and severity in speech and writing. This feeling places man in harmony with death and destruction, which are woven into the system of sublunary creation.

7. Secretiveness. — *Uses:* Tendency to restrain within the mind the various emotions and ideas that involuntarily present themselves until the judgment has approved of giving them utterance; it is simply the propensity to conceal, and is an ingredient in prudence. — *Abuses:* Cunning, deceit, duplicity, and lying.

8. Acquisitiveness. — *Uses:* Desire to possess, and tendency to accumulate articles of utility to provide against want. — *Abuses:* Inordinate desire of property, selfishness, avarice, theft.

9. Constructiveness. — *Uses:* Desire to build and construct works of art. — *Abuses:* Construction of engines to injure or destroy, and fabrication of objects to deceive mankind.

Genus II. Sentiments.

I. *Sentiments common to Man with the Lower Animals.*

10. Self-esteem. — *Uses:* Self-respect, self-interest, love of independence, personal dignity. — *Abuses:* Pride, disdain, overweening conceit, excessive selfishness, love of dominion.

11. Love of Approbation. — *Uses:* Desire of the esteem of others, love of praise, desire of fame or glory. — *Abuses:* Vanity, ambition, thirst for praise independently of praiseworthiness.

12. Cautiousness. — *Uses:* It gives origin to the sentiment of fear, the desire to shun danger, and circumspection; and it is an ingredient in prudence. — *Abuses:* Excessive timidity, poltroonery, unfounded apprehensions, despondency, melancholy.

13. Benevolence. — *Uses:* Desire of the happiness of others, universal charity, mildness of disposition, and a lively sympathy with the enjoyment of all animated beings. — *Abuses:* Profusion, injurious indulgence of the appetites and fancies of others, prodigality, facility of temper.

II. *Sentiments proper to Man.*

14. Veneration. — *Uses:* Tendency to venerate or respect whatever is great and good; gives origin to religious adoration. — *Abuses:* Senseless respect for unworthy objects consecrated by time or situation, love of antiquated customs, abject subserviency to persons in authority, superstitious awe.

15. Firmness. — *Uses:* Determination, perseverance, steadiness of purpose. — *Abuses:* Stubbornness, infatuation, tenacity in evil.

16. Conscientiousness. — *Uses:* It gives origin to the sentiment of justice, or respect for the rights of others, openness to conviction, the love of truth. — *Abuses:* Scrupulous adherence to noxious principles when ignorantly embraced, excessive refinement in the views of duty and obligation, excess in remorse or self-condemnation.

17. Hope. — *Uses:* Tendency to expect future good; it cherishes faith. — *Abuses:* Credulity with respect to the attainment of what is desired, absurd expectations of felicity not founded on reason.

18. Wonder. — *Uses:* The desire of novelty; admiration of the new, the unexpected, the grand, the wonderful, and extraordinary. — *Abuses:* Love of the marvellous and occult; senseless astonishment; belief in prodigies, magic, ghosts, and other supernatural absurdities.

19. Ideality. — *Uses:* Love of the beautiful and splendid, desire of excellence, poetic feeling. — *Abuses:* Extravagance and absurd enthusiasm, preference of the showy and glaring to the solid and useful, a tendency to dwell in the regions of fancy and to neglect the duties of life.

19. *a.* The organ of Sublimity; but not sufficiently ascertained.

20. Wit — Gives the feeling of the ludicrous, and disposes to mirth.

21. Imitation — Copies the manners, gestures, and actions of others, and appearances in nature generally.

Order II. Intellectual Faculties.

Genus I. External Senses.

Feeling or Touch. Taste. Smell. Hearing. Sight.	*Uses:* To bring man into communication with external objects, and to enable him to enjoy them. — *Abuses:* Excessive indulgence in the pleasures arising from the senses, to the extent of impairing bodily health and debilitating or deteriorating the mind.

Genus II. Knowing Faculties, which perceive the Existence and Qualities of External Objects.

22. Individuality — Takes cognizance of existence and simple facts.

23. Form — Renders man observant of form.

24. Size — Gives the idea of space, and enables him to appreciate dimension and distance.

25. Weight — Communicates the perception of momentum, weight, and resistance, and aids equilibrium.

26. Colouring — Gives perception of colours and their harmonies.

Genus III. Knowing Faculties, which perceive the Relations of External Objects.

27. Locality — Gives the idea of relative position.

28. Number — Gives the talent for calculation.

29. Order — Communicates the love of physical arrangement.

30. Eventuality — Takes cognizance of occurrences or events.

* The organs are double, each faculty having two lying in corresponding situations of the hemispheres of the brain; except in those organs, such as *individuality, eventuality, benevolence,* &c., represented in the fig. by 22, 30, 13, &c., which occupy the central part of the skull.

† These organs are not fully ascertained, but some facts indicate that they lie in the base of the brain. The first is not marked on the bust, but the second is indicated by 6 *a.* on Fig. 1.

31. TIME — Gives rise to the perception of duration.
32. TUNE — The sense of Melody and Harmony arises from it.
33. LANGUAGE — Gives facility in acquiring a knowledge of arbitrary signs to express thoughts, readiness in the use of them, and the power of inventing and recollecting them.

Genus IV. REFLECTING FACULTIES, WHICH COMPARE, JUDGE, AND DISCRIMINATE.

34. COMPARISON — Gives the power of discovering analogies, resemblances, and differences.
35. CAUSALITY — Traces the dependences of phenomena, and the relation of cause and effect.

The most accredited works in favour of phrenology are Mr. Combe's writings, and the *Phrenological Journal*, which is ably conducted. The most hostile inquiry into the pretensions of phrenology to be regarded as a science appeared in 1826, in the *Edinburgh Review*. In that article, which was well known to have emanated from the pen of Mr. (now Lord) Jeffrey, the views of the phrenologists are treated with ridicule, and their weak side subjected to one of the most vigorous attacks ever made in literary criticism.

PHRYGA'NIDÆ. *Case-worm flies.* The family of Trichopterous insects of which the genus *Phrygania* is the type. *See* TRICHOPTERANS.

PHRYGIAN MARBLE. *See* MARBLE.

PHRY'GIANS. An early sect of heretics; so called from Phrygia, the country where they abounded. They regarded Montanus, the founder of the Montanists (which see), as their prophet; and their distinguishing characteristic was the spirit of prophecy to which they laid claim.

PHTHIRI'ASIS. (Gr. φθειρ, *a louse.*) A disease in which the body is overrun with lice.

PHTHISIS. (Gr. φθινω, *I consume.*) Consumption, which see.

PHYCOMA'TER. (Gr. φυκος, *sea-weed*, and μητηρ, *mother.*) The gelatine in which the sporules of Algaceous plants first vegetate.

PHYLA'CTERY. (Gr. φυλακτήριον, *a protection or preservation.*) An amulet or preservative against infection. The phylacteries of the Jews were derived from the injunction contained in Exodus, xiii. 9.; and consisted of slips of parchment inscribed with verses of the law, enclosed in cases, and worn during prayer on the arm and between the eyes.

PHY'LÆ. (Gr. φυλη, *a tribe.*) The tribes into which the whole of Attica was divided in antiquity. Originally there were but four phylæ, which were frequently remodelled, but remained the same in number till soon after the expulsion of the Pisistratidæ, when Cleisthenes caused their number to be increased to ten. What the precise nature of the change effected on this occasion was is not known, but it is probable that the new tribes embraced a large number of citizens that had been excluded from the former. The phylæ were afterwards increased to twelve, by the addition of two in honour of Antigonus and his son Demetrius. The Athenian senate was composed of fifty delegates from each of these tribes.

PHY'LARCH. (Gr. φυλαρχος, *ruler of a phyle.*) An Athenian officer appointed for each phyle or tribe, to superintend the registering of its members and other common duties. The title answers to that of the Roman tribune, but its functions never reached the same importance.

PHYLLO'DIA. (Gr. φυλλον, *a leaf.*) A term applied to the petioles of certain leafless plants which become so much developed as to assume the appearance of leaves, all the functions of which they perform.

PHYLLONY'CTERANS. (Gr. φυλλον, and νυκτερις, *a bat.*) The name of a primary division of the order *Cheiroptera*, including the "foliated bats," or those species which have the ears and nose complicated by grotesque and variously-figured membranous foliations, serving the purpose of antennæ, and augmenting the sense of touch in these night-flying and short-sighted species. The tribe is also characterized by having a single finger, the innermost, armed with a hook-shaped claw, and the molar teeth beset with sharp-pointed tubercles adapted for crushing insects.

PHYLLO'PHAGANS, *Phyllophaga.* (Gr. φυλλον, and φαγω, *I eat.*) The name of a tribe of Marsupials, including the Phalangers, Petaurists, and Koala; also of a tribe of beetles, including those which live by suction of the tender parts of vegetables, as the leaves and succulent sprouts.

PHY'LLOPODS, *Phyllopoda.* (Gr. φυλλον, and πους, *a foot.*) The name of a tribe of Crustaceans, comprehending those in which the feet are of a flattened leaf-like form.

PHY'LLOSTOMES, *Phyllostomata.* (Gr. φυλλον, and στομα, *a mouth.*) A family of bats, including those in which the nose supports a simple leaf-shaped appendage.

PHYSA. (Gr. φυσα, *a bubble.*) A genus of fresh-water snails; so called from the thinness and inflated appearance of the shell. Several species of bubble-shell are found in England; as *Physa fontinalis*, in the Thames; *Physa alba*, in North Wales; *Physa hypnorum*, common in ponds and slow streams.

PHY'SALIS, or PHYSA'LIA. (Gr. φυσα.) The name of a hydrostatic Acalephan, commonly called the Portuguese man-of-war, remarkable for its size, the brilliancy of its hues, and the severe burning pain produced by its contact.

PHY'SALITE. In Mineralogy, a species of topaz.

PHYSCO'NIA. (Gr. φυσκων, *a big-bellied fellow.*) This term is applied to various enlargements of the abdomen unconnected with dropsy or with accumulations of air, such as morbid states of the liver or of the spleen.

PHY'SICS. (Gr. φυσις, *nature.*) The science of nature. In modern language, however, the term has a less general signification than its derivation implies. Nature signifying the assemblage of all the bodies of the universe, the *science* of *nature* comprehends every species of knowledge which regards the external world. But bodies may be studied under three different points of view; they may be examined with relation to their different properties, with relation to their constituent parts, and with relation to their appearances and exterior qualities. These three distinct views give rise to the three great divisions of natural science; namely, *Physics*, *Chemistry*, and *Natural History*. Physics has for its object the properties of bodies, chemistry studies their elementary principles, and natural history observes their physiognomy or external appearance.

PHYSIO'GNOMY. (Gr. φύσις, *nature*, and γνώμων, *a rule or measure.*) The art of interpreting the indications of the inward disposition supposed to be afforded by the outward appearance, especially the features of the face. (See *Lavater's Physiognomy.*)

PHYSIO'LOGY. (Gr. φυσις, and λογος, *a discourse.*) The science of things generated or alive; but usually regarded as the doctrine of vital phenomena. This science is divided, according to the two great classes of generated beings, into *animal* and *vegetable physiology*. Some philosophers have proposed to change the term for "biology;" but the restricted application of *bios* to the life of an individual in other English compound words, as "biography," would be an objection to this change, even if the word physiology were less appropriate than it is, or if its use in the sense above defined had not been sanctioned by philosophers of other nations.

The chief object of the physiologist is to ascertain the precise mode in which each part or organ of a living being reacts when stimulated. When the precise conditions and mode of the reaction of the circulating fluid upon the solids, and reciprocally, are understood, a true and intelligible definition of life may, perhaps, be given.

In animal physiology, the simplest condition under which life can be contemplated is that which it presents in the torpid hybernater.

During this state a dark nutrient fluid, the venous blood (*see* BLOOD), is propelled, by the contractions of a hollow muscle (*see* HEART), along the arteries to every part of the body, whence it is again returned to the heart by the veins. With respect to this chief manifestation of life in the torpid animal it may be asked, What is the cause or condition of the reaction of the fibres of the hollow muscle upon the stimulating fluid? How does each tissue of the body select from the currents flowing through the terminal capillaries the appropriate particles for its growth or reparation, and, in return, add to the blood, either directly or through the medium of lymphatic vessels, its effete particles? These are questions which physiology has yet to resolve: the electric conditions of the parts concerned have not been ascertained. The blood is maintained in a fit state for the preservation of the tissues of the torpid animal by slowly parting with some noxious or useless principles, through the excretion of the kidneys, and of the different mucous and serous surfaces. The reaction of the circulating fluids upon the solids supersedes the ordinary chemical reaction, by which they would be decomposed and destroyed, and thus the torpid animal is kept alive; but it is the life of the plant or of the ovum. The functions of circulation, nutrition, execretion, are manifested when life is thus reduced, as in the plant, to its simplest condition; and these must, therefore, be its most essential actions. In the torpid animal, the phenomena of irritability and contractility of muscular fibre are superadded, as in the action of the heart; and this is dependent on the connection of the muscular fibre with a nerve. The power of the external decomposing forces is increased by elevation of temperature; and the stimulus of heat produces in the torpid animal, in a manner not understood, a reaction of the mucous surface of the lungs: this reaction influences, through the nerves, the muscles of respiration, and atmospheric air is inspired and brought into contact with the thin membrane over which the pulmonary capillaries are richly spread. The result of this contact is the immediate elimination of the carbon

from the blood, which changes its dark for a florid red colour; or converts it from venous to arterial blood.

The blood so changed stimulates in a different and more potent manner the parts over which it is distributed; the heart contracts more vigorously and frequently; the brain and nervous system now receiving more blood, and that of a different kind, begin to react on the application of stimuli to which they were before insensible.

First, self-consciousness; then sensation of external impressions; lastly, the propagation of a stimulus to the muscular system generally, which produces the reaction of vibratile contraction of its fibre, and by which the animal moves its parts upon each other, or its entire body upon external matter, are successively manifested; and to circulation, nutrition, excretion, and respiration, are now added the functions of sensation and voluntary motion. But with this greatly increased activity of the whole organic machinery, there is a proportional increase of vital decomposition; *i. e.* of abstraction by the tissues of assimilating particles from the capillary blood, and of addition to the same of effete particles; and those actions demand not only increased activity in the organs which eliminate the waste and noxious particles from the blood, and expel them from the body, but also a means of supplying new blood. This is effected by digestion, chylification, and lacteal absorption.

It is the consciousness of this want that impels the newly roused hybernating animal to seek for its appropriate food: the first use to which the machine is put is to supply itself with the means for its continued activity; and this completes the circle of the functions by which animal life is maintained, as respects the individual being.

It is a law, that the renovation of the parts of a living body should not be uniform: at first the power is in excess, and the body grows; afterwards it is unequal to the waste, and the body shrinks; it is at no period, perhaps, quite perfect; the machinery of renovation thus in time becomes unequal to its office, and the ordinary chemical decompositions and recompositions take the place of those in which life had before essentially consisted.

A given term of life characterizes each species of animal; but that the species should continue, it is necessary that the death of the individual be compensated for. This is effected by the power which living beings possess of detaching a portion of themselves; which portion contains in itself potentially all the faculties or functions of life; develops their organs progressively, and according to the pattern of the parent from which it was derived; and when arrived at maturity, in like manner generates or separates another portion of itself, with similar powers of development and growth; then decays and dies. Thus the species of living beings are maintained by the function of generation through a long, but apparently not an indefinite period of time; for the history of the changes of the earth's surface teaches us that the duration of the existence of species, as well as of the individual, is limited, and that many species have become extinct. So far, however, as observation has been able to reach, the death of a species seems to have been rather a violent than a natural one. We have, as yet, had no experience of the extinction of a species by a gradual abrogation of the procreative powers in the individuals of successive generations. Of the introduction of new species we know of no natural cause, nor can hardly form a conception of such.

The science of physiology is that of the different functions of which life is the manifestation; that is to say, of circulation, nutrition, excretion, respiration, sensation, muscular contraction, digestion, absorption, generation; with other subordinate faculties, as the maintenance of equable temperature, the production of vocal sounds, the mental phenomena. To explain these functions, we must first know the instruments by which they are performed; secondly, the matters which they attract, those which they reject, and the nature of that which remains; thirdly, by what forces these matters are transported, attracted, retained, and rejected; and finally, the nature of the stimuli appropriate to each part, and the mode in which such part reacts when stimulated. Physiology has thus many departments, and each department has its anatomical, chemical, dynamical, and what may be termed its purely physiological line of research.

PHYSIOLOGY, VEGETABLE. *See* BOTANY.

PHY'SOGRADES, *Physograda.* (Gr. φυσις, *air*, and gradior, *I proceed.* The name of a tribe of Acalephæ, comprehending those which swim by means of air-bladders.

PHYTI'PHAGANS, *Phytiphaga.* (Gr. φυτον, *a plant*, and φαγω, *I eat.*) The name of a tribe of Cetaceous Mammals, synonymous with *Herbivora.* Also applied by Lamarck to a section of his order of Trachelipod Mollusks.

PHYTO'GRAPHY. (Gr. φυτον, *a plant*, and γραφω, *I describe.*) That branch of science which concerns itself with the rules to be observed in describing and naming plants. *See* BOTANY.

PHYTO'LOGY. (Gr. φυτον, and λογος, *a discourse.*) A book containing herbs and plants.

PHYTO'PHAGOUS. (Gr. φυτον, *a plant*, and φαγω, *I eat.*) Plant-eating.

PHYTO'ZOONS, *Phytozoa.* (Gr. φυτον, *a plant*, and ζωον, *an animal.*) This term is applied by various naturalists to different sections of the sub-kingdom *Zoophyta* of Cuvier.

PIA MATER. A thin vascular membrane covering the convolutions of the brain and the spinal marrow.

PIA'NO. In Music. *See* P. &c.

PIA'NO-FORTE. (It.) A musical stringed instrument of the keyed species. Its name, compounded of two Italian words, signifying *soft* and *loud*, was probably given to it to distinguish it from the harpsichord and spinet, in which no lightness of touch could lessen the strength of the sound produced from the quills always striking the strings with equal force; whereas in the piano-forte, the strings are put in vibration by means of small hammers connected by levers with the key or finger board, which hammers quit the string the moment it is struck, a damper falling down upon it the moment the finger quits the key. The invention of the piano-forte is ascribed to a German named Schroeder, who lived at the beginning of last century; but it was first introduced into England in 1766 by Zumpe, by whom it was greatly improved. Within the present century this instrument has received many useful and valuable improvements from the hands both of Englishmen and foreigners; so that it may be now fairly regarded as, next to the organ, the noblest and most elegant instrument in the whole compass of musical practice. Many distinguished musicians have devoted themselves to the composition of pieces for this instrument; and several of the most distinguished composers in modern times, among whom we may mention Hummel, Czerny, Herz, Kalkbrenner, Cramer, Moscheles, Chopin, Thalberg, Liszt, &c., have made the instrument itself almost their exclusive study. There is an excellent article on the piano-forte in the *British and Foreign Review for* 1839.

PI'ARISTS. (Patres Scholarum Piarum.) Members of a religious order founded at Rome by Casalanza, a Spanish nobleman, early in the 17th century. They were bound by a special vow to devote themselves to the purpose of education. They still continue to superintend a great number of schools in Hungary, Poland, Bohemia, &c.

PIA'STRE. A silver coin used in Spain, Italy, Turkey, South America, the East Indies, &c., varying in value in every country. *See* MONEY.

PIA'ZZA. (Ital.) In Architecture, a square open space surrounded by buildings. Improperly used in England to denote a walk under an arcade.

PI'BROCH. Martial music produced by the bagpipe of the Highlanders. It is said to signify also the instrument itself; but the former meaning, if indeed there are *any* instances of the latter to be found in any classical writer, has received the sanction of the two most celebrated poets of their time, Lord Byron and Sir Walter Scott. The connoisseurs, says the latter writer, in pipe-music, affect to discover, in a well-composed pibroch, the imitative sounds of march, conflict, flight, pursuit, and all the "current of a heady fight." (See a note in *Beattie's Essay on Laughter and Ludicrous Composition*, chap. iii., for a description of the nature of the pibroch.) The 17th stanza of the 2d canto of the *Lady of the Lake*, in which the effects of this martial music are so admirably depicted, must be familiar to every reader.

PI'CA. In Printing, a type of a moderate size; so called because it was used in printing the *Pic*, the service book of old Catholic times, which again is supposed to derive its appellation from the *piecolour* of the text and rubric.

PI'CAMAR. The bitter principle of tar; whence it derives its name (*in pice amarum*).

PICA'RDS. The name of a fanatical and immoral sect of Christians who sprang up in Bohemia in the 15th century. They derived their name from Picard, a native of Flanders, who styled himself the New Adam, and attempted to revive the absurdities of the Adamites of the 2d century, in imitating the state of primeval innocence. They were completely annihilated by Zisca, the great general of the Hussites, who, struck with their abominable practices, had marched against them.

PI'CHURIM BEAN. An oblong heavy seed brought from Brazil, and used medicinally in the cure of colic. It has a musky odour, and is supposed to be the produce of a species of *Laurus.*

PICI. (Lat. picus, *a woodpecker.*) The name given by Linnæus to a group of birds corresponding to the *Scansores* and part of the *Passeres* of Cuvier.

PICIDÆ. *Woodpeckers.* The family of birds of which the genus *Picus* is the type.

PI'CKET. In Fortification, a stake used in laying out ground, to mark the bounds and angles. Pickets are of various lengths, according to the purpose they are to serve. One end is sharp and shod with iron, and the other sometimes carries a small flag, for the purpose of rendering it visible at a distance.

PI'CROMEL. (Gr. πικρος, *bitter*, and μελι, *honey.*)

A peculiar substance, of a sweetish bitter taste, which exists in bile.

PICROTO'XIA. (Gr. πικρος, *bitter*, and τοξικον, *a poison.*) A poisonous bitter principle which exists in the *Cocculus indicus*.

PICTS WALL. One of the barriers erected by the Romans across the northern part of our island to restrain the incursions of the Scots.

PICTURE'SQUE. (Equivalent to the Ital. pittoresco, and the Germ. malerisch.) In the strict sense of the word, all objects which afford fit combinations of form and colour for the imitation of the painter. In literary composition, a style which represents objects and events in such a manner as to call up vivid impressions, as it were, of visible reality, is termed picturesque.

A great diversity of opinion prevails as to the precise nature of that quality which peculiarly recommends objects for pictorial representation; but it would be impossible in this place to lay down any general rules on the subject that would be of any use for the guidance ofthe student. Meanwhile, however, it may be necessary to notice the fact, that the term picturesque is used in a totally different sense from that above adverted to, being applied by many writers to such natural objects as have a somewhat rugged appearance, in contradistinction to those objects which have a *sublime* or *beautiful* character. Thus, in water, that of which the surface is broken, and the motion abrupt and irregular; and, among trees, "not the smooth young beech, nor the fresh and tender ash, but the rugged oak or knotty wich elm, is picturesque. Nor is it necessary they should be of great bulk; it is sufficient if they are rough and mossy, with a character of age, and with sudden variations of their forms. Among animals, the ass is generally thought to be more picturesque than the horse; and among horses, it is the wild and rough forester, or the worn-out cart horse, to which that title is applied. In our own species, objects merely picturesque are to be found among the wandering tribes of gipsies and beggars, who, in all the qualities that give them that character, bear a close analogy to the wild forester and the worn-out cart horse; and again to old mills, hovels, and other inanimate objects of that kind." Such objects, it is argued, are neither beautiful nor sublime; and though far less universally pleasing and alluring than those which possess the qualities of beauty or sublimity, are nevertheless endowed with qualities of their own, which are not only highly suited to the painter and his art, but attractive also to the rest of mankind whose minds have been at all cultivated or improved; and to such objects the term picturesque ought to be exclusively applied. It is impossible, we believe, to invalidate this argument, for the circumstances are sufficiently striking and general to admit of a satisfactory solution; though it must be conceded that great caution is necessary before joining a third and distinct character to the two graces which it is universally admitted embellish natural forms — the sublime and beautiful. But on this question our limits preclude us from entering; and we must refer the reader to Price's elaborate work on the *Picturesque* for full information. (See also the *Quart. Rev.* vol. iv.)

PIEDROIT. (Fr.) In Architecture, a pier or square pillar partly hid within a wall. It is without base or capital, therein differing from a pilaster.

PIE'NO. (It.) In Music, a term denoting that the composition where the word is appended is *full*, that is, for all the performers.

PIE POUDRE COURT. In English Law, a court established to decide on the spot disputes arising at fairs or markets. It was styled in Lat. *curia pedis pulverizati*, and derived its name from the itinerant "dusty-footed" dealers (in old Fr. *pied pouldreux*), for whose convenience it was principally instituted.

PIER. In Architecture, the solid between the openings of a building, or that from which an arch springs. An abutment pier, in a bridge, is that next the shore. For the mode of building the piers of a bridge, see BRIDGE.

PIER. In Engineering, identical with mote, and is used to designate the masses of building erected to form harbours, landing places, &c.

PIERCED. In Heraldry, a term used when a charge is represented as perforated, so as to show the field under it.

PIE'RIDES. A name of the Muses, who were so called from Pieria, a district of Thrace. This was also the name of the nine daughters of Pierus, the king of Emathia, whose profound acquaintance with the fine arts tempted them to challenge the Muses to a contest of musical skill; but, being worsted, were changed by the latter into magpies. In memory of their victory over the Pierides, the Muses are considered, by some authors, to have adopted the name.

PI'ETISTS. The name given to certain reformers of the doctrines and practice of the Lutheran church that arose in Germany towards the end of the 17th century, and caused great dissensions in that body. The Pietists may be divided into two classes, of which the one proposed to effect merely an amendment of life and manners, and to promote a more evangelical spirit and conception of gospel truth than was cherished by the reformed churches, which, at the period in question, had degenerated into great coldness and formality. Out of the discussions which this agitation excited there arose, however, a more violent and fanatical sect, who accompanied the assaults they made on the doctrine and discipline of the church by the assertion of various mystical extravagances. Arnold, Dippelius, and Petersen were their most distinguished leaders. The same school of theologians gave birth to the celebrated enthusiast Jacob Behmen. (See *Mosheim*, vol. v. p. 312., trans. 1790.) The term *Pietist* is at present applied, in Germany, much in the same sense of disparagement as the word Methodist is vulgarly used among ourselves, to those persons who make a display of strong religious feelings.

PIEZO'METER. (Gr. πιεζω, *I press*, and μετρον, *measure.*) An instrument for ascertaining the compressibility of liquids.

PI'GMENT. (Lat. pigmentum.) A term applied by anatomists to the mucous secretion which covers the iris of the eye, and gives it its various colours; and to the dark matter which covers the anterior surface of the choroid membrane, and the interior surface of the ciliary processes.

PIGMENT. In Painting, a general term denoting any colour used by artists.

PI'GMY, or PYGMY. (Gr. πυγμαιος, sc. ανηρ, from πυγμη, *a cubit; a diminutive man.*) By ancient authors on natural history this name was applied to a fabulous race of dwarfish and deformed human beings; it is now restricted to a species of ape, the *Simia troglodytes* of Blumenbach, or the Chimpanzee. (See *Tyson's Anatomy of a Pygmie*, with an Essay concerning the Pygmies of the Ancients, fol. 1699.) Ancient fable (as ancient as Homer, *Il.* b. 3.) described a nation of pygmies dwelling somewhere near the shores of the ocean, and maintaining perpetual wars with the cranes; of which Athenæus gives the mythological origin. Ctesias the Greek historian, as quoted by Photius, represented a nation of them as inhabiting India, and attending its king on his military expeditions. Other ancients believed them to inhabit the Indian islands; and Aristotle places them in Ethiopia, Pliny in Transgangetic India. Some modern lovers of the marvellous have constructed these stories from legends of pigmy nations inhabiting the northernmost part of the earth. These numerous fables appear to originate partly, as Strabo long ago observed, in the stunted growth of particular races, under the sufferings of a severe climate or great privations; thus the Esquimaux or Laplanders furnished the ancient Northmen with their legendary "Dwergar," or nations of malicious dwarfs. Some of the low-caste races which inhabit the forests of interior Hindostan are feeble and puny enough to have given origin to the account of Ctesias; while the pygmies of the Malay Archipelago and the interior of Africa were probably apes. (See the *Encyc. Metropolitana.*)

PIG NUT. The bulbous root of the *Bunium bulbocastanum;* so called because pigs are fond of and dig for them.

PIKE. In Ichthyology, the English term for a fish belonging to the order *Malacopterygii*, section *Abdominales*, family *Esocidae*, and genus *Esox*. *See* MALACOPTERYGIANS.

PIKE. In Military affairs, an offensive weapon used in antiquity and modern times down to the invention of the bayonet, by which it has been universally superseded, consisting of a shaft of wood of 12 or 14 feet in length, surmounted with a flat pointed steel, commonly called the spear. It was chiefly used by the infantry.

PILA'STER. (Ital. pilastro.) In Architecture, a square pillar engaged in a wall, usually projecting not more than one fifth or one sixth of its width. Pilasters are subject to the same rules of proportion as columns.

PI'LCHARD. In Ichthyology, the common name for a fish closely resembling the common herring; but smaller, and at the same thicker and rounder. They are found chiefly on the coasts of Devon and Cornwall, particularly the latter, where they are taken in great numbers from July to September. It is a saying of the Cornwall fishermen, that the pilchard is the least fish in size, but greatest in number and for gain, taken from the sea. For some curious details on the pilchard fishery, see the *Com. Dict.*

PILE. In Heraldry, an ordinary which is represented of a wedge-shape, tapering from the chief downwards towards the point; said to represent the piles on which bridges and other erections are founded.

PILE. In Artillery, a heap of shot or shells, piled up by horizontal courses in a pyramidal or wedge-like form. The form of the pile is determined by that of the base, which may be a triangle, a square, or a rectangle. In a triangular pile the base is an equilateral triangle, and there is one shot at the vertex. The number in the successive horizontal courses, reckoned from the top downwards, are represented by the triangular numbers 1, 3, 6, 10 . . . . $\frac{1}{2}n\ (n+1)$, the sum of which is $\frac{1}{6}n\ (n+1)\ (n+2)$; which, therefore, is the number of shot in a pile of n courses. *See* FIGURATE NUMBERS.

If the base is a square, the number in the successive courses is represented by the series of squares 1, 4, 9, 16, &c.; and the number in the pile of n courses is $\frac{1}{6} n (n + 1)(2n + 1)$.

If the base is a rectangle, n the number of shot in the shortest side (or the number of courses), and $n + d$ the number in the longest side, then the number in the pile continued until there is a single row of $d + 1$ shot at the top is $\frac{1}{6} n (n + 1)(2n + 1 + 3d)$.

PILE DRIVER. An engine for driving down piles. It consists of a large ram or block of iron, which slides between two guide posts. Being drawn up to the top, and then let fall from a considerable height, it comes down on the head of the pile with a violent blow. It may be worked by men or horses, or a steam engine.

PILES, in Building, are timbers driven into the ground or bed of a river, for supporting the foundations of an edifice, or the piers of a bridge. They may be round or square, and formed of any wood which does not rot under water: oak, elm, and chiefly fir, are employed. The end of the pile which penetrates the ground is pointed and shod with iron, and the top is bound with a strong iron band or hoop, to prevent the piles from being split by the violent strokes of the ram by which they are driven down.

PILES. A disease originating in the morbid dilatation of the veins of the lower part of the rectum, and upon the verge of the anus, and frequently caused by costiveness and irregularity of alvine evacuation; the contents of the rectum pressing upon the veins, and preventing the return of their blood, so that they become turgid and varicose, often forming bleeding or ulcerated enlargements and tumours. Mild aperients, especially sulphur and castor oil, are necessary in the relief of the early stage of piles: when there is much inflammation, cold and astringent lotions may be used, and the pain is often relieved by fomentation with decoction of poppies. When the tumours are large and flaccid, an ointment of powdered galls, with a little opium and acetate of lead, often affords relief; and, in old relaxed piles, the internal use and local application of copaiba balsam, and even *Ward's paste*, which contains black pepper, do good. In many cases of protrusions of the tumours, they require removal by ligature or by the knife.

PI'LGRIMAGE. A journey undertaken for devotional purposes to some spot hallowed by religious associations. The custom of making these pilgrimages has long been recommended and enjoined by the Roman church, and they are frequently imposed by way of penance; the remission of sins, and various spiritual advantages, being promised as the reward of the faithful and pious pilgrim. There exist traces in the history of the early church of such journeys being occasionally undertaken from the natural motives, we may suppose, of curiosity, or of a deeper interest; in process of time, the custom of celebrating festivals in honour of martyrs at the place of their sepulture drew larger numbers together from a distance, who, doubtless, soon began to look with some complacency upon their own merits in doing honour to the saints at the expense of fatigue or danger to themselves. But the systematic establishment of pilgrimage as a meritorious work seems to be of much later date. That which was undertaken to the tomb of St. Martin of Tours is among the earliest canonically enjoined. Such places of devotion became gradually very numerous; of which, however, Jerusalem was held naturally in the highest estimation. The difficulties which presented themselves to the pilgrims who attempted to accomplish this journey, when Palestine had fallen into the hands of the Saracens, were the proximate cause of the excitement which armed Europe to the rescue of the Holy Land. The cupidity of the persons in whose custody these shrines were, and the immorality which ensued from the desultory habits which the pilgrims acquired, called forth the earliest animadversion of the church, at the council of Chalons in the 9th century; but the evil seems to have continued steadily on the increase, until, at the time of the Reformation, we find what was originally a harmless, and even a pious practice, degenerated into one of the most crying abuses of the ecclesiastical system. The earliest pilgrimage on record is perhaps that of Helena, the wife of Constantine, to the Holy Land. (See *Schrocck's Kirchen Geschichte*, part 5. 8. 19. 23. 25.)

But pilgrimages are not confined to Christian nations. According to a command in the *Koran*, every good Mussulman is enjoined once in his lifetime to repair to Mecca; and there are many other places, especially in Persia, endowed with sufficient sanctity to attract multitudes of pilgrims. The Hindoos have also their pilgrimages, the most celebrated of which is to the city of Juggernaut, where stands the temple erected in honour of the deity of the same name; a full account of which will be found in the *Geo. Dict.*, art. "Juggernaut." Among existing Christian pilgrimages, the most celebrated is that of Marianzell, in Austria.

PILI'DIUM. The orbicular hemispherical shield or apothecium of a lichen, the outside of which changes to powder, as in *Calycium*.

PILLAR. In Architecture. *See* COLUMN.

PI'LLORY. (Fr. pilori; supposed from pilier, *a pillar.*) A wooden engine on which offenders were formerly exposed to public view, and generally to public insult. It was a common punishment in England, and, by the "statute of the pillory," 51 Hen. 3. c. 6., appointed for forestallers, users of deceitful weights, perjury, forgery, &c. By 56 G. 3. c. 138. it was abolished in all cases except perjury; and as it was discretionary in that instance, it had been long wholly disused. It was finally abolished in 1837 by the statute 1 Vict. c. 23. The French punishment of the same description is now termed the "carcan," from the iron collar by which the neck of the criminal is fixed to a post; anciently, "pilori." It is not now specifically appropriated to particular crimes, but in heavy cases accompanies the sentence of imprisonment or forced labour.

PILOSE. (Lat. pilus, *a hair.*) In Zoology, when an animal or part is covered with hair.

PI'LOT. A person qualified and appointed by proper authority to conduct ships in and out of particular harbours, or along certain coasts, at a certain fixed rate, depending on the draught of water. The pilot has the charge of the vessel while in *pilot water*, and the captain or master neglects or opposes the pilot's advice on his own responsibility. (See *M'Culloch's Commercial Dict.*)

PI'MELITE. (Gr. πιμελη, *fatness.*) A green hydrated silico-aluminous mineral, containing oxide of nickel, of a *greasy* feel.

PIME'NTO. The berry of the *Myrtus pimenta*; allspice, or Jamaica pepper. *See* PIPERACEÆ.

PIN. A small bit of wire, usually brass, with a point at one end and a spherical head at the other. No fewer than fourteen distinct operations are necessary in making this little article; for an account of which see *Ure's Dict. of Arts, &c.* There is a good account of this manufacture in *Babbage's Economy of Manufactures*. See also *Wealth of Nations*, p. 3.; where the pin is cited as an admirable instance of the good effects of a division of labour.

PIN. A term of Chinese diplomacy, signifying a petition or address from foreigners to the emperor of China or any of his viceroys or deputies.

PINACOTHE'CA. (Gr. πιναξ, *a picture*, and τιθημι, *I place.*) In Ancient Architecture, the apartment in a house for the reception of paintings.

PI'NCHBECK. An alloy of copper of zinc; a species of brass much resembling what is now termed *Mosaic gold*. It was brought into notice by a person of the above name.

PI'NEAL GLAND. A small heart-shaped protuberance of the brain, hanging by two peduncles from the beds of the optic nerves immediately over the *corpora quadrigemina*. Some fanciful physiologists have asserted that it is the seat of the soul.

PINE. *See* ABIES.

PI'NION. In Mechanics, a small wheel which plays in the teeth of a larger, or sometimes only an arbor or spindle, having notches or leaves, which are caught successively by the teeth of the wheel, and the motion thereby communicated.

PI'NITE. (From the mine *Pini*, at Schneeberg in Saxony.) A soft crystallized mineral, composed of alumine, silex, and oxide of iron.

PINK, DUTCH. In Painting, a colour of a reddish hue.

PI'NNA. (Lat. pinna, *a fin.*) The name of a genus of Ostracean Acephalous Mollusks, commonly called "wing-shells," remarkable for the size of the byssus, by which they adhere to rocks, and which the natives of Sicily manufacture into gloves, socks, and other articles of sale.

PI'NNACE. A small light vessel with sails and oars: it is at present generally understood as one of the boats belonging to a ship of war.

PIN'NACLE. (Lat. pinna.) In Architecture, a small square or polygonal pillar, generally, though not necessarily, applied at the angles of a building, terminating upward pyramidally, and embellished with foliage at the angles of the pyramidal part.

PI'NNATES. A term applied by Linnæus to the feet of those birds which have the toes bordered by a scalloped membrane, as the coots.

PINNA'TIPEDS, *Pinnatipedia*. (Lat. pinna, *a fin*, and pes, *a foot.*) A term applied by Temminck to an order of birds comprehending those which have the digits bordered by membranes.

PI'NNIPEDS, *Pinnipedes*. The name of a section of crabs (Brachyurous Decapod Crustaceans), in which are comprehended those that have the last pair of feet, if not more, terminated by a flattened joint fitted for swimming.

PI'NNOTHERES. (Gr. πιννοθηρης, from Lat. pinna, and Gr. θηραω, *I pursue.*) A small parasitic species of crab, which takes up its abode in the shell of the *pinna* and other bivalves.

PINT. A measure of capacity, being the eighth part of a gallon. *See* MEASURES.

PIO'NEERS, in the Military Art, are certain soldiers, in all infantry and cavalry regiments, whose business it is to clear the road before an army, to sink mines, and throw up works and fortifications. Pioneers are provided on a march with hatchets, axes, spades, pickaxes, and all other necessary implements.

PIPE. A wine measure, usually containing 105 (very nearly) imperial, or 126 wine gallons. Two pipes, or 210 imperial gallons, make a tun. But, in practice, the size of the pipe varies according to the description of wine it contains. Thus, a pipe of port contains 138 wine gallons, of sherry 130, of Lisbon and Bucellas 140, of Madeira 110, and of Vidonia 120. The pipe of port, it is to be observed, is seldom accurately 138 gallons, and it is usual to charge what the vessel actually contains.

PIPE CLAY. A species of clay, abounding in Devonshire and other parts of England, employed in the manufacture of various sorts of earthenware.

PIPERA'CEÆ. (Piper, one of the genera.) A natural order of shrubby or herbaceous Exogens, inhabiting the hotter parts of the world. According to Blume and Richard they are monocotyledonous; but that they are really dicotyledonous is proved by their medullary rays, articulated leaves, and two-lobed embryo. They are closely related to *Polygonaceæ*, *Saururaceæ*, and *Urticaceæ*, from all of which they are distinguished by obvious characters. Common pepper represents the ordinary property of this order. The cubebs of the shops is the produce of the *Piper cubeba* and *caninum;* betel, an acrid stimulating substance, much used for chewing by the Malays, is obtained from *Piper betel* and *siriboa*. Black pepper is the unprepared fruit of *Piper nigrum*, and white pepper is the same deprived of its pulpy covering. Long pepper consists of the half-ripe flower-heads of *Piper longum* and *chaba*.

PI'PERIN. A white crystallizable substance extracted from black pepper. It is tasteless, and free from pungency, the acrimony of pepper residing in a peculiar fixed oil.

PI'RACY. (Gr. πειρατης; from πειρα, *an attempt.*) In Law, an offence which consists in the commission of those acts of robbery and depredation upon the high seas which, if committed on land, would have amounted to felony there. By the statutes 11 & 12 W. 3. c. 7. and 6 G. 1. c. 19., piracies committed on the sea or in haven, &c., where the admiral has jurisdiction, may be tried at sea or on land, in his majesty's islands, &c., by commissioners under the great seal appointed for that purpose, who may commit the offenders, and call a court of admiralty for the purpose of the trial. By the same statutes various acts are enumerated as amounting to piracy, and aiders and abettors of pirates are declared accessaries, punishable as principals. By subsequent enactments, acts of trading with pirates, and acts of hostility committed by natural-born subjects against his majesty's subjects under colour of a foreign commission, are declared piracy. In the realm of England, felonies, robberies, and murders, committed by pirates, are triable under 28 H. 8. c. 15. by the king's commission of oyer and terminer, as if the offences had been committed on land. (See as to the pirates of antiquity, the *Mem. de l'Ac. des Inscr.* vol. xii.)

Piracy is also frequently used to signify any infringement on the law of copyright. It is extremely difficult to lay down any general principle on which to decide as to what is and what is not piracy. Generally it is held, that one writer may borrow the ideas or theories of another; but that he must dress them up and explain them in a different way, and in his own language. This, however, is often done so as merely to evade the law; and it were well, in order to make greater attention be paid to originality, were the law as to piracy less lax than it is at present. (See as to the existing law of piracy, the art. "Copyright—Books," in *Com. Dict.*)

PISALPHA'LTUM. Mineral pitch; an indurated bitumen.

PI'SCES. (Lat. pisces, *a fish.*) The name of the fourth great subdivision of Vertebrate animals, or the class of fishes characterized by a branchial respiration, a bilocular heart, and a covering of scales. The nasal cavities do not communicate with the mouth, but have only external apertures. *See* Ichthyology.

Pi'sces. (The Fishes.) One of the twelve zodiacal constellations, the twelfth in order from Aries. *See* Constellation, Zodiac.

PISCIS AUSTRALIS. (The Southern Fish.) One of Ptolemy's 48 constellations, in the southern hemisphere. The brilliant star Fomalhaut, of the first magnitude, belongs to this constellation.

PISCIS VOLANS. A small modern constellation of the southern hemisphere, formed by Bayer. It is situated on the antarctic circle.

PISÉ. (Fr.) In Architecture, a species of wall constructed of stiff earth or clay, carried up in moulds, and rammed down as the work is carried up.

PISI'DIUM. (Lat. pisum, *a pea.*) A genus of fresh water Gastropods; so named on account of the resemblance of the shell to a small pea. Many of the species are British; as *Pisidium obtusale*, which may be found in the New River; *P. pusillum*, *P. nitidum*, *P. pulchellum*, &c.

PI'SOLITE. (Gr. πισον, and λιθος, *peastone.*) A concretional carbonate of lime. The concretions generally contain a central grain of sand.

PISTA'CHIA or PISTA'CHIO NUTS. (Ger. pistachen; Du. pistasjes; Fr. pistaches; It. pistacchi, fastucchi; Sp. alfocigos; Lat. pistaciæ.) The fruit of the *Pistachia vera*, a kind of turpentine tree. It grows naturally in Arabia, Persia, and Syria; also in Sicily, whence the nuts are annually brought to us. They are oblong and pointed, about the size and shape of a filbert, including a kernel of a pale greenish colour, covered with a yellowish or reddish skin. They have a pleasant, sweetish, or unctuous taste, resembling that of sweet almonds; their principal difference from which consists in their having a greater degree of sweetness, accompanied with a light grateful flavour, and in being more oily. Pistachias imported from the East are superior to those raised in Europe.

PISTI'LLUM. The organ which occupies the centre of a flower, within the stamens and disk (if the latter be present). It is distinguished into three parts: an upper or stigma, a lower or ovarium, and a central part or style. It is the female organ of the flower, and contains the ovules or young seeds within the ovary.

PISTOLE. A gold coin common in many parts of Germany, equivalent to about 8*s*. 6*d*. sterling.

PI'STON. In Machinery, a short cylinder of wood or metal, which fits exactly the cavity of a pump or barrel, and works up and down in it alternately. Two sorts of pistons are used in pumps: one hollow, with a valve, used in the sucking pump; and the other solid, which is employed in the forcing pump. *See* Pump.

PIT. *See* Shaft.

PITCH. (Fr. picts.) In Music, the degree of acuteness or graveness of a note.

Pitch. (Germ. pech.) The same as Asphalt and Bitumen, which see.

Pitch. The residuum which remains after boiling tar in an open iron pot, or in a still, till the volatile matter be driven off. It is most extensively used in shipbuilding.

PITCHBLENDE. A mineral found in Saxony; it is a compound of the oxides of uranium and iron.

PITCH OF A ROOF. In Architecture, the inclination of the sloping sides to the horizon. It is usually designated by the ratio of its height to its space.

PI'TCHSTONE. A silicious mineral, the fracture of which resembles that of pitch or resin. It is of various colours.

PITCOAL. *See* Coal, and Geology.

PITH. A cylindrical or angular column of cellular tissue, arising at the neck of the stem of a Dicotyledonous plant, and terminating at the leaf-buds, with all of which, whether they are lateral or terminal, it is in direct communication. It forms the centre of a stem, and is covered over by the wood. Its use is to act as a reservoir of nutritious matter for the young leaves when first developing.

PITHE'CUS. (Gr. πιθηκος, *an ape.*) The subgeneric name of the orang-utan; *Pithicus satyrus*, Geoff.

PITOT'S TUBE. In Hydraulics, an apparatus, so called from the name of its inventor, for measuring the velocity of a stream, or of a body moved through stagnant water. A tube open at both ends is bent into two unequal branches at right angles to each other. It is then placed in the stream, the longer branch in a vertical position, and the shorter turned round so that the water enters directly into the orifice, which should be somewhat contracted. When thus placed, the water enters the tube with the velocity of the stream, and the pressure causes it to rise in the upright branch of the tube to the height from which it must have fallen in order to acquire this velocity. The height to which the water rises in the tube is measured by placing a graduated rod in the tube of such specific gravity as to float on the water; or if the tube is of glass, the height may be measured externally. The corresponding velocity is obtained from the formula $v = \sqrt{(2\,g\,h)}$; where v denotes the velocity, g the accelerating force of gravity, and h the height to which the water rises in the tube, all expressed in units of the same denomination. The result is tolerably accurate, except when the velocity is small; but the effect is somewhat diminished by the friction on the tube.

PI'TTACAL. (Gr. πιττα, *pitch*, and καλλος, *ornament.*) A fine blue substance, obtained by the action of a solution of baryta upon the heavy oil of tar.

PITUI'TARY GLAND. A gland situated within the cranium, between a fold of the *dura mater*, in the *sella turcica* of the sphenoid bone.

PITUI'TARY MEMBRANE. The mucous membrane of the nose.

PITYRI'ASIS. (Gr. πιτυρον, *bran.*) A cutaneous disease consisting of irregular scaly patches, unattended by

inflammation. When it affects infants, it is called *dandriff.* A similar exfoliation of the cuticle in reddish patches is not uncommon in adults. Soap and water, and mild cooling lotions, or very weak nitro-muriatic lotion, are the best applications.

PIU. (Ital.) In Music, a word frequently prefixed to another to increase the strength of its meaning; as *più allegro*, a little quicker.

PI'VOT. (Fr.) In Military language, that officer or soldier upon whom the different wheelings are made in the various evolutions of the drill, &c.

Pivot. In Mechanics, the extremity of the axle about which a body revolves.

PLACA'RD. (Said to be from the Greek πλαξ, *a tablet.*) A writing affixed to a wall, post, &c. in a public place, is commonly so called; and as this was in ancient times the common mode of publishing proclamations and edicts, and also of giving notoriety to libels and seditious advertisements, the word is not uncommonly used in early modern writers in both these senses.

PLACE'NTA. (Gr. πλακους, *a cake.*) The afterbirth. In the human subject it is a single subcircular, flattened, and lobulated organ, composed of the capillary extremities of the fœtal hypogastric arteries and umbilical vein, and of a fine cellular structure, which receives the maternal blood from the tortuous uterine or decidual arteries.

The placenta forms a single lobe in the New World monkeys, the bats, the Insectivora, and the Rodentia. It surrounds the fœtus like a broad hoop in the Carnivora. It is bilobed in the Old World monkeys; and subdivided into many separate lobes, called cotyledons, in the true Ruminantia. The placenta is replaced by a diffused vascular villosity of the chorion in the *Camellidæ*, the ordinary Pachyderms, and the Cetacea. The placenta is absent and the chorion ceases to be vascular in the Marsupialia.

Place'nta. In Botany, a copious development of cellular tissue, formed at some point of the inside of a carpellum, and out of which the ovules or young seeds arise.

PLACENTA'LIA. The name of that primary division of the class Mammalia which includes the orders that have either a placenta or a vascular chorion, by which the fœtus is attached to the parietes of the uterus.

PLA'CITA (Lat.), in the Middle Ages, were public courts or assemblies, in which the sovereign presided when a consultation was held upon the affairs of the state. They were termed "Generalia Placita," because "generalitas universorum majorum tam clericorum quam laicorum ibidem conveniebat." The same custom appears to have existed in France, with a slight modification. According to the *Black Book* in the Exchequer, lib. ii. let. 13., this term was also applied to penalties or fines.

PLA'GAL MELODIES. (Gr. πλαγιος, *oblique.*) In Music, such as have their principal notes lying between the fifth of the key and its octave or twelfth.

PLA'GIARISM. (From the Latin legal term plagium, which signified the offence of stealing a slave, or kidnapping a free person into slavery.) A plagiary, in the modern sense of the word, is one who borrows without acknowledgment, in literary composition, the thoughts or words of another; and the theft itself is styled plagiarism.

PLA'GIOSTOMES, *Plagiostoma.* (Gr. πλαγιος, *transverse*, and στομα, *a mouth.*) A tribe of Cartilaginous fishes, comprehending all those which have the mouth situated transversely beneath the snout. Also the name of a genus of Univalve Mollusks.

PLAGUE. "A typhus fever eminently contagious, and attended by excessive debility: at an uncertain period of the disease carbuncles or buboes ensue." This is Cullen's brief but correct definition of this horrible disease. The best account of the plague, and of its ravages, is to be found in Heberden's work on the *Rise and Decline of Disease.* See also the article Cholera in this work.

PLAID. A striped or variegated cloth much worn by the Highlanders of Scotland, forming a prominent part of the national costume, and indicating, by the variety of its patterns, the different Scottish clans.

PLAIN CHANT. In Music, a term in ancient ecclesiastical music to signify the chief melody, which was confined within the natural sounds of the scale.

PLAINS. In Geography, the general term for all those parts of the dry land which cannot properly be called mountainous, and which compose by far the greater part of the earth's surface. Plains have different physical appearances according to their geographical position, and the peculiar characteristics of each have procured for them different names; thus we have the steppes of Asia, the deserts of Africa, the pampas of South America, and the prairies or savannahs of North America. See these different terms.

PLAN. (Lat. planus.) A drawing of something on a plane.

Plan. In Architecture, an horizontal section of the walls, partitions, staircases, &c. of a building, showing the distribution of the ground plot.

PLANA'RIA. (Lat. planus, *flat.*) The name of a genus of *Sterelmintha*, or Parenchymatous Intestinalia of Cuvier, which do not inhabit the interior of animal bodies, but closely resemble, in their organization, the parasitic species of Trematode Entozoa. They lead from this order to the Suctorious Anellides, or leeches.

PLANE, in Geometry, is a surface without curvature; or it is a surface such that if any two points whatever in it be joined by a straight line, the whole of the straight line will be in the surface.

PLANE PROBLEM, in Geometry, is a problem which can be solved by the intersections of straight lines and circles, without the aid of the conic sections or any of the higher curves. Such problems as require the construction of the conic sections were called, by the ancient geometers, *solid problems.*

PLANE SAILING, in Navigation, is the art of determining the ship's place, on the supposition that she is moving on a plane, or that the surface of the ocean is plane instead of being spherical. On account of the magnitude of the terrestrial radius, this supposition may be adopted for short distances without leading to great errors; and it affords great facilities in calculation, for the place of the ship is found by the solution of a right-angled plane triangle. The part of the meridian between the ship and the parallel of latitude of the place whence she departed forms the perpendicular of the triangle; the distance on the parallel between the place of departure and the foot of the perpendicular is the base of the triangle (technically called the departure); and the distance sailed is the hypothenuse. The angle at the ship is called the course, and the other acute angle the complement of the course. Now, of these four things, the perpendicular, the departure, the distance sailed, and the course, any two being given, the triangle can be laid down on the chart, and all the other parts of it found. See Navigation.

PLA'NET. (Gr. ἀστηρ πλανητης, *wandering star.*) The name given by the ancient Greeks to a few bright and conspicuous stars which are constantly changing their apparent situations in the celestial sphere, and thus appear to *wander* among the constellations. The modern discovery of satellites and periodic comets has rendered it necessary to adopt a more precise definition, in order to individualize the class of objects to which the term is applied; and accordingly modern astronomers understand by the term planet a body which, in a telescope of sufficient power, exhibits a round and well-defined disk, and which revolves about the sun in an elliptic orbit, not differing very greatly from a circle.

The number of planets, including the earth, at present known to belong to the solar system, is eleven. Five of them — namely, Mercury, Venus, Mars, Jupiter, and Saturn — have been known from the earliest ages of astronomy; Uranus was discovered by Sir William Herschel in 1781; Ceres by Piazzi, at Palermo, on the first day of the present century; and the discovery was soon followed by that of Juno, Pallas, and Vesta. The last four are never visible to the naked eye; under favourable circumstances Uranus may be discerned without a telescope; and Mercury, though it appears as a large star, is seldom to be seen (in our climates at least), in consequence of its proximity to the sun.

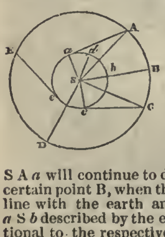
Of the apparent Motions of the Planets. — On watching the motions of any of the conspicuous planets for a few days or weeks, their change of position among the fixed stars becomes sufficiently apparent, even without the aid of an instrument to measure their relative distances. Their paths deviate little from that followed by the sun in his apparent annual revolution through the heavens; but their motions are exceedingly irregular. Sometimes they advance rapidly, then relax in their speed, come to a stop, and then move for a while in an opposite direction. Through the most considerable part of their orbits they move like the sun from west to east, in opposition to the apparent diurnal motion; their course is then said to be *direct.* When it lies in the opposite direction, their motion is *retrograde;* and between each change from the one direction to the other, they remain for a few days *stationary.* On the whole, however, the direct motion prevails, and the planets make the entire circuit of the heavens. These phenomena, which are called the *stations* and *retrogradations* of the planets, may be exhibited in the following manner:—

Let E C represent the ecliptic developed on a plane surface: the path of a planet, found by laying down its observed positions with reference to the ecliptic from day to day, will present the appearance of the zigzag line P Q R S. From P to Q the motion is direct, but becomes slower as the planet approaches to Q. At Q it is stationary; from Q to R retrograde; at R again stationary; from R to S direct, and so on. Such is the general character of the apparent motion; but the arcs and times of retrogradation differ greatly in respect of the different planets.

Mercury and Venus exhibit phenomena peculiar to themselves, inasmuch as they never appear in the opposite quarter of the heavens to the sun, but oscillate about the sun from side to side; the oscillations of the former being much quicker, and performed in a much smaller arc than those of the latter. The distance of Venus from the sun never exceeds an arc of about 47°; and at its greatest distance the planet does not continue above the horizon more than about 3 hours after sunset. Its brilliancy, however, is such, that it may frequently be seen in the morning several hours after the sun has risen. Mercury never recedes farther from the sun than 28° 20′, and does not appear above the horizon more than 1 h. 40 m. after sunset, or before sunrise. For these reasons, Mercury and Venus were regarded by some of the ancient astronomers as satellites of the sun, and supposed to describe orbits round that luminary. The other planets, Mars, Jupiter, and Saturn, being frequently seen in opposition to the sun, and at all different distances from it, were supposed to have independent motions.

In order to explain and represent the apparent motions of the planets, the ancient astronomers had imagined various hypotheses, of which the most celebrated is that of epicyles and deferents, invented by the geometer Apollonius; and adopted by Ptolemy, after whom it was called the Ptolemaic system of the universe, and implicitly believed in during many centuries. According to this hypothesis, each planet moves uniformly in a small circle, called the *epicyle*, the centre of which is carried along, with a uniform motion, in the circumference of another large circle, called the *deferent*, which has the earth at its centre. (*See* EPICYCLE.) By supposing the velocity of the planet in its epicycle to be greater than that with which the centre of the epicycle is carried along the deferent, and by assigning proper relations between the lengths of the radii of the epicycles and deferent circles (their absolute lengths are immaterial), the apparent geocentric motions may be represented with all the exactness of which the ancient observations admitted. Ptolemy placed the earth at the centre of the universe, and nearest to it the moon. Next to the moon was Mercury, then Venus, then the sun; after which followed in order Mars, Jupiter, and Saturn; the distances of the three last being arranged according to their respective periods of revolution; it being natural to suppose that those which required the longest time to complete their periods must revolve in the widest circles. At the present day, and familiar as we now are with the true nature of the celestial motions, this complicated system appears abundantly absurd; but it should be recollected that Ptolemy possessed no means of forming any accurate notions of the distances of the planets: he was unacquainted with the alternate increase and diminution of their apparent diameters, with the phases of Venus, and all the other information afforded by the telescope; in short, he knew of no phenomenon which could not be reconciled to his theory; and he does not appear to have ever regarded his system of epicycles and deferents in any other light than a mere hypothesis, by means of which the celestial motions could be reduced to calculation.

All the apparent irregularities of the planetary movements are got rid of at once by referring them to the sun as a centre, instead of the earth. This great step in theoretical astronomy was made by Copernicus, who first demonstrated that all the phenomena were explicable in the simplest manner by supposing the sun to be placed at the common centre of the planetary motions, and ascribing to the earth a double motion; namely, a diurnal rotation about its axis, and an annual revolution about the sun. On this hypothesis, the truth of which has been established by a multitude of different considerations, the stations and retrogradations of the planets, and all the geocentric appearances which so much perplexed the ancient astronomers, become simple consequences of relative motion. In order to illustrate this, let us consider the appearances which must result from the combined motions of the earth and an *inferior* planet; that is, a planet nearer to the sun than the earth is. Let S be the sun, A B C D the orbit of the earth, and *a b c d* that of Mercury, both moving in the same direction, or in the order of the letters. Suppose A to be the position of the earth, and *a* that of Mercury at its greatest eastern elongation: the line A *a* will be a tangent to the orbit at *a*. As the earth advances from A towards B, and the planet from *a* toward *b*, the angle of elongation S A *a* will continue to diminish, till the earth arrives at a certain point B, when the planet is at *b* in the same straight line with the earth and the sun, the angles A S B and *a* S *b* described by the earth and the planet being proportional to the respective mean angular motions. In this situation the planet is said to be at its *inferior conjunction*.



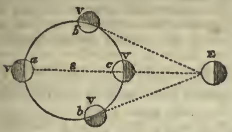
When the earth has passed B, the planet, advancing with a more rapid angular motion, will begin to appear on the western side of the sun, and the angle of elongation continue to increase, till the planet arrives at *c*, and the earth at C, where the visual line is again a tangent to the orbit. The angle of elongation has now attained a second time its maximum value, and from this point will continue to decrease, till it vanishes altogether when the earth arrives at D and the planet at *d*, the three points D S and *d* being in the same straight line. The planet is now at its *superior conjunction*, and *beyond* the sun. Soon after this the planet reappears on the eastern side of the sun; and the angle of elongation continues to increase till the planet comes round to *e*, and the earth arrives at E, where the line E *e* is again a tangent to the orbit. The earth, the planet, and the sun have now precisely the same relative situations in respect of each other as they had when the earth was at A and the planet at *a*, so that the series of changes will here recommence and proceed in the same order as before. The intervals after which these phenomena occur may be easily computed from a knowledge of the periods of revolution of the earth and planet, and of the proportion of the radii of their respective orbits, which is, moreover, known immediately from the observed angle of greatest elongation, S A *a*; for, since S *a* A is a right angle, we have S A to S *a* as radius to the cosine of S A *a*: that is, the radius of the planet's orbit is equal to the the radius of earth's orbit multiplied by the cosine angle of greatest elongation.

From the preceding figure, it is easy to see how the phenomena of the stations and retrogradations must arise. At the point *b*, where the planet is at its inferior conjunction, the earth and planet are both moving in the same direction; but, as the planet is moving faster, it will leave the earth behind it; and the apparent motion, as seen from the earth, will be the same as if the planet stood still, and the earth moved in a contrary direction, with a velocity equal to the difference of their relative motions. The apparent motion of the planet is therefore contrary to the apparent motion of the sun, and consequently retrograde. At the superior conjunction *d*, the planet and earth are moving in opposite directions in respect of the line D *d*; the relative motion is therefore the same as if the planet stood still, and the earth was moving in its proper direction with a velocity equal to their united motions: the apparent motion of the planet in this situation is therefore direct. At the points of greatest elongation, *a* and *c*, the planet is moving in the direction of the line of vision, A *a* or C *c*, and the earth perpendicular (nearly) to that line; the apparent motion of the planet at those points is therefore direct. But since it is direct at *a* and *c*, and retrograde at *b*, there must be a point between *a* and *b*, and another between *b* and *c*, where the apparent motion is neither direct nor retrograde, that is, where the planet appears stationary. The problem of determining the stationary points is one of pure geometry, and very easily resolved when the orbits are supposed to be circular, and the motion uniform; but, in the case of elliptic orbits and unequable motion, it is considerably more complicated. The stationary points of Mercury are variable from 15° to 20° of elongation from the sun; those of Venus are about 29°. Mercury continues to retrograde about twenty-two days, Venus about forty-two.

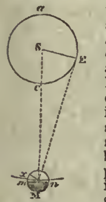
The apparent motions of the *superior* planets, or those which are at a greater distance from the sun than the earth is, are explained with equal facility. As their orbits embrace that of the earth, they are not confined to certain limits of elongation from the sun, but appear at all distances from it, even in the directly opposite quarter of the heavens. When they are in *conjunction*, they are situated beyond the sun, in the same straight line with the sun and earth; and when the earth comes between them and the sun, they are said to be in *opposition*. All the superior planets, when in opposition, and for some time before and after, appear to have a retrograde motion; but the extent of the arc of retrogradation, the time during which the motion is retrograde, and the velocity, are very different in respect of the different planets. Mars continues to retrograde about 73 days, Jupiter 121, and Saturn 138.

Phases of the Planets. — It is a necessary consequence of the Copernican theory, that the planets, supposing them to be, like the earth, round opake bodies illuminated by the sun, must exhibit phases like the moon, according to the angles under which the illuminated half of their surfaces is seen from the earth. When viewed through the telescope, this is found to be the case with Mercury and Venus, and to a certain extent also with Mars; and the appearance of the phase is in every case exactly such as is determined *a priori*, on the supposition that the planet is seen by the reflected light of the sun. Let S be the sun, E the earth, and V Venus, in different positions of her orbit. When the planet is at its superior conjunction *a*, the whole of its illuminated surface is seen from the earth, and it consequently exhibits a round disk. At the points of greatest elongation, *b* and *b*, one half only of the illuminated hemisphere is visible, and it therefore

appears half-mooned at these points. At c, the inferior conjunction, the dark side is turned directly to the earth, and it is consequently invisible. Between a and b, the planet will therefore appear gibbous (*i. e.* more than the half full); and between b and c it will appear in the form of a crescent, like the moon in its first or last quarter. The phases of Mercury are precisely similar.



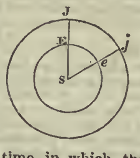
With respect to the superior planets, the absence of phases is a necessary consequence of their great distances from the sun in comparison of the earth's distance. Let S be the sun, E the earth, and M Mars. It is evident that, as the earth goes round its orbit, the smallest portion of the enlightened hemisphere, $m\ x\ n$, will be visible when the earth is at E, or in such a position that the angle S E M is a right angle. Suppose a line, therefore, to be drawn from the centre of the planet perpendicular to E M, and intersecting the surface in x, the visible surface will be contained between x and n, so that the disk will appear to be gibbous, but can never appear as a crescent. These phenomena prove in the most convincing manner that the planets are opake spherical bodies, deriving their light from the sun.



Distances and Periodic Times of the Planets. — Practical astronomy furnishes various methods of determining the distances of the planets from the sun in terms of the earth's distance, and the times in which they complete their revolutions. It has already been stated, that the distances of Mercury and Venus may be compared with that of the earth by observing the angle of greatest elongation. In the case of a superior planet, an approximation to the relative length of the *radius vector* (the line which joins the planet with the sun) may be obtained by observing the angular velocity of its apparent retrogradation about the time when it is in opposition. Thus, conceive E e to be a small portion of the earth's orbit described in a given interval of time, a day, for example, and M m to be the corresponding portion of the orbit of Mars described in the same interval, the planet being near the opposition. Join $e\,m$, and draw $e\,n$ parallel to SM. As seen from e, Mars will appear to have retrograded from n to m; therefore the angle $n\ e\ m$ is given by observation, and consequently its complement $m\ e$ E becomes known (for the arc E e, being very small, may be regarded as a straight line). Now, in the triangle e S E, right-angled at E, the angle at S is given, being the angle described by the radius vector of the earth in the given interval; consequently the angle S e E becomes known, and hence also S $e\ m$. Supposing, therefore, the periodic time of Mars to be known, the arc M m, or the angle M S m, will be given; and therefore m S e, which is its difference from E S e, becomes known. In the triangle S $e\ m$, we have therefore given the two angles S $e\ m$, and e S m, and consequently also the third angle $e\ m$ S, whence the triangle is given in species, and the ratio of S e to S m is determined. But S m is the distance of Mars from the sun, which, therefore, is determined in terms of the radius vector of the earth.

The method of finding the planet's distance, which has just been described, requires that the periodic time be previously known. There are various methods of determining the periodic time, independently of a knowledge of the distance of the planet from the earth. One is to observe the times at which the planet is in either of its nodes, *i. e.* when it passes through the plane of the ecliptic. As the orbits are all inclined to the ecliptic, and have the sun nearly at their centres, they are intersected by the plane of the ecliptic in two opposite points, which are called the *nodes*. Now it is easy to ascertain by observation when a planet is in its node; for, as it then passes from the one side of the ecliptic to the other, from the north to the south side, for example, we have only to convert the observed right ascensions and declinations into longitudes and latitudes, and the change from north to south latitude between two successive observations will indicate that the planet has passed its node in the interval; while a simple proportion, grounded on the quantity of its motion in latitude, will fix the precise hour and minute at which it was in the ecliptic. The interval between two successive passages of the planet through the same node differs from the *sidereal* period, or the interval which the planet occupies in returning to the same point of the heavens, or the same *star*, as seen from the centre of the sun, by a very small quantity, depending on a minute motion of the node, and which in a general view of the subject may be disregarded.

Another and more convenient method of finding the period of a superior planet consists in determining, from the observations of a few consecutive days, the exact time at which it is in opposition to the sun. At this instant the longitude of the planet is 180°, and on the day of the opposition it passes the meridian twelve hours after the sun. The interval between two successive returns to the opposition is the *synodic* period of the planet; this differs very considerably from the sidereal period, but the latter is easily deduced from it. Let E and J be the positions of the earth and Jupiter, when Jupiter is in opposition. The next opposition will take place after the earth has made a complete revolution, together with a certain arc E e, which we shall call x, corresponding to Jupiter's angular motion in the interval. Now the number of days between the two oppositions, or the synodic period, is known: call this $365 + t$; then the time in which the arc E e or x has been described becomes t days. We have therefore $365 : t :: 360° : x$; whence x, or the angle J S j, is known. But, if p denote the sidereal period, we shall have $x : 360° :: t : p$, and therefore $p = \frac{360\,t}{x}$. On account of the orbits not being exactly circular, these intervals are not quite equal; but by taking the average of a considerable number of observed oppositions, the inequalities disappear, and the mean synodic periods (and consequently the sidereal periods) are obtained with the utmost accuracy.



The following table exhibits the mean sidereal periods of the planets, and their mean distances from the sun, in terms of the mean distance of the earth from the sun being supposed equal to unity. (*Baily's Astronomical Tables.*)

Planet.	Mean Sidereal Period.	Mean Distance from the Sun.
	Days.	
Mercury	87·969258	0·387098
Venus	224·700787	0·723332
The Earth	365·256361	1·000000
Mars	686·979646	1·523692
Vesta	1325·743100	2·367870
Juno	1592·660800	2·669009
Ceres	1681·393100	2·767245
Pallas	1686·538800	2·772886
Jupiter	4332·584821	5·202776
Saturn	10759·219817	9·538786
Uranus	30686·820830	19·182390

Relations between the Periods and Distances. — On comparing the columns of the above table, the idea of a certain relation between the periods and distances cannot fail to suggest itself, as they both increase in a tolerably regular progression (the four small planets between Mars and Jupiter being accounted as one), though the periods increase in a much more rapid proportion than the distances. Jupiter, for example, is five times more distant from the sun than the earth is, but his period is nearly twelve times that of the earth. Kepler, the great founder of physical astronomy, undertook to investigate the analogy; and, after a most laborious comparison of the numbers (and their various powers) representing the periodic times and the mean distances of the six planets known in his age, discovered this most remarkable law: — "That the squares of the periodic times of any two planets are to each other in the same proportion as the cubes of their mean distances from the sun." (*See* KEPLER'S LAWS.) Taking, for example, the earth and Mars, whose periods are respectively 365·256 and 686·979 days, and distances in the proportion of 1 and 1·5237, it will be found that $(365·256)^2 : (686·979)^2 :: 1 : (1·5237)^3$, very nearly. Nor is this merely an empirical relation, deduced from observed facts, but not referable to any known cause; on the contrary, it is a necessary result of the law of gravitation, and pregnant with important consequences. From its being observed in the planetary system, it follows that all the planets are bodies of the same kind as the earth, and that they are all acted upon in the same manner by the solar attraction (modified only by the distance), which alone determines their periods, and retains them in their orbits.

A curious relation of the numbers which express the relative distances of the planets from the sun was discovered by M. Bode, an astronomer of Berlin. Let the number 10 be assumed to represent the distance of the earth from the sun; then the distances of the other planets may be expressed in round numbers as follows: —

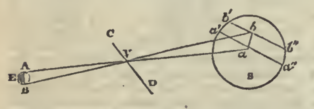
Mercury	$4 = 4$
Venus	$7 = 4 + 3·2^0$
The Earth	$10 = 4 + 3·2^1$
Mars	$16 = 4 + 3·2^2$
The four New Planets	$28 = 4 + 3·2^3$

Jupiter	- - - -	$52 = 4 + 3 \cdot 2^4$
Saturn	- - - -	$100 = 4 + 3 \cdot 2^5$
Uranus	- - -	$196 = 4 + 3 \cdot 2^6$

It had been conjectured by Kepler that an unknown planet must exist circulating between the orbits of Mars and Jupiter, a conjecture which was strangely verified by the discovery of four planets circulating in that region, nearly in equal periods, and at equal distances from the sun, and exactly in the place where a planet was wanting to fill up the above progression. The progression is, however, purely empirical, and not even very accurate; yet it agrees so well, on the whole, with the actual distances of the planets, that one can scarcely help thinking it must be connected in some manner with the essential constitution of the planetary system.

Real Dimensions of the Planetary Orbits.— Hitherto we have spoken of the distances of the planets from the sun only in relation to the sun's distance from the earth; but it is interesting to determine what these distances actually are in terms of some measure with which we are familiarly acquainted. In consequence of Kepler's law of the relation between the periods and distances, if the real dimensions of any one orbit have been ascertained, those of all the other orbits will be found immediately when the periodic times of the planets are respectively known. In fact, the dimensions of the orbits having been already stated in terms of that of the earth, it is only necessary to find the earth's distance from the sun, in order to find the respective distances of all of them. Now, to find the earth's distance from the sun is the same thing as to find the sun's horizontal parallax, that is, the angle which the radius of the earth would subtend if seen from the sun; for the determination of that angle gives the relation between the earth's distance and its semidiameter, which is known from the actual measurement of degrees of the terrestrial meridian. Of the various methods which astronomers possess of determining the sun's horizontal parallax, the most accurate is that which depends on observations of the transits of Venus over the sun's disk; a phenomenon, however, of very rare occurrence, so that the method can very seldom be practised.

When Venus is at her inferior conjunction, and at the same time very near one of her nodes, the planet will be projected on the disk of the sun; and through the effect of her proper motion, combined with that of the earth, will be seen as a black spot to pass over, or *transit*, the solar disk, describing a chord which will be referred to different positions on the disk by observers stationed at different points on the earth's surface. Let E be the earth, V Venus, S the sun, and C D a portion of Venus's orbit, described while she is transiting the sun's disk.



Suppose A and B to be the two opposite extremities of the earth's diameter which is perpendicular to the ecliptic: a spectator at A would see the centre of Venus projected on the sun's disk at *a*, and describing in her successive positions the chord *a′ a a″*; while a spectator placed at B would, at the same instant, see her projected on the disk at *b*, and describing the chord *b′ b b″*. Now it is evident that if there be any means of measuring the distance between the two chords *a′ a″* and *b′ b″*, or the line *a b*, that distance will give the sun's horizontal parallax; for the two triangles A V B and *a* V *b* being similar, *a b* is to A B as *a* V to A V, or as the distance of Venus from the sun is to the distance of Venus from the earth. But the relative distances of the earth and Venus from the sun are known; therefore the ratio of *a* V to A V is known, and consequently that of *a b* to A B. This ratio is that of 68 to 27, or 2½ to 1 (very nearly); therefore the distance *a b* as seen from the earth is 2½ times greater than A B as seen from the sun, or, which is the same thing, equal to 5 times the sun's horizontal parallax. The whole difficulty of the problem, therefore, consists in determining the distance of the two chords *a′ a″* and *b′ b″*, or their relative positions on the sun's disk, from which their distance can be deduced. One of the best ways of accomplishing this is to note, with great accuracy, the instants at which Venus enters and emerges from the solar disk, so as to obtain the exact time occupied in the transit; for, the relative motion of Venus being accurately known, the time occupied in the transit gives the length of the chord described; and the sun's apparent diameter being also known, the arcs cut off by *a′ a″* and *b′ b″* are thus found, and the difference between the versed sines of those arcs is evidently the distance between the chords, or the line *a b*. The problem, however, is rendered much more complicated by the earth's rotation, and other circumstances here neglected, of which it is unnecessary to take account in a general explanation.

The last transit of Venus took place in 1769, and was the occasion of the first of the celebrated voyages of Captain Cook to Otaheite. It was observed at Otaheite, at Wardhus in Norway, at Cajaneburg, and Kola in Lapland; at Petersburg, Paris, California, Hudson's Bay, &c. The general result of all the observations gave the sun's horizontal parallax equal to 8·5776″. Hence, the sun's distance is given in terms of the earth's radius by the proportion

sin. 8·5776″ : radius : : radius of earth : sun's distance;

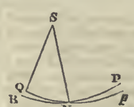
whence, on reducing the radius of a circle to seconds, we have the sun's distance $= \dfrac{360 \times 60 \times 60}{8 \cdot 5776 \times 2 \times 3 \cdot 14159} = 24047$ terrestrial radii. Assuming the earth's semidiameter (*see* EARTH) to be 4000 miles in round numbers, the sun's distance from the earth will therefore be 24047 × 4000 = 96,188,000, or about 96 millions of English miles.

This application of the transits of the inferior planets to the important purpose of determining the sun's distance from the earth was first pointed out by James Gregory, in his *Optica Promota*, published in 1663. Those of Venus recur after intervals of 113 years; but as Venus returns to her conjunction at nearly the same point of her orbit in about eight years, and the difference of her latitude at two successive conjunctions amounts only to 20′ or 24′, which is less than the sun's diameter, it will generally happen that two transits take place within eight years; the first before the planet has passed the node, and the second after the passage of the node. But three transits cannot take place within 16 years; hence, after two transits have occurred within 8 years, another cannot be expected before 105, that is, 113 — 8 years, and may not happen until after 121 years. The two last transits took place in 1761 and 1769; the two next will take place in 1874 and 1882; after which there will not be another till 2004. By reason of the small distance of Mercury from the sun, the difference between his horizontal parallax and that of the sun cannot be so accurately ascertained: and hence the transits of that planet, though of more frequent occurrence than those of Venus, cannot be employed with such certainty in determining the sun's parallax.

Having found the mean distance of the earth from the sun in terms of a known unit, the mean distances of all the other planets from the sun, the ratios of which to that of the earth were given above, may be expressed in the same terms. They are, in round numbers, as follows:—

		Miles.
Mercury	- - -	37,000,000
Venus	- - - -	68,000,000
The Earth	- - - -	96,000,000
Mars	- - - -	142,000,000
Ceres	- - - -	262,000,000
Jupiter	- - - -	485,000,000
Saturn	- - - -	890,000,000
Uranus	- - -	1,800,000,000.

Inclination and Nodes of the Planetary Orbits.— The planes of the planetary orbits are inclined to each other under different angles, and, in determining the circumstances of a planet's motion, one of the first steps to be taken is to fix the situation in space of the plane in which it moves. For this purpose, it is necessary to refer it to some other plane whose situation is assumed to be known. The plane of the ecliptic is that to which we naturally refer the bodies of the solar system, and the line of the equinoxes is taken as the origin of angular reckoning in that plane. Hence, to determine the position in space of the plane of a planet's orbit, we must determine its inclination to the ecliptic, and the position of the line in which it intersects the ecliptic with respect to the line of the equinoxes. Let S be the sun, P N R the orbit of of a planet, and *p* N Q the projection of that orbit on the plane of the ecliptic, intersecting the line of the equinoxes S Q in Q; then Q is the point from which the longitudes are reckoned, N is the node, S N the line of the nodes, or line in which the plane of the orbit intersects the ecliptic, the angle Q S N the longitude of the node as seen from the sun, and P N *p* the inclination of the orbit.



If R be supposed to be on the south side of the ecliptic, and P on the north side, and the planet's motion to be in the direction R P, then N is the *ascending* node. The place of the node is determined by observing the planet when its latitude is very nearly equal to nothing; and the equinoctial point Q being known, the *geocentric* longitude of the node (the angle formed by drawing straight lines from Q and N to the earth) is determined by observation; whence there are sufficient data for computing, by a trigonometrical process, the *heliocentric* longitude Q S N, and also the inclination P N *p*. The places of the nodes are not absolutely fixed. In consequence of the mutual attractions of the planets to each other, they have a slow retrograde motion in respect of the fixed stars. The inclinations are also subject to a slight variation, but so small as to amount at most to a few seconds in a century. Hence, in mentioning the longitudes of the nodes, and the inclin-

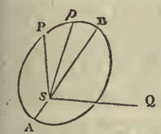
ations of the orbits, it is necessary to state the epoch to which the values refer. In the following table the values correspond to the 1st January, 1801; excepting those for Vesta, Juno, Ceres, and Pallas, which are referred to January 1. 1820:—

Planet.	Inclination.			Longitude of ascending node.		
	°	′	″	°	′	″
Mercury	7	0	9·1	45	57	30·9
Venus	3	23	28·5	74	54	12·9
Mars	1	51	6·2	48	0	3·5
Vesta	7	8	9·0	103	13	18·2
Juno	13	4	9·7	171	7	40·4
Ceres	10	37	26·2	80	41	24·0
Pallas	34	34	55·0	172	39	26·8
Jupiter	1	18	51·3	98	26	18·9
Saturn	2	29	35·7	111	56	37·4
Uranus	0	46	28·4	72	59	35·3

The ancients gave the name of *zodiac* to that zone of the heavens within which the planets were observed to move, and which, consequently, had a breadth of 14°, or twice the inclination of the orbit of Mercury. The inclinations of the four recently discovered planets being greater than that of Mercury, they go beyond the zodiac, and hence have been named the *extra-zodiacal* planets.

Figures of the Planetary Orbits.— When the inclination of a planet's orbit and the situation of the line of the nodes have been determined, the radius vector of the planet, at any instant, may be computed in terms of the sun's distance from the earth, from the planet's latitude and longitude found by a single observation. By computing, therefore, the values of its radius vector at a great many different points of the orbit, and laying down each on paper at the proper angle of elongation round the sun, the form of the orbit which the planet describes will be ascertained. A few observations of this sort will show that the radius vector varies in length, and, consequently, that the orbit is eccentric. This fact was known from the time of Hipparchus; but the true form of the planetary orbits was not discovered till Kepler found, by a laborious computation of the distances of Mars at its oppositions, from the observations of Tycho Brahe, that the orbit of that planet is an ellipse. He subsequently found the same thing to be true of the orbit of the earth, and of the other planets then known; and hence established the first of those important laws respecting the planetary motions which still go by his name, viz. that the orbits of al. the planets are ellipses, of which the sun occupies one of the foci. See Kepler's Laws.

The same observations which show the orbit to be an ellipse will also serve for the determination of its eccentricity, which is half the difference between its greatest and least distances. The only element which then requires to be known, in order to fix the path described by the planet in space, is the position of the orbit on its plane, or the situation of its transverse axis with respect to the line of the equinoxes. Let A P B be the projection of an orbit on the plane of the ecliptic, A B its transverse axis, and S Q the line of the equinoxes, S being the focus occupied by the sun. The point A is the *perihelion* of the orbit, and B the *aphelion;* the line A B is the line of the *apsides;* and the position of A B with respect to S Q will be known by means of one of the angles Q S A or Q S B, which are respectively the longitudes of these points. In modern tables, the angle Q S A, or *longitude of the perihelion*, is that whose value is given. The eccentricities of all the planets are subject to a very small secular variation; the line of the apsides is also in a state of continual but slow revolution, so that the perihelia are gradually shifting their places on the planes of the orbits. In the case of all the planets excepting Venus, the motion of the line of the apsides is direct; that is to say, it is in the same direction as the motion of the planet in its orbit. The perihelion of Venus, referred to the fixed stars, moves in a contrary direction. The following table shows the eccentricities and longitudes of the perihelia of the different planets; the epoch, as before, being January 1. 1801, for the old planets, and 1820 for the four new ones:—



Planet.	Eccentricity.	Longitude of Perihelion.		
		°	′	″
Mercury	0·205515	74	21	47
Venus	0·006861	128	43	53
The Earth	0·016784	99	30	5
Mars	0·093307	332	23	57
Vesta	0·089130	249	33	24
Juno	0·257848	53	33	46
Ceres	0·078439	147	7	31
Pallas	0·241648	121	7	4
Jupiter	0·048162	11	8	35
Saturn	0·056151	89	9	30
Uranus	0·046679	167	31	16

Motion of the Planets in their Orbits.— When the six elements of which numerical values have now been given, viz. the mean distance and periodic time, the inclination of the orbit and longitude of the node, the eccentricity and longitude of the perihelion, have been determined for each planet, it will be possible to compute the position of a planet in its orbit, provided we know the law according to which the planet moves at every point of the orbit, and also the instant of time at which it occupied any given point. The motion in the orbit is given by the second of Kepler's laws; viz. "The areas described by the radius vector are proportional to the times employed in describing them." Thus, if the planet has moved from A to P (see the preceding figure), or the radius vector S P has described the area A S P in the time t, and the area A S p in the time t'; then $t : t' :: $ sector P S A : sector p S A. The problem which proposes to find the point P, or the angle A S P (which is called the *true anomaly*), from the condition that the area A S P shall be to the whole ellipse as the given time in which A P is described is to the time of a whole revolution, is important in practical astronomy, and known by the name of Kepler's problem. See Kepler's Problem.

Magnitude and Rotation of the Planets.—When the planets are examined through powerful telescopes, they are seen to be round bodies, having measureable, and even considerable, apparent diameters. The distance of a planet being known, if the visual angle subtended by its diameter be measured by the micrometer, the real magnitude of its diameter will be discovered. In this manner it is found that all the planets are incomparably smaller than the sun, though some of them are vastly larger than the earth. The diameter of Jupiter is eleven times times greater than that of the earth, whence his volume is about 1280 times greater than the earth. That of Saturn is little less considerable. The surfaces of the larger planets are also seen to be diversified by dark patches or spots, from the attentive observation of which it is found that they resemble the earth in having a rotation about their own axes. Mercury, Venus, and Mars revolve about their axes in nearly the same time as the earth; Jupiter and Saturn in less than half that time. The four *new planets*, Vesta, Juno, Ceres, and Pallas, are so small and indistinctly seen that their diameters cannot be accurately measured, and their periods of rotation are unknown. Pallas, considered to be the largest of them, was supposed by Sir William Herschel to have a diameter of only 80 English miles. In the following table the true diameters and the volumes are given in terms of the diameter and volume of the earth, supposed to be unit:—

Planet.	Diameter.	Volume.	Sidereal Rotation.		
			hrs.	m.	sec.
Mercury	0·398	0·063	24	5	28
Venus	0·975	0·927	23	21	7
The Earth	1·000	1·000	24	0	0
Mars	0·517	0·139	24	39	21
Jupiter	10·860	1280·900	9	55	50
Saturn	9·982	995·000	10	29	17
Uranus	4·332	80·490	unknown.		

(For other particulars respecting the appearances and physical condition of the several planets, their masses, densities, &c., see the respective terms.)

The force which retains the planets in their orbits is the attraction of the sun; and, if they were acted upon by no other force, the laws of Kepler would be accurately observed, and the elements of their orbits would remain invariable. But each planet exercises an attracting force on every other, in consequence of which their motions, though principally obedient to the predominating influence of the sun, are affected by a number of forces of which the intensities and directions are perpetually changing. Hence all the elements of the orbits, their magnitudes and forms, their inclinations to the ecliptic, and their positions on their planes, are in a state of constant oscillation; fluctuating, however, between certain mean values from which they never greatly depart. See Gravitation, Perturbation.

Hypothesis of Laplace, respecting the Formation of the Planetary System.—The motion of the planets in elliptic orbits, and the relation between their periods and distances, are necessary consequences of the law of gravitation which prevails throughout the universe; but the solar system presents several remarkable phenomena of which gravitation fails to give any account, which cannot be supposed to be the effect of accident, and which lead almost irresistibly to the conclusion that all the bodies which belong to it have had a common origin, and been formed under the agency of the same mechanical laws. All the planets, as well as satellites, move in the same direction, from west to east. The orbits of all the large planets are situated very nearly in the plane of the ecliptic; and, so far as has been discovered, they all revolve about their axes in the same direction, also from west to east. To account for these phenomena, Laplace

has hazarded the speculation that all the planets and satellites have had their origin in the solar atmosphere, which he supposes to have extended beyond the orbits of the most distant planets, and to have undergone a progressive contraction by the radiation of heat into the stellar spaces. Now, as the solar atmosphere partakes of the sun's rotation about his axis, and in fact may be regarded as part of his mass, in proportion as its limits are contracted by cooling the rotatory motion must increase, according to a well-known principle of mechanics; and the centrifugal force thus becoming greater, the point or limit at which it is balanced by gravity approaches nearer the centre. Supposing, therefore, the atmosphere to have extended to this limit at any epoch, it must, in cooling, have abandoned the molecules situated there and at the different limits successively produced by the increased velocity of the sun's rotation. This effect, however, would only take place at the equator; for on the parallels of latitude the centrifugal would not equal the attractive force. Thus, zones of vapours would continue to be abandoned at the equator; and if the condensation of the molecules of these zones continued without any disunion taking place, the matter would, in the long run, form a solid or liquid ring, circulating about the sun in the plane of his equator. But the uniformity which would be necessary for the production of this effect, both in all the parts of the zone and in the cooling, must render such a phenomenon extremely rare. In fact, the ring of Saturn is the only instance of it in the planetary system. In almost every case each zone of vapours must have been broken up into numerous masses, which, moving with nearly the same velocities, would continue to circulate about the sun, nearly at the same distances. These separate masses would assume the spheroidal form, with a motion of rotation in the same direction as their revolving motion; in short, they would become so many planets in the state of vapour. But if any one of them was considerably larger than the rest, it would finally by its attraction unite all the others about its centre; and thus the zone originally abandoned would be transformed into a single spheroidal mass of vapours, circulating about the sun. This latter case must have been the most common. An instance, however, of permanent separation occurs in the four small planets between Mars and Jupiter.

Conceiving the planet to have been detached from the solar atmosphere in the manner now described, the further cooling would occasion a nucleus to be formed at its centre, which would progressively increase by the condensation of the vapours surrounding it. The condition of the planet would now perfectly resemble that of the sun, and consequently similar results would follow from the continuance of the condensation. Hence the formation of the satellites from the atmospheres of the planets, as the planets are formed from that of the sun.

This hypothesis of Laplace does not explain the origin of the comets, which may be regarded as small nebulosities wandering from one solar system to another, and formed by the condensation of nebulous matter, which appears to be scattered through the universe in great profusion. Whatever may be the fate of the hypothesis, it must be allowed the merit of assigning a mechanical cause for some of the most remarkable phenomena of the universe, without invoking the aid of any other force than that of gravity, — a property which belongs to matter in every form. *See* Astronomy, Satellite, Star, Sun.

PLANE TABLE. An instrument employed in land-surveying, by means of which a plan is made on the spot, without any protraction or measurement of angles. It consists of a plane rectangular board, about sixteen inches square, to the under side of which a centre is attached with a ball and socket, or parallel plate screws, by which it can be fixed upon a staff head or three-legged stand, and set horizontal by means of a circular spirit level. A boxwood frame is accurately fitted round the edges of the board, for the purpose of stretching and retaining the drawing paper. It is usual to divide one face of the frame into 360° from a centre in the middle of the board; but this graduation is scarcely of any use, and may be dispensed with. The reverse face of the frame is divided into equal parts, as inches and tenths, for the convenience of ruling parallel lines and squares, and for shifting the paper. A compass-box with a magnetic needle is screwed into one side of the table, to indicate the bearings, and to enable the surveyor to set up the instrument at a new station parallel to the position it had at a former one. A brass rule or index, with a sloping edge, and having perpendicular sight-vanes erected at each extremity, completes the apparatus.

The plane-table is used as follows: — Two stations are selected as the extremities of a base line, the distance between which is accurately measured, and a line drawn on the paper, representing that distance according to the assumed scale. The instrument is then set up at one of the stations, and a fine needle or pin being stuck into the table, at one extremity of the line drawn on the paper, the edge of the index is brought to press gently on the pin and coincide with the line, and the table turned round till the object at the second station is bisected through the sight-vanes; the table is then clamped, and the direction of the magnetic meridian marked. The fiducial edge of the index, still in contact with the upright pin, which serves as a centre, is then directed successively to all the different objects which have been selected as stations, and lines drawn on the paper in the direction of each. This being done, the table is removed to the second station, and the pin placed at the corresponding point on the paper, which forms a second centre. The edge of the ruler is then directed, as before, to each of the objects which were observed from the first station, and lines drawn in those different directions. The intersections of the lines drawn from the second centre with those drawn from the first marks on the paper the position of each of the observed objects.

The plane table is not susceptible of great accuracy, but it is extremely useful in forming a sketch-map, or filling up the details of a survey, where the principal points have been fixed by the theodolite, or some equivalent instrument. *See* Surveying.

PLANETA'RIUM. A machine for exhibiting the relative motions of the planets, and their positions in respect of the sun. *See* Orrery.

PLA'NIPENNATES, *Planipennes.* (Lat. planus, *flat;* penna, *a feather.*) The name of a tribe of Neuropterous insects, comprehending those which have flat wings, of which the inferior pair almost equal the superior ones, and are simply folded underneath at their anterior margin. The antennæ are multiarticulate, much longer than the head, without being subulate or styliform. The maxillary palps are usually filiform or somewhat thicker at the extremity, shorter than the head, and composed of from four to five joints. The ant-lions (*Myrmeleon*) and termites are examples of this tribe.

PLA'NISPHERE. A projection of the sphere and its various circles on a plane. *See* Projection.

PLANK. (Fr. planche.) In Architecture, a board that exceeds nine inches in width.

PLANO-CONCAVE. In Optics, a lens which is plane on one side and concave on the other. *Plano-convex* is a lens plane on one side and convex on the other. *See* Lens.

PLANO'RBIS. (Lat. planus, and orbis, *an orb.*) A genus of marsh snails, so called from the form of the shell, which is that of a flattened orb, arising from the volutions being coiled on the same plane. Many species of this genus are common in Britain.

PLANT. In Natural History. *See* Botany.

PLANTA'GENET. The surname of the royal family of England from Henry II. to Richard III. inclusive. The origin of the name is involved in deep obscurity. The best antiquaries derive it from the well-known story of the Earl of Anjou, the ancestor of the royal race, who having made a pilgrimage to Rome, where he was scourged with broom twigs, assumed the name of *Plantagenista* (literally, a *broom twig*), which his descendants retained. The name Plantagenet belongs to the noble house of Buckingham.

PLANTA'TION. A piece of ground planted with trees, for the purpose of producing timber or coppice wood. In new countries not generally cultivated, and more especially in warm climates, the term plantation is applied to land employed in the culture of the more important crops; such as the sugar-cane, coffee, pepper, cotton, &c. In Britain it is exclusively applied to lands planted with trees or shrubs.

PLA'NTIGRADES, *Plantigrada.* (Lat. planta, *the sole of the foot;* gradior, *I march.*) The name of a tribe of Carnivorous Mammals, comprehending those which apply the whole or a great part of the sole to the ground in progressive motion.

PLA'NTING. The art of forming plantations of trees. Also the art of inserting plants in the soil by the spade, dibble, trowel, or by other means in use in agriculture and gardening. *See* Arboriculture.

PLA'SHING. A mode of repairing or modifying a hedge by bending down a portion of the shoots, cutting them half through near the ground, to render them more pliable, and twisting them among the upright stems, so as to render the whole effective as a fence, and at the same time preserve all the branches alive. For this purpose the branches to be plashed, or bent down, must not be cut more than half through, in order that a sufficient portion of sap may rise up from the root to keep alive the upper part of the branches. Where hedges are properly formed and kept, they can very seldom require to be plashed; but this mode of treating a hedge is most valuable in the case of hedges abounding with hedgerow trees, when from neglect, or from any other cause, the hedge has become of irregular growth.

PLA'STER. In Architecture, the material of which ornaments are cast, and also that with which the fine stuff or gauge for mouldings and other parts is mixed, when quick setting is required.

Plaster. In Pharmacy, a compound, generally of oxide of lead and olive oil, for external applications.

PLASTER OF PARIS. *Gypsum*, or sulphate of

lime, commonly termed *plaster stone*, and found abundantly near Paris.

PLA'STIC. (Gr. πλασσω, *1 form.*) In Sculpture, that which can be modelled, as clay, &c. In the arts it has a more extended signification, and signifies those materials and circumstances which are susceptible of being formed and fashioned to the purpose wanted.

PLASTIC CLAY. A clay used in the manufacture of pottery. See also GEOLOGY.

PLA'TANIST, *Platanista.* A name applied by Pliny to a fish in the river Ganges, having a snout and a tail like a dolphin, but much larger. In modern Zoology, it is the generic appellation of the Gangetic dolphin (*Delphinus gangeticus*, Cuv.).

PLA'TBAND. (Fr. plate and bande.) In Architecture, a square moulding projecting less than its height or breadth. The fillets between the flutes of columns are sometimes called, but improperly, by this name. It is also sometimes used to denote the lintel of a door.

PLATE. (Fr. platte.) In Architecture, a piece of timber lying horizontally on a wall for the reception of the ends of girders, joints, rafters, &c.

PLATE. The name usually given to gold and silver wrought into articles of household furniture. For the regulations under which the manufacture of plate is carried on, see the *Com. Dict.*

PLA'TFORM. (Fr. plateforme.) In Architecture, a plane surface, lying level, of any materials used in a foundation or elsewhere, for the reception of the foundations of a building, or for the piers of a bridge: also a level scaffold, raised above the ground for a temporary purpose.

PLATFORM. In Artillery, an elevated floor on which guns are placed.

PLATING. The art of covering copper and other metals with silver or gold: it is effected in various ways. Sometimes the silver is attached to and rolled out with the copper by pressure; sometimes the one metal is precipitated from its solutions upon the other; and of late manufacturers have availed themselves of electro-chemical decomposition for the purpose. *See* VOLTATYPE.

PLA'TINUM. (So called from the Spanish word plata, *silver*, on account of its colour.) A metal of a white colour, exceedingly ductile, malleable, and difficult of fusion. It is the heaviest substance known, its specific gravity being 21·5. It undergoes no change from air or moisture, and is not attacked by any of the pure acids; it is dissolved by chlorine and nitromuriatic acid, and is oxidized at high temperatures by pure potassa and lithia. It is only found in South America and in the Uralian Mountains: it is usually in small grains of a metallic lustre, associated or combined with palladium, rhodium, iridium, and osmium; and with copper, iron, lead, titanium, chromium, gold and silver; it is also usually mixed with alluvial sand. The particles are seldom so large as a small pea, but sometimes lumps have been found of the size of a hazel nut to that of a pigeon's egg. In 1826, it was first discovered in a *vein* associated with gold by Boussingault, in the province of Antioquia, in South America. When a perfectly clean surface of platinum is presented to a mixture of hydrogen and oxygen gas, it has the extraordinary property of causing them to combine so as to form water, and often with such rapidity as to render the metal red hot: *spongy platinum*, as it is usually called, obtained by heating the ammonio-muriate of platinum, is most effective in producing this extraordinary result; and a jet of hydrogen directed upon it may be inflamed by the metal thus ignited, a property which has been applied to the construction of convenient instruments for procuring a light. The equivalent of platinum is about 98. It is precipitated from its nitromuriatic solution by sal ammoniac, which throws it down in the form of a yellow powder, composed of bichloride of platinum and sal ammoniac.

PLATO'NIC BODIES. The five regular geometrical solids, so called because they were treated of or described by Plato. They are the tetraedron, the hexaedron, the octaedron, the dodecaedron, and the icosaedron. Besides these five, there can be no other solids bounded by like, equal, and regular plane figures, and whose solid angles are all equal.

PLA'TONISM. The philosophy of Plato. To give a satisfactory account of the system of this great thinker, within the limits which the nature of the present work necessarily impose upon us, would be an undertaking of no common difficulty. Those of our readers who are adequately conversant with the original writings of Plato must be well aware that the views entertained in our own country of his philosophical character and merits are, to say the least, partial and incomplete; while those who add to this knowledge an acquaintance with the researches of our German contemporaries on this subject will admit the possibility, at the same time that they appreciate the difficulty, of attaining a fuller and more adequate comprehension. The leading characteristic of the mind of Plato is its comprehensiveness. This quality discovers itself equally in the form in which his philosophy is communicated, and in that philosophy itself. The form to which we allude is, it is well known, that of the dialogue. The Dialogues of Plato are at once vivid representations of Athenian life and character, and constituent parts of a system of universal philosophy; the harmonious productions of a genius which combined the dramatic imagination with the scientific intellect in a degree which has never before nor since been equalled. It is in this circumstance that we must seek alike for the influence which Plato's writings have exerted, and for the difficulty of rightly apprehending their meaning. What has been said of history in general may with equal truth be applied to the Platonic dialogues — that they are "philosophy teaching by examples." In place of a formal refutation of sophistry, we are introduced to living sophists; in the room of an elaborate system of philosophy, we meet the greatest philosophers of his day, reasoning and conversing with disciples eager in the pursuit of knowledge, — with Athenians full of natural prejudices, with men abounding with individual peculiarities.

Under no other or less complex form of composition could Plato have accomplished the manifold purposes which he had in view; purposes not of the philosopher only, but of the reformer and educator of the moral and intellectual nature of his countrymen. In most of his dialogues one or other of these intentions is the prominent one; in some the refutation of false philosophy, in others the establishment of his own; while others again seem chiefly designed as exemplifications of scientific method generally; though we agree with Schleiermacher in thinking that there are none which do not contribute to the gradual development of his own system.

But it is not merely in the form in which his doctrines are clothed that we discern the comprehensiveness of Plato's genius. The same quality is, as we have said, equally apparent in the philosophy of which his dialogues are the vehicle. By referring to the articles ELEATIC, IONIC, and PYTHAGOREAN PHILOSOPHY, the reader will be able to form some conception of the systems which preceded that of Plato. In each of these some leading idea is taken up, and traced, generally to the exclusion of all others, through all its possible consequences. These three schools may, indeed, be severally taken as the representatives of the three constituent portions of universal philosophy: the Eleatics of the logical or dialectic; the Ionians of the physical; and the Pythagoreans, though in a less exclusive degree, of the ethical element. It was in Plato that these different tendencies first converged. Each viewed by itself was essentially partial and one-sided, and, with whatever of truth it might contain, must necessarily, by its very exclusiveness, combine much of error. Of this circumstance the sophists had taken advantage, and, by setting the doctrines of one system in contradiction to those of another, had succeeded in the introduction of a universal scepticism. Plato was thus led clearly to discern the necessity of laying the foundations of science deeper than they had been laid by his predecessors. The ultimate unity of all knowledge, properly so called, and the mutual dependence of all its parts on each other, is the fundamental intention of his philosophy. How this first principle was to be attained, whether, indeed, it were attainable or not, could only be ascertained by a previous inquiry into the nature, not of *being*, but of *knowledge*. This is one mark which distinguishes Plato from earlier speculators; and it is important to bear it in mind, if we would form a correct estimate of the services rendered by him to the progress of philosophy. The hint was unquestionably given by Socrates, but Plato was the only one among his immediate disciples who appears to have followed it up. He may, in truth, be styled the founder of the ancient psychology; and the dialogue entitled *Theætetus* may be considered one of the most important contributions to the most important branch of that science, the theory of perception and judgment, which antiquity affords. It is in this dialogue that the negative side of the inquiry into knowledge, which we have alluded to, is contained. Knowledge, it is there shown, is not to be confounded either with the impressions on the senses, or with the judgments (δόξας) founded upon them. Sensation, by its very nature, is relative only: it is the joint effect of the conditions of our internal constitution and a motion, or change, communicated from without. Judgment, in so far as it is founded on a prior impression, can have no validity save in reference to that impression. Pure knowledge, therefore, if it exist at all, must be sought in some other direction. It is here that the celebrated doctrine of ideas finds its place. Without entering into the question more deeply than our limits allow, it is sufficiently clear that no other word, such as conception, notion, or the like, is adequate to convey all that Plato meant by an *idea*. Having failed in finding alike knowledge in the senses and permanent being, its object in nature, he was driven, in order to avoid the sophistic doctrine of the relative nature of all knowledge, to seek for the true objects of reason in something distinct from the material universe. In place of the doctrine of Protagoras, "Man is the measure of all things," he substituted, "God is the measure of

all things;" meaning by this, as he elsewhere explains himself, that in the divine nature reason and being are one. From this original unity, which is denominated by Plato the good, or the supreme good, proceed, on the one hand, human reason; on the other, those ideas which constitute all in nature that is real; all, that is, which the reason can apprehend. We might hence be led to suppose that the modern term "law" may be correctly used in place of the Platonic "idea." But, when we examine the matter more narrowly, we shall find an essential difference between the two words, not merely in the ontological or theological considerations just alluded to, but also in the habit, which Plato inherited from his master Socrates, of referring the laws of the universe to a moral or *teleological* standard. The three great ideas of truth, beauty, and order or fitness, are the ultimate unities to which he conceives it to be the business of the reason to refer all its conceptions. These ideas are themselves included in the highest unity, or God, from whom it is that they derive their reality. But the supreme nature is to us incomprehensible; it is in the consciousness of our separation from the great source of being that philosophy takes its rise. The senses it is which first suggest to us this want: we strive to bring their phenomena under general conceptions; and every attempt to understand the sensible is a self-recognition of the reason, and a step towards divinity. Theology is therefore the ultimate science in which all the other sciences converge: dialectics, as the science of the true, ethics as the science of the morally beautiful, and physics as that which discerns the order and fitness of outward things. Such is a very imperfect sketch of the Platonic idea of science in its three constituent parts. The threefold division above given we nowhere find expressly laid down in the written works of Plato; but, besides that it is throughout implied, the fact that it is taken for granted by his immediate successors, Xenocrates and Aristotle, justifies us in supposing that it formed part of Plato's oral communications. But, besides this comprehensive view of universal science, we are indebted to Plato for many valuable discoveries, and many more most pregnant hints, in subordinate branches of inquiry. Among these may be enumerated the discussion of the theory of pleasure and pain, and their relation to desire and emotion, in the *Philebus;* of the first principles of the science of grammar in the *Cratylus* and *Sophist;* of the nature of mathematical science, and its place in general philosophy, *Rep.* vi., &c. The ethics of Plato, though, in many important respects, they must be allowed to be greatly defective, as, in particular, in the omission of the notions of duty and responsibility, are yet far from deserving the contemptuous treatment they have met with from certain writers among ourselves. In the *Republic*, which contains the substance of his moral doctrines, the intention of Plato manifestly was to develop the idea of perfect humanity, alike in the individual, and in what he regarded as an enlarged transcript of the individual, the state. (*See* ETHICS.) The most important contribution to the study and right understanding of the Platonic philosophy, with which modern times have furnished us, is to be found in the arrangement of his *Dialogues*, and the introduction prefixed to each, by the celebrated Schleiermacher, a work which has recently been translated into English. See also *Ritter*, *Gesch. der Philosophie*, b. viii.; and, for some abstruse portions of Plato's doctrine, *Trendelenburg's Ideæ Plat. ex Aristot. illust.*

The best editions of Plato's works are those of Bekker and Hallbaum. For an account of his life, see *Ast's Leben und Schriften Platon.*

PLATOO'N. In the art Military, a small square body of musketeers, drawn out from the main body to strengthen the angle of a larger square, or to do duty in ambuscades or defiles, &c., when there is not room for whole regiments or battalions to act.

PLA'TYRHINES, *Platyrhinæ.* (Gr. πλατυς, *wide*, and ῥιν, *a nose*.) The name of a section of the Linnæan genus *Simia*, including those species which have the nostrils separated by a wide interspace. These monkeys are peculiar to the New World.

PLA'TYSOMES, *Platysoma.* (Gr. πλατυς, and σωμα, *body*.) The name of a family of Coleopterous insects comprehending species with a wide and much depressed body. These insects are found under the bark of trees, and form the genus *Cucujus* of Fabricius, now subdivided.

PLEA'DING. (Lat. placitum, Norman French plaid, together with the verb placitare, *to plead;* derived from placitum, the decree or sentence of a judicial or legislative authority.) Pleadings, in English law, are the preparatory allegations in writing which intervene between the commencement of a cause and its trial.

The first object in deciding a dispute between two litigant parties is always to ascertain the subject for decision. This must be accomplished by disengaging the point in debate from all the extraneous matter in which the complaints and answers of the respective parties have involved it. This is the principle from which all the subtleties of the system of pleading, commonly called *special pleading*, are derived; and, in so far as it has departed from this object, it has wandered from its original purpose.

Pleadings were conducted orally in the first times of our jurisprudence; the parties, or their advocates, exposing the state of facts on which they relied successively before the judge, who moderated between them, and answering each other until the judge was able to fix upon the point at issue, as it was called; that is, the question, whether of fact or law, on which the judge, or the jury, was eventually to decide. Hence issues are said to be *in fact* or *in law*. The same principle governs the course of *written pleadings* now adopted.

The plaintiff, or complaining party, having summoned the defendant into court, by a writ stating the nature of his complaint, makes his first statement, which is termed a *declaration*. The defendant may now answer him, either by denying that there is any ground in law for the action, either because there is defect *in substance* in the plaintiff's alleged right, or defect *in form* in his proceedings; or by controverting the facts which he alleges, or alleging new facts in answer to them. In the former case the defendant *demurs* to the declaration; in the latter case he answers by one or more *pleas*.

A demurrer may take place either at this or at any subsequent stage of the proceedings; and may be made either by plaintiff or defendant. And it is either *general* to substance, or *special* to form. (But, by the increased liberality of the courts, many errors in form may now be amended on application which formerly were fatal.) If the demurrer comes to be argued (which is done in term time, or in bench, before all the judges of the court in which the action is brought), the court will examine the whole pleadings on both sides; and their decision on the point of law is final as to the action.

The defendant may answer or *traverse* the facts, 1. By pleading what is termed *the general issue;* a form which, in its original signification, implied an absolute denial of the facts on which the plaintiff founded his complaint; and concludes with the words, "and of this the said defendant puts himself on the country," that is, offers to have the issue tried by a jury. But, by the refinements introduced into pleading, the general issue was gradually admitted, in each of the several *forms of action* to which we shall presently refer, not only to deny the plaintiff's facts, but to allow the defendant to bring forward other facts in answer; although these more properly form the subject, 2. of *special pleas*. When the defendant admits all or a part of the plaintiff's facts, but relies on certain other facts as exonerating him from the liability asserted by the plaintiff, he ought to state these facts in answer; for instance, in order to answer the claim of a debt, that it is barred by length of time, or that the defendant has a set-off to allege against it: this is termed a plea by way of confession and avoidance. The plea stating such new facts concludes with the assertion, "and this the said defendant is ready to verify." To this the plaintiff may reply in his second statement, called a *replication*, either by denying the defendant's facts, that is, a replication *by way of traverse*, or by alleging fresh ones; the defendant may deny these, or again allege fresh ones, in his *rejoinder;* sometimes a *surrejoinder*, a *rebutter*, and a *surrebutter* may be added; and the edifice of pleading is raised by stories gradually narrowing, by the exclusion of superfluous facts, until it reaches its summit in the production of one or more issues, either in law or fact, the decision of which finally arranges the dispute; and, by what are called the new rules of pleading, framed in 1834, many defences which might formerly have been given under the general issue must be pleaded specially.

Thus, in an action of debt, the defendant pleads *specially* the statute of limitations, that is, that more than six years have passed since the cause of action accrued; the plaintiff replies, admitting the length of time, but alleging that the defendant has since promised to pay the debt; this the defendant denies in his rejoinder; and hereupon, *i.e.* on the fact of the promise, issue is joined.

A plaintiff complains of breach of covenant by his lessee, in not repairing premises. The defendant pleads, admitting the lease and the want of repair; but alleges that he had received from the plaintiff a release from all his liability. The plaintiff replies, admitting the release, but asserting that it was obtained from him by force or duress. The defendant may perhaps deny the legal sufficiency of this ground, or *demur to the replication;* or he may traverse it in his rejoinder, denying the force or duress. In the former case, an issue of law is raised for the court; in the latter, an issue of fact for the jury.

The attorneys for the parties deliver in their respective pleadings on paper to the officers of the court. When issue is joined, these pleadings are entered on a parchment roll, and the issue is likewise entered; in the form of appointing a day for the trial of the demurrer, if the issue be in law; or in the form of a precept to the sheriff of the county named in the pleadings, to summon twelve good and lawful men for the trial of the issue in fact. This roll is called the record, and is preserved as an au-

thentic memorial of the proceedings in the case; the verdict, and the judgment, being entered on it.

Such is a brief outline of the forms of pleading as applicable to every injury of which complaint can be made in the courts of common law. But, according to the nature of the injury complained of, his action will assume a particular form, allotted by law to enable him to recover the particular remedy he seeks. *See* ACTION, and the FORMS OF ACTION, under their several heads.

PLEASURE-GROUND. That portion of ground adjoining a dwelling in the country which is exclusively devoted to ornamental and recreative purposes. In the ancient style of gardening, the pleasure-ground was laid out in straight walks, and regular or symmetrical forms, commonly borrowed from architecture; but, in the modern style, it is laid out in winding walks, and in forms borrowed direct from nature. A portion of lawn or smooth grassy surface may be considered as essential to the pleasure-ground under both styles.

PLEBE'IANS. The free citizens of Rome who did not come under the class of the patricians or clients. Though always personally independent, they had in early times no political power, the government being entirely in the hands of the patricians, who, with their clients and the king, formed the original people. The class of plebeians was of after growth, and probably drew its numbers from various sources, as from clients whose obligations were dissolved by the decay of the houses of their patrons, and the inhabitants of conquered states who were admitted to rights of citizenship. The plebeian families with patrician names are supposed to have arisen from marriages of disparagement contracted between the higher and lower classes.

As this body, from its constitution, naturally grew in vigour while the patricians became weaker, it soon formed the main strength of the Roman armies, and became desirous of sharing in the advantages of the conquests made by its prowess; while the patricians, on their part, tenaciously clung to all their privileges, and, far from yielding to the demands of the other party, exercised the severe rights which as creditors they possessed over the liberties of many of its members. This state of things produced a continued series of collisions between the two orders, in which the latter gradually gained ground, till, in the last ages of the republic, it was admitted to a full share of all the powers and privileges before confined to one order.

PLEBISCI'TUM. (Lat. *a decree of the people.*) In Roman History, a law enacted by the common people, under the superintendence of the tribune or some subordinate plebeian magistrate, without the intervention of the senate. The term, however, is used in a more peculiar sense, being applied chiefly to the law made when, upon a misunderstanding with the senate, they retired to Mount Aventine.

PLE'CTOGNATHES, *Plectognathi.* (Gr. πλέκω, *I connect*, and γναθος, *a jaw.*) The name of an order of fishes, including those which have the maxillary bones anchylosed to the sides of the intermaxillaries, which alone form the jaws.

PLE'CTROPO'MA. (Gr. πλῆκτρον, *a spur*, and πωμα, *a lid.*) A name applied by Cuvier to a genus of Percoid fishes, characterized by having the angle of the preoperculum produced, or divided into a series of spines, like those which arm the rowel of a spur. All the species are exotic, and belong to warm climates.

PLE'CTRUM. (Gr. πληκτρον; from πλησσω, *I strike.*) The small ivory instrument with which the ancients struck the lyre.

PLEI'ADES. In Mythology, the seven daughters of Atlas and Pleione were so called, whose names were Alcyone, Maia, Electra, Merope, Calano, Sterope, and Taygeta. They were loved for seven years by Orion, from whose solicitations they were at length released by the interposition of Jupiter, who transformed them to the stars, where they now form a cluster in the neck of the constellation Taurus. Only six of these stars are visible to the naked eye; and the ancients supposed that the seventh concealed herself, out of shame for having bestowed her love on a mere mortal, Sisyphus, while her sisters were the favourites of divine personages.

PLE'NARTY. (Lat. plenus, *full.*) In Law, the state of a benefice, office, &c., when full: in opposition to vacancy.

PLENE ADMINISTRA'VIT. (Lat.) In Law, a plea pleaded by an executor or administrator to an action on a liability of the deceased, that he has *fully administered* his goods.

PLE'NICORNS, *Plenicornia.* (Lat. plenus, *full*, and cornu, *a horn.*) The name of a tribe of Ruminants, including those which have horns composed of an uniform solid osseous substance as the antlers of deer. *See* CORNUA.

PLENIPOTENTIARY. *See* AMBASSADOR.

PLE'ONASM. (Gr. πλεον, *more.*) In Rhetoric, a redundant phrase or expression, sometimes introduced to give additional energy, at other times needless and ungraceful.

PLE'SIOMO'RPHISM. (Gr. πλησιος, *near*, and μορφη, *form.*) A term applied to crystallized substances the forms of which closely resemble each other, but are not absolutely identical. The primary form of sulphate of strontia is a rhombic prism very similar to that of sulphate of baryta; but, on measuring the inclination of corresponding sides on each prism, the difference exceeds 2°. Similar differences are observable in the rhomboedrons of carbonate of lime and carbonate of iron. Such substances, therefore, are *plesiomorphous.*

PLE'SIOSAUR, *Plesiosaurus.* (Gr. πλησιος, and σαυρος, *a lizard.*) The name of a genus of extinct marine saurians, chiefly remarkable for their length of neck. The head is small, but like that of a crocodile; the vertebræ are articulated generally by nearly plane surfaces; the cervical vertebræ have an articular surface, divided by a longitudinal impression, for a rudimental rib on each side, and two vascular foramina beneath the digital bones of both the hind and fore extremities are flattened, and are enveloped in a sheath of skin like the paddles of the *Cetacea.* The remains of the *Plesiosauri* occur in the formations from the muschel-chalk to the chalk inclusive; but are most common in the lias and kimmeridge clay beds.

PLE'THORA. (Gr. πληθω, *I fill.*) A redundant fulness of the blood-vessels. It results from various causes, generally referred to *sanguine plethora*, to which the robust and athletic are most subject; and to *serous plethora*, which attacks debilitated constitutions.

PLEU'RA. (Lat.) The membrane which covers the inner surface of the thorax and its viscera. It forms two distinct portions, or bags, which, being applied laterally to each other, form the partition called the *mediastinum.*

PLEURI'TIS, *Pleurisy.* Inflammation of the pleura. This disease begins with fever, cough, pain in the side, a peculiar hard and strong pulse: the symptoms often run on with great rapidity, attended by very painful respiration and other alarming symptoms. (*See* PNEUMONIA.) The treatment must be prompt and decided: it consists in bleeding, blisters, and purging; and in the after treatment, great care must be taken against an insidious and local form of the disease, which often extends to the lungs.

PLEU'RONECTIDÆ. (Gr. πλευρα, *a side*, and νεκτης, *a swimmer.*) The name of a family of Jugular fishes which swim on their side, and of which the genus *Pleuronectes*, or sole, is the type; they are commonly called flat-fishes.

PLI'CA. (Lat. plico, *I entangle.*) A disease said to be peculiar to Poland, Lithuania, and Tartary, in which the hair becomes matted and inextricably entangled. It is often called *Plica Polonica.*

PLI'CIPENNATES, *Plicipennes.* (Lat. plico, *I fold*, and penna, *a feather.*) The name of a tribe of Neuropterous insects, comprehending those which have the inferior wings wider than the others, and folded longitudinally. The mandibles are wanting in this tribe, which is represented by the genus *Phryganea*, or caddis-flies.

PLINTH. (Gr. πλινθος, *a brick.*) In Architecture, the lowest member of the base of a column, bearing, as its name indicates, the form of a square brick or tile. (*See* BASE.) Sometimes the abacus of the Tuscan capital is called the plinth of the capital.

PLI'OCENE. (Gr. πλειων, *greater*, and καινος, *recent.*) A geological term applied to the most modern of the divisions of the tertiary epoch, because the major part of its fossil testacea are referable to recent species. *See* GEOLOGY.

PLO'TTING, in Surveying, signifies describing or laying down on paper the several angles and lines of a tract of land which has been surveyed and measured. It is usually performed by means of a *protractor* (see the term); sometimes by the *plotting scale.*

PLO'TTING SCALE. A mathematical instrument used in *plotting*, or setting off the lengths of lines in surveying. It consists of two graduated ivory scales, one of which is perforated nearly its whole length by a dovetail shaped groove, for the reception of a sliding piece to which the second scale is attached, and with which it moves, the edge of the second being always at right angles to the edge of the first. By this means the rectangular co-ordinates of a point are measured at once on the scales; or the position of the point laid down on the plan.

PLO'TUS. A genus of web-footed birds of the family *Pelicanidæ*, and nearly allied to the cormorants. They are generally known by the name of *Anhinga*, or "darters," from the rapidity with which they shoot down into the water in the capture of fish. The white-billed anhinga (*Plotus melanogaster*) is the most common and best known species: it is a native of the tropical regions of both North and South America.

PLOUGH. (Germ. pflug.) An implement drawn by horses and guided by a driver, by which the surface of the soil is cut into longitudinal slices, and successively raised up and turned over. The object of the operation is to expose a new surface to the action of the air, and to render it fit for receiving the seed, or for harrowing, or for

other operations of agriculture. Ploughs are of two kinds: those without wheels, commonly called swing-ploughs; and those with one or more wheels, called wheel ploughs. The essential parts which compose both kinds of plough are, the beam by which it is drawn; the stilts or handles by which the ploughman guides it, being two levers connected with the beam; the coulter fixed into the beam, by which the furrow-slice is cut; the share, also attached to the beam, by which the slice is raised up; and, finally, the mould-board, by which the slice is turned over. The most improved form of the swing plough is that in general use in Scotland and the North of England, which is known as a modification of what is called Small's improved swing plough. The most improved wheel plough is the same implement, with a wheel attached to the beam, for the purpose of keeping the share at a uniform distance beneath the surface. The subsoil plough, the invention of Mr. Smith, of Deanston, in Stirlingshire, is the swing plough, of a somewhat stronger construction than that in common use, but without the coulter and the mould-board. The use of this implement is to follow the common plough, and lessen the subsoil at the bottom of the furrow without raising it to the surface. The most improved form of this implement contains a muzzle (the instrument by which it is drawn), so contrived as that the horses may walk on the firm soil. The use of the subsoil plough is one of the greatest modern improvements that has been introduced into the culture of arable land. Draining ploughs are of different kinds. The mole plough, instead of a share and mould-board, has a small iron cylinder attached to the lower extremity of the coulter, and which, being drawn through grass land, leaves in its track a small opening, which has been compared to the underground track of a mole, and into which the water percolates from the surface through the narrow slit formed by the upper part of the coulter, and is thus carried off to an open drain. The other kinds of draining ploughs cut out the soil, raise it to the surface, and turn it over in the manner of the common plough, thus leaving a deep furrow, which is commonly further deepened and modified by the spade, and afterwards partially filled with stones, draining tiles, or other materials through which water may find its way, and finally covered with the surface soil. Draining ploughs, though in theory promising a saving of manual labour, yet in practice are found inconvenient, from the number of horses required to work them. Their use is, therefore, generally confined to free, deep, loamy soils, with an even surface.

PLOUGHING. The act of turning over the soil by means of the plough. Trench ploughing is effected by the plough passing twice along the same furrow; the first time for the purpose of throwing the surface soil into the bottom of the furrow; and the second time for raising a furrow slice from under that which had been already turned over, and raising it up, &c., turning it upon the first furrow slice, by means of which the surface soil is entirely buried, and a stratum of subsoil laid over it: thus effecting in the field what trenching with the spade does in the garden. Trench ploughing can only be employed with advantage where the subsoil is naturally dry and of good quality, or where it has been rendered so by draining and subsoil ploughing; for bad subsoil brought to the surface would be unfit for receiving seeds or plants. *See* PLOUGH.

PLUG. In Architecture, a piece of wood driven horizontally into a wall, its end being then sawn away flush with the wall, to afford a hold for the nailing up dressings, &c.

PLUMBA'GIN. A crystallizable substance, extracted from the root of the *Plumbago Europæa*.

PLUMBA'GO, *Graphite, Black Lead*. This useful substance is a compound of carbon, generally with a minute quantity of iron; there is, however, some doubt as to the nature of the combination. The finest plumbago is from Borrodale in Cumberland.

PLUMB-LINE, PLUMMET. (Lat. plumbum, *lead.*) A heavy body (usually a piece of lead, whence the name) suspended by a flexible thread for the purpose of indicating the perpendicular to the horizon, or the direction of terrestrial gravity. In former times, the plumb-line constituted an essential part of the apparatus employed for adjusting astronomical instruments; but it is seldom used in modern observations, excepting those made with the zenith sector, its place being either more conveniently supplied by the spirit level, or the method of determining the zenith point by combining direct and reflected observations rendering it unnecessary. For the common artificer's plummet, see LEVEL.

PLU'MULA. (Lat. pluma, *a feather.*) The growing point of the embryo, situated at the apex of the radicle and at the base of the cotyledons, by which it is protected when young. It is the rudiment of the future stem of a plant.

PLUPE'RFECT TENSE. (Lat. plus quam perfectum, *more than perfect.*) In Grammar, the tense which denotes that an action was finished at a certain period to which the speaker refers.

PLURAL. *See* GRAMMAR.

PLURA'LITY. In Ecclesiastical Law, the holding of more than one benefice. It was ordained in the council of Lateran, A.D. 1215, that whosoever should take any benefice with cure of souls, if he should before have attained a like benefice should, *ipso facto*, be deprived of the latter. Exceptions were made to this rule in certain cases of *in commendam*, by a constitution published in the council of Lyons; but it could always be evaded by dispensation from the pope. Since the Reformation, dispensations in England are granted by archbishops. The first English enactment on the subject was that of 21 H. 8. c 13., and rendered the former benefice void if of the value of 8*l*. or above. A benefice, therefore, with which another may be held, must be below that value in "the king's books." By the 4th Canon, 41., no licence or dispensation for the holding of more benefices than one can be granted to any one, unless a graduate as A.M. in one of the universities; and he must reside a reasonable time on each benefice, and licensed as a preacher; nor may they be more than thirty miles asunder; and he must have under him a preacher properly licensed in that where he resides least. Formerly, dispensations even from the injunctions of this canon were obtained from the crown; but none, it is said, since the Revolution. The practice was very common in this country in Roman Catholic times; and though, as we have already observed, restrained by various statutes, still subsist to a considerable extent. Until every benefice is made capable of supporting an incumbent, it is manifestly impossible to abolish it entirely; and, in the case of an individual holding one rich and one poor living together, the arrangement may frequently be practically advantageous. Under the existing laws (1836), dispensations for holding two benefices may be obtained on various pleas; but measures of further restraint are understood to be in contemplation.

PLUS. In Algebra, the additive or positive sign +, which, being placed between two quantities, signifies that they are to be taken collectively, or added together. According to Dr. Hutton, this character was first used by Stifelius, as a contraction of the letter *p*, the initial of *plus*.

PLUTO. (Gr. Πλούτων.) Called also Hades (Αΐδης), Aïdoneus (Αϊδωνεύς) by the Greeks, or Orcus by the Romans, was the brother of Jupiter and Neptune, and lord of the infernal regions. He is not, like his brothers, celebrated for amours, but remained faithful to Proserpine, whom he carried away from the plains of Sicily, and made his queen.

Pluto is represented as an old man with a dignified but severe countenance, holding in his hand a two-pronged fork.

PLUTO'NIC ROCKS. Unstratified crystalline rocks, probably formed at great depths beneath the surface by igneous fusion. The term is opposed to *volcanic rocks*, also formed by fire, but having cooled near the surface. *See* GEOLOGY.

PLUTUS. (Gr. πλοῦτος, *wealth.*) The god of riches, said to have been the son of Jasius and Demeter or Ceres. There are no particulars known as to his worship; but he is introduced as an actor in the play of Aristophanes which bears his name, and he bears a part also in the *Timon* of Lucian.

PLUVIAMETER. (Lat. pluvius, *rain.*) *See* RAIN-GAUGE.

PNEUMA'TICS. (Gr. πνευμα, *air or breath.*) The science which treats of the mechanical properties of elastic fluids, and particularly of atmospheric air.

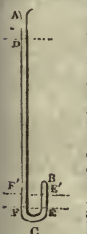
Elastic fluids are divided into two classes,— permanent gases, and vapours. The gases cannot be converted into the liquid state by any known process of art; whereas the vapours are readily reduced to the liquid form by pressure, or diminution of temperature. In respect of their mechanical properties there is, however, no essential difference between the two classes.

Elastic fluids, in a state of equilibrium, are subject to the action of two forces; namely, gravity, and a molecular force acting from particle to particle. Gravity acts on the gases, in the same manner as on all other material substances; but the action of the molecular forces is altogether different from that which takes place among the elementary particles of solids and liquids; for, in the case of solid bodies, the molecules strongly attract each other (whence results their cohesion), and, in the case of liquids, exert a feeble or evanescent attraction, so as to be indifferent to internal motion; but, in the case of the gases, the molecular forces are repulsive, and the molecules, yielding to the action of these forces, tend incessantly to recede from each other, and, in fact, do recede, until their further separation is prevented by an exterior obstacle. Thus, air confined within a close vessel exerts a constant pressure against the interior surface, which is not sensible, only because it is balanced by the equal pressure of the atmosphere on the exterior surface. This pressure exerted by the air against the sides of a vessel within which it is confined is called its *elasticity*, or *elastic force*, or *tension*.

Conditions of equilibrium. — In order that all the parts of an elastic fluid may be in equilibrium, one condition only is necessary; namely, that the elastic force be the same at every point situated in the same horizontal plane. This condition is likewise necessary to the equilibrium of liquids, and the same circumstances give rise to it in both cases; namely, the mobility of the particles, and the action of gravity upon them. Conceive a close vessel to be filled with air, or a gas; and let a and b be two molecules situated in the same horizontal plane. It is evident that if the two molecules are in a state of equilibrium, the force with which a repels b must be exactly counteracted by that with which b repels a, for otherwise motion would take place. The same thing takes place in respect of every horizontal section of the gas; but the pressure on each section varies with its altitude. Suppose c and d to be two molecules situated in a horizontal section, *lower* than that in which are a and b. It is evident that the molecules c and d sustain a greater pressure than a and b; for, in the first place, the whole of the pressure on a and b is transmitted to them by the principle of the equality of pressure in all directions; and, in the second place, they sustain a new pressure, arising from the weight or gravity of all the molecules situated between the two horizontal planes $a\,b$ and $c\,d$.

The principle which has just been explained is proved experimentally by the diminution of the pressure of the atmosphere at greater altitudes. A column of air reaching from the ground to the top of the atmosphere exerts a pressure equal to the weight of a column of mercury of the same diameter, and whose height is equal to that in the barometric tube. Now, on carrying the barometer to the top of a mountain, for example, the mercurial column is observed gradually to become shorter as we ascend; and the diminution of the column, and consequently of atmospheric pressure, is connected with the increase of altitude by a certain constant law, which enables us to deduce the one from the other, and to apply the barometer to the very important purpose of determining the relative altitudes of places on the surface of the earth. *See* HEIGHTS, MEASUREMENT OF.

Law of Mariotte. — In order to determine the relation between the density and pressure of the elastic fluids in the state of equilibrium, let A C B be a graduated bent tube (like a siphon barometer), having two unequal branches, of which the shorter is hermetically sealed at B, and the longer open at A. Let a small quantity of mercury be poured into the tube, just enough to fill the bend, and intercept the communication between the air in C B and the external atmosphere, and let the level E F be marked at which it stands in the two branches of the tube. It is evident that in this state the pressure of the air imprisoned between E and B is exactly equal to that of the atmosphere. Now, let mercury be poured into the tube at A; it will rise slowly in the branch E B, and much more rapidly in the open branch F A. Let mercury then be continued to be poured in until it stands at two points, D and E′, so situated that the altitude of D above E′, or D F′, is just equal to the height of the column in the barometer, or about 30 inches. In this state, the elasticity of the air in the space E′ B is in equilibrium with the pressure arising from the weight of the mercurial column F′ D, and the pressure of the atmosphere exerted on D. But the weight of the mercurial column F′ D is just equal to the atmospheric pressure, consequently the air in E′ B is compressed by a force equal to twice the atmospheric pressure. Now, on observing the length of the column E′ B, it will be found exactly one half of E B, or the air has been reduced to half its former volume. On increasing the length of the open branch of the siphon, and pouring in a proper quantity of mercury, it is found that a pressure of three atmospheres reduces the volume of air at B to one third, and of four atmospheres to a fourth of its first volume; whence it is inferred, generally, that *the volumes of gases are inversely as the pressures which they support.* This fundamental property of elastic fluids is called the *Law of Mariotte*, from its having been discovered by that philosopher in France. It has been verified in several ways, on all the known gases; and, in the case of dry air, its verification has been pushed, by MM. Dulong and Arago, to pressures equivalent to twenty-seven atmospheres. (Lamé, *Cours de Physique.*) It also holds true in respect of vapours or steam subjected to a smaller degree of pressure than that which is necessary to reduce them to the liquid state; and even for mixtures of different gases. It is important, however, to observe, that it is supposed no variation of temperature has taken place during the experiment. The apparatus above described is called a *manometer*.



The density of bodies being inversely as their volumes, the law of Mariotte may be otherwise expressed, by saying *the density of an elastic fluid is directly proportional to the pressure it sustains.* Under the pressure of a single atmosphere, the density of air is about the 770th part of that of water; whence it follows that, under the pressure of 770 atmospheres, air is as dense as water. Thus, the average atmospheric pressure being equal to that of a column of water of about 32 feet in altitude, at the bottom of the sea, at a depth of 24640 ($= 770 \times 32$) feet, or $4\frac{2}{3}$ miles, air would be heavier than water; and though it should still remain in a gaseous state, it would be incapable of rising to the surface.

Effects of Heat on the Elasticity of the Gases. — The repulsive energy of the molecules of the elastic fluids is greatly augmented by an increase of temperature; and it is of the utmost importance in many physical inquiries to ascertain the relation between the temperature and the elastic force. If air and several other gases, sustaining the same constant pressure, are exposed to an increase of temperature which affects all of them equally, it is proved by observation that they all undergo an equal expansion; that is to say, the increase of volume of all the gases is the same for equal augmentations of temperature, and proportional to these augmentations. Experience also shows that, within a considerable range of temperature, the indications of the air thermometer differ very little from those of the mercurial thermometer; so that, within this range, the expansion of any gas whatever is proportional to the increase of temperature indicated by the degrees of the ordinary thermometer. From the temperature of melting ice to that of boiling water, or from zero to 100° of the centigrade thermometer, Gay-Lussac found the expansion of air subjected to a constant pressure to be in the ratio of unity to 1·375; which gives an expansion of 0·00375 for each centigrade degree. This being assumed, let V be the volume of any gas at the zero temperature, P its elastic force, or the pressure it sustains, and D its density. Let $a = \cdot 00375$, and suppose the values of V and D to become V′ and D′ when the temperature is increased t degrees; then the pressure P being supposed constant, we have evidently

$$V' = V\,(1 + at);$$

and the density being inversely as the volume, we have also

$$D' = \frac{D}{1 + at}.$$

Now suppose the pressure to be varied without any change of the temperature, and let p denote the new pressure, and d the corresponding density; the law of Mariotte gives

$$P : D' :: p : d, \text{ whence } p = \frac{P\,d}{D'};$$

and on substituting for D′ its value given by the preceding formula, and making $\frac{P}{D} = k$, we obtain

$$p = kd\,(1 + at)$$

for the expression of the elastic force of any gas in a function of its density and temperature.

The coefficient k is constant for the same gas, but has a different value for different gases, depending on their densities or specific gravities. With respect to atmospheric air, its value may be found thus:—The density of air, compared with water, is 0·0013, and that of mercury 13·59; therefore, supposing the height of the barometer to be 30 inches, the value of k, or the height of a column of air of uniform density, exerting on its base a pressure equal to that of the atmosphere, is 30 in. $\times \frac{13 \cdot 59}{\cdot 0013} = 313860$ inches, or 26155 feet (about five miles), the temperature being that of freezing water.

Of the Motion of the Gases. — Elastic fluids, in escaping from a vessel by a small orifice or tube into a vacuum, observe, like liquids, a law first discovered by Torricelli; namely, that the velocity of the molecules, when they escape from the orifice, is equal to that which they would have acquired by falling through a height equal to the height of a vertical column of uniform density, producing the same pressure as is exerted by the gas at the level of the orifice. Thus, it has just been shown that the pressure of the atmosphere when the barometer stands at 30 inches, and the temperature is that of freezing, is equal to that which would be produced by a column of air of uniform density extending to an altitude of 26155 feet. Now, putting $g =$ the accelerating force of gravity $= 32$ feet per second, the velocity which a heavy body would acquire by falling in a vacuum from a height of 26155 feet is $\sqrt{(2\,g \times 26155)} = 8\sqrt{26155} = 1294$ feet in a second; which, therefore, is the velocity with which air rushes into a vacuum. If the temperature varies, the velocity will vary also, and will become $1294\sqrt{(1 + a\,t)}$. For example, if the temperature were 16° centigrade (about 61° of Fahrenheit), the velocity would be 1332 feet per second.

Since the densities of the gases are proportional to the pressures they support, air will always rush into a vacuum with the same velocity, whatever its density may

be in the vessel from which it escapes; for the homogeneous column of the same density, and exercising the same pressure as the air in the vessel, must in all cases have the same altitude.

The velocities with which the different gases enter a vacuum are inversely as the square roots of their densities; for they are proportional to the square roots of the altitudes from which the molecules are supposed to fall, and these altitudes are inversely as the densities. Thus, hydrogen gas, the lightest of all the gases, and whose density is only 0·0688 of that of air, would enter a vacuum with a velocity of 4933 (= 1294 divided by the square root of 0·0688) feet in a second. It is to be remarked, however, that all those laws relative to the flow of gases are rather inferences from theory than truths demonstrated by direct experiment.

In the case of air or any gas flowing into a space containing a gas of an inferior density, the velocity will be the same as that of an incompressible liquid of similar density with the effluent gas, and capable of exercising a pressure equal to the difference between the pressures of the two gases. Taking, for example, the case of a gas flowing from a gasometer into the atmosphere: let h denote the height of the barometer, and $h + \mathrm{H}$ that of the column of mercury exercising a pressure equal to the elasticity of the effluent gas, so that H is the difference of the two pressures. Also let Δ denote the density of mercury, d that of the gas in the gasometer corresponding to the pressure $h + \mathrm{H}$, and v the velocity per second; then

$$v = \sqrt{\left(2g\,\mathrm{H}\,\frac{\Delta}{d}\right)} = 8\sqrt{\left(\mathrm{H}\,\frac{\Delta}{d}\right)}.$$

Now if, in the formula $p = k\,d\,(1 + a\,t)$ we substitute the pressure in the gasometer $(h + \mathrm{H})\,\Delta$ for p, and also for k its value as above determined in feet, this expression will become

$$v = 1294\sqrt{\left\{\frac{\mathrm{H}}{h + \mathrm{H}}\,(1 + a\,t)\right\}},$$

where v is expressed in feet. If, therefore, A denote the area of the orifice in feet, the volume or number of cubic feet discharged in a second will be v A. It is to be observed, that the volume thus determined is the volume of a gas of the same density as in the gasometer; if it were required to find the number of cubic feet at a different density corresponding to the pressure of a mercurial column whose height $= h'$, it would be necessary to multiply the above expression by the ratio $(h + \mathrm{H}) \div h'$.

From the experiments of D'Aubuisson, it has been ascertained that air, in passing through an orifice pierced in a thin plate, forms a *vena contracta*, whose area, as in the case of a liquid, is 0·65 of the area of the orifice. The application of cylindric adjutages increases the quantity issuing through the orifice to 0·93, and a conical tube to 0·95. The length of the adjutage may be 20 or 30 times the diameter of the orifice before the discharge begins to be diminished by friction. If, therefore, we suppose the gas to flow through a cylindric tube, and assume the multiplier 0·93; and also express the area of the orifice in terms of the diameter of the tube, which we shall suppose $= m$ feet; then, observing that $4\,\mathrm{A} = 3{\cdot}14159\,m^2$, the formula for the number of cubic feet discharged in a second, the density being measured by $h + \mathrm{H}$, will become

$$945\,m^2\sqrt{\left\{\frac{\mathrm{H}}{h + \mathrm{H}}\,(1 + a\,t)\right\}}.$$

The principle of the lateral communication of motion holds good with respect to the gases as well as the liquids. On this principle we may explain a curious fact, observed in the efflux of air from a blowing machine, and in the escape of steam from the valves of boilers. If a circular disk of four or five times the diameter of the orifice be placed close to it, not only will it not be forced away by the current of the elastic fluid, but it will be retained by a considerable force; insomuch that if the orifice be directed downwards, the disk, though formed of a dense metallic substance, will be supported in opposition to its gravity. Let air issuing with considerable force through the aperture A B have its course interrupted by the metallic plate C D; the current will assume the form of a conoid E A B F, containing the cavity E G F. At first the space C G D will be filled with the effluent air; but if a lateral communication of motion takes place, the air in this conoid will join itself to that which escapes by the edges of the plate, and a vacuum be formed in the space C G D, and the plate C D be forced towards the aperture by the pressure of the atmosphere on the opposite side. But as it approaches the orifice the action of the effluent air will become more intense, and the dimensions of the void space be diminished, so that the plate will assume a position in which the forces tending to move it in opposite directions will be balanced.

It has been demonstrated by Newton, in the second book of the *Principia*, that the velocity with which sound is propagated through the air is the same as that which a heavy body would acquire by falling through *half* the height of the homogeneous atmosphere, and consequently equal to $8\sqrt{13078}$, or about 915 feet per second. But this theoretical determination is found to differ considerably from experiment, which gives a velocity of 1125 feet per second when the temperature of the air is at 62° of Fahrenheit's thermometer. Laplace suggested a very probable explanation of this discrepancy; namely, that the condensation caused by the vibrations produced a degree of sensible heat by which the elasticity of the air is increased, or, rather, the density diminished, while the elastic force remains the same. In consequence of this extrication of heat, the number given by the formula of Newton must be multiplied by the square root of the number which expresses the ratio of the specific heat of the air under a constant pressure to its specific heat under a constant volume. This number is found by experiment to be 1·375, the square root of which is 1·173; and on applying this correction, with the proper corrections for temperature, the theoretical determination does not differ very widely from the experimental result. *See* Sound.

Pneumatics forms a branch of physical science which has been entirely created by modern discoveries. Galileo first demonstrated that air possesses weight. His pupil Torricelli invented the barometer; and Pascal, by observing the difference of the altitudes of the mercurial column at the top and the foot of the *Puy de Dome*, proved that the suspension of the mercury is caused by the pressure of the atmosphere. Otto Guericke, a citizen of Magdeburg, invented the air-pump about the year 1654; and Boyle and Mariotte, soon afterwards, detected by its means the principal mechanical properties of atmospheric air. Analogous properties have been proved to belong to all the other aeriform fluids. The problem of determining the velocity of their vibrations was solved by Newton and Euler, but more completely by Lagrange. The theoretical principles relative to the pressure and motion of elastic fluids, from which the practical formulæ are deduced, were established by Daniel Bernoulli, in his *Hydrodynamica* (1738); but have been rendered more general by Navier (*Mem. de l'Acad.* 1830). The experiments of D'Aubuisson, above referred to, are given in different volumes of the *Annales de Chimie* (1826, 1828, 1829). *See* Gas, Resistance, Vapour.

PNEUMATIC RAILWAY. *See* Railroad.

PNEUMATO'MACHI. (Gr. πνευμα, *spirit*, and μαχη, *contest.*) In Ecclesiastical History, a name of reproach, given by the orthodox to those various classes of heretics who, in the fourth and fifth centuries, impugned the divinity of the Holy Ghost. *See* Macedonians.

PNEUMATO'SIS. (Gr. πνευματοω, *I inflate.*) Emphysema. A collection of air in the cellular membrane, rendering the part tumid, elastic, and crepitating when pressed. It rarely arises spontaneously, but generally from some wound which affects the lungs, and by which the air spreads through the cellular membrane. In some rare cases it is an effect of certain poisons.

PNEUMOBRAN'CHIATES, *Pneumobranchiata.* (Gr. πνευμα, *air*, βραγχια, *gills.*) A name applied by Hunter to the Perennibranchiate reptiles of recent zoologists; and by Lamarck to an order of Gastropodous mollusks.

PNEUMO'NIA, or PNEUMONITIS. An inflammation of the lungs. This disease generally attacks those of robust habit after exposure to the cold or wet, and suppressed perspiration; it is sometimes produced by any inordinate exertion of the lungs. Fever, cough, difficult breathing, a strong, hard, and quick pulse, usher in the disease, which, if neglected, sometimes proceeds so rapidly as to end in suffocation; it may also prove fatal by terminating in suppuration and gangrene. A free and abundant expectoration, perspiration, or diarrhœa, are favourable symptoms of its termination in resolution. Large bleeding at the outset, repeated, however, with much circumspection, local bleeding, purges, and diaphoretics of calomel and antimony, and afterwards small doses of opium, hemlock, and such remedies as quiet the cough and procure sleep, constitute the leading principles of treatment.

PNEU'MOTHO'RAX. (Gr. πνευμα, and θωραξ, *chest.*) An accumulation of air in the sac of the pleura.

POA. (Gr. ποη, *grass.*) A name given by botanists to a genus of grasses of considerable extent, and very abundant in the pasturages of Europe. One of the commonest of all weeds is the *Poa annua*. *Poa trivialis* and *pratensis* are other species, sown extensively as a part of the artificial pastures and lawns, which are now commonly made with picked grasses instead of "hay seeds." In general, they appear to be nutritious and agreeable to cattle.

POACHERS. *See* Game Laws.

POCO. (Ital.) In Music, a word frequently prefixed to another to lessen the strength of its signification; as *poco largo*, a little slow.

PO'DAGRA. (Gr. πους, *the foot*, and αγρα, *a seizure.*) *See* Gout.

PODESTA. One of the chief magistrates of Genoa and Venice is so called.

PODE'TIA. (Gr. πους, *a foot.*) The stalk-like elongations of the thallus, which, in certain lichens, support the fructification, as in *Cenomyce.*

PO'DICEPS. (Gr. *divided foot.*) A genus of birds, commonly called *Grebes*, placed in the order of Palmipeds by Cuvier, but forming the transition from the waders to the swimmers by having the webs of the toes incomplete, and formed by a scalloped membrane, as in the coot. The legs are, however, placed far back, so as to render them efficient organs of swimming, while their use in walking on dry land is proportionally deteriorated; the feet are admirably organized for propelling the body through the water; and the grebe, which dives more than it swims, assists the feet with a simultaneous action of its wings; but these, like the pectoral fins of fishes, serve mainly to direct and vary the course of the bird.

PO'DIUM. (Lat.) In Architecture, the part in an amphitheatre projecting over the arena, above which it was raised about 12 or 15 feet: in this part sat the personages of distinction. The word is also used to signify a balcony.

PŒ'CILE. (Gr.) A celebrated portico or gallery at Athens, where Zeno inculcated his doctrines. The Pœcile was adorned with the statues of gods and benefactors; and the picture of Polygnotus, so well known to the classical reader, which represented Miltiades at the head of the 1000 Greeks at the battle of Marathon, was here suspended for ages.

PŒ'CILOPODS, *Pœcilopoda.* (Gr. ποικιλος, *varied*, and πους, *a foot.*) The name of an order of Entomostracous Crustaceans, including those which have feet of different forms and uses, the anterior ones being ambulatory or prehensile, the posterior branchial and natatory.

POETRY. (Gr. ποιησις, *a poem*, and ποιητικη τεχνη, *the art of poetry;* from ποιεω, *I make*, according to Aristotle, because the writers of each different class of poems, epic, elegiac, &c., were said, in common language, to "make" them; and called εποποιοι, ελεγειοποιοι, *epic-makers*, and *elegy-makers. De Poet.* sec. iii.) To produce a complete and satisfactory definition of poetry has been, hitherto, unsuccessfully attempted by writers on taste, and by poets themselves. A popular one, sufficiently adapted to general notions, is furnished by the *doyen* of living critics, Lord Jeffrey: — "The end of poetry is to please; and the name, we think, is strictly applicable to every metrical composition from which we derive pleasure without any laborious exercise of the understanding." (*Ed. Rev.* xi. p. 216.) But, in the first place, it has been truly observed, that "verse is the limit by which poetry is bounded: it is the adjunct of poetry, but not its living principle."—"Poetry," says Coleridge, "is not the proper antithesis to prose, but to science. Poetry is opposed to science, and prose to metre."—"The proper and immediate object of science is the acquirement or communication of truth; the proper and immediate object of poetry is the communication of immediate pleasure." In the next place, Lord Jeffrey's definition would clearly include burlesque composition. Is this strictly *poetry?* It was included, certainly, in their rather artificial analysis of poetry by ancient critics: in the *Poetics* of Aristotle the rules of comic composition are as elaborately laid down as those of any other species. Yet the excitement of the ridiculous is altogether of a different nature from that produced by poetry in the modern sense of the word: which is necessarily either elevating, imaginative, or tender. And this it does, as Coleridge, with a true poetical feeling, has described it, by communicating to the reader "that pleasurable emotion, that peculiar state and degree of excitement, which arises in the poet himself in the act of composition." (*Literary Remains.*) The end of poetry, then, appears to be to produce intellectual pleasure by exciting emotions either of the elevated or pathetic order. But in what mode does poetry effect this? The sight of a distressed object raises tender feelings; a tale of distress does the same: to be witness of some stupendous event, or great natural phenomenon, elevates them; and so does the description of such. Yet this tale or description is not poetry. Some dramas, almost utterly destitute of poetical merit, retain a hold on theatrical audiences merely because they are transcripts of painful scenes actually occurring in domestic life. But these are not poetry, although constantly mistaken for it. So again, the mere narration of a grand and surprising circumstance is not poetry, however akin to poetical the emotion it inspires. Few passages in poetry retain a greater hold on the imagination than the well-known accounts of Napoleon amidst the fires of Moscow, or the sack of Rome by Bourbon, or the execution of Charles the First, or mere descriptions of the Alps or Niagara: the most prosaic writer who treats these subjects, if he only adhere to truth and bring out its striking particulars, cannot fail of producing an effect which may be termed, as regards the reader, poetical; but not by the employment of poetry. This consideration leads us to its great characteristic. It is essentially a creative art: its operation is "making," not transcribing. "Imitation" it is, as Aristotle defines it; not because it copies, but because it has its model in nature, and can never depart far from it without losing its character. Lord Bacon explains this by saying, that poetry "doth raise and erect the mind, by *submitting the shows of things to the desire of the mind.*" The imagination alters these "shows of things" by adding or subtracting qualities; and poetry produces to view the forms which result from the operation.

But Lord Jeffrey goes on, in the passage which has been already quoted, to give an analysis of the elements of poetical pleasure, which appears to us singularly clear and accurate. "This pleasure may, in general, be analysed into three parts: that which we receive from the excitement of passion or emotion; that which is derived from the play of imagination, or the easy exercise of reason; and that which depends on the character and qualities of the diction." The two first are the vital and primary species of poetical delight. And this analysis may lead us to consider the faculties by the exercise of which these several pleasures are produced, — faculties widely different, yet all poetical; some of them more and some less essential to the production of poetical pleasure; some less and some more conspicuous in different poets; all united in hardly any.

1. Imagination is, emphatically, the great poetical faculty. It is "the first moving or creative principle of the mind, which fashions out of materials previously existing new materials and original truths." It is "a complex power, including those faculties which are called by metaphysicians conception, abstraction, and judgment:" the first enabling us to form a notion of objects of perception and knowledge; the second "separating the selected materials from the qualities and circumstances which are connected with them in nature;" the third selecting the materials. (*Stewart:* see the article "Poetry" in the *Encycl. Britannica.*) Its operations are most various, and it exhibits itself in poetry in very different degrees and forms. It may shine here and there, chiefly in comparison, or in bold and pleasing metaphor, breaking the chain of a narrative, as in Homer and the earlier poetry of most nations; it may hurry image on image, connected only by those exquisite links of thought which are present in the mind of the poet, in daring, compressed, rapid language, as if language were inadequate to its expression, as in the inspired prophets, in Æschylus, and often in Shakspeare; it may predominate in entire sustained conceptions, grasping at general features, as in Milton; it may cling more closely to the "shows of things," dwelling in particulars, reproducing with startling vividness images little altered, graphic, and minute, as in Dante; and here it often approaches to fancy. Imagination, combined in a greater or less degree with thought or reflection, but with little of the other poetical qualities, produces a kind of poetry which suits the taste of a refined and thoughtful class, but has little hold on the general mind; departing too widely from Milton's rule in being, if simple, neither "sensuous nor passionate," of which striking examples may be found in Wordsworth, and sometimes in Goethe, a writer of a very different cast.

2. No distinction has given critics more trouble, in the way of definition, than that between imagination and fancy. "Fancy," it has been said, "is given to beguile and quicken the temporal part of our nature; imagination to incite and support the eternal." — "The distinction between fancy and imagination," says another, "is simply that the former altogether changes and remodels the original idea, impregnating it with something extraneous; the latter leaves it undisturbed, but associates it with things to which in some view or other it bears a resemblance." Now the latter is an operation of thought, wit, or judgment; and this perhaps will lead us to a right conclusion. The poetry of true fancy is merely that of imagination "at a lower point of excitement," or employed on less elevated subject matter. The poetry of the *Midsummer Night's Dream*, for instance, may be termed either imaginative or fanciful with equal correctness. But there is also a spurious fancy, the offspring of a quick wit, adopting poetical diction: are we wrong in calling this the real quality of one of the most charming of modern poets, whose wit is very nearly allied to imagination, yet not the same, — Thomas Moore?

3. Lord Jeffrey, as we have seen, associates with the pleasure of imagination that derived from "the easy exercise of reason." This is produced chiefly by the faculties of thought, wit, and reflection. It may indeed be doubted whether the expression of thought, however energetic and acute, clad in current poetical diction, is really poetry. Certainly it is so, if at all, in a very inferior degree to that of the imagination. And yet when we reflect how much of the pleasure which we derive from verse is of this kind, how many of the greatest names in the history of poetry are distinguished for this alone, and that one great literary nation (the French) seems to have placed its idea of poetry entirely in the expression of thought and feeling, and chiefly the former, we can scarcely refuse it an important place. It also takes many

shapes. It appears in the form of witty or acute conceits, as in Donne and Cowley, and many French and Italian poets; nearly allied to that spurious fancy of which we have spoken. It lightens in flashes of high-minded indignation or keen sarcasm in Juvenal; assumes a still loftier moral tone in Persius, and often in Dryden, mixed with grave, energetic, powerful reflection. It takes the easier tone of acute knowledge of the ways of man, and light satire, in the pages of Horace, and enlivens the charming narrative of Ariosto. It often assumes a rhetorical character, as in Corneille and Lucan. There is a trivial experiment by which the difference between this and imaginative poetry may be tested. Turn both into prose; the latter retains its poetical character; the former seems to lose it.

4. The expression of passion, sentiment, or pathos, is the most common and universal of all sources of poetical pleasure. It is the very soul of all early and simple poetry; it pervades no less that of the most civilized communities. Yet this class of poetry is less truly and emphatically poetical than the imaginative; although more popular. The pleasure occasioned by it is of a mixed nature: it arises from the excitement of peculiar sympathies, not produced, but heightened only, by the form in which that excitement is conveyed. This is the reason why mere popularity is not a test of the excellence of poetry. The uncritical reader calls that the best poetry by which he is best pleased. Devotional poetry, for instance, appeals to an elevated and universal class of sympathies; and on this account often passes for worth more than, as poetry, it really is. The highest attribute of a poet, in this branch of the poetical faculty, is a sensibility to all the springs of our passions, joined with the art of expressing it; these, when united with that power of personification which is more peculiarly the dramatic faculty, produce the drama in its highest and noblest shape, such as it is exhibited by Shakspeare, and by him alone. But the power of giving language to the sentiments of any common and elevated passion is by itself a great poetical merit. The passion of love is the staple of numberless bards. The passion for war or conflict, unhappily natural to man; is a source of poetry: it is impossible not to perceive in Homer and Scott, independently of their art of narration and energy of description, an exultation in the animal excitement of the imaginary battle, the *certaminis gaudia* of the savage Attila, peculiarly and intensely poetical. The sentiment of self-love, the natural propensity to exhibit self to self in a romantic or elevated point of view, forms a great part of the charm of such a muse as that of Byron. Again, independently of the direct expression of feeling, there is in some poets a general colouring derived from it, thrown as a light veil over all the objects presented, which is a singularly attractive attribute. Such is the tinge of grave and serious tenderness which shades the poetry of Sophocles and Virgil; and assumes, perhaps, a more feminine character in that of Tasso.

These are the more strictly subjective qualities of true poetry. There are others, of a more objective character, which can scarcely be said to belong to it strictly *as* poetry, and yet can scarcely be excluded from a general review.

5. The dramatic faculty, of which we have already spoken, seems to consist in acute powers of observation of the varieties of human character, together with the rarer power of delineating it with such force as to bring the imaginary person distinctly before the reader. It is the wonderful and unique characteristic of Shakspeare, in whom all individuality, as has been often observed, seems absolutely lost. If we are to look for a second to Shakspeare in this high faculty, we shall find him, among poets, only in Scott. But it is a power often much developed in writers who are not poets in any sense, such as Le Sage and De Foe.

6. The descriptive faculty is of the same kind; that of bringing the objects of external nature, or passing scenes of whatever sort, vividly before the reader's fancy. When the objects or scenes so represented are such as the painter might choose with advantage for the exercise of his art, the faculty is properly termed picturesque; though that word is often of a looser acceptation. It is obvious that this also is a faculty common to poets, with many others who are not so; but sustained energy of description, as in Homer, forms a magnificent ground work for strictly poetical ornament. In the poetry of modern times, especially in this country, and in Germany, the description of external nature has been made subservient to the purposes of imagination and reflection by writers of high genius; and this combination peculiarly characterizes the taste of the age.

7. Lord Jeffrey ranks last the pleasure derived from diction, as of a secondary order; which it undoubtedly is, and yet almost essential. The highest poetry, without beauty of style, is rarely or never popular. We have no space to characterize minutely this poetical quality; but, by way of example, it may suffice to observe, that Virgil is, perhaps, of all poets, he of whose charm the greatest proportion is derived from simple beauty and felicity of diction; through a whole range of ill-chosen subjects, always graceful, always equable, and as nearly approaching to faultlessness as human skill can construct.

8. Lastly, we must not omit the pleasure of *melody:* not essential to poetry, since there may be poetry without verse; not always a merit of the poet's own, since much depends on the language, — and a Greek or Italian poet, cæteris paribus, will ever be preferable to an English or German one, on this account alone; but a grace which heightens the charm of the noblest poetry, and sometimes captivates the sense even in the most indifferent.

POIKILI'TIC FORMATION. (Gr. ποικιλος, *variegated.*) In Geology, a term applied to the new red sandstone formation, in consequence of the varieties of colours which it exhibits.

POI'NDING. In Scottish Law a species of diligence (*i. e.* process), whereby the property of the debtor's moveables is transferred to the creditor. Poindings are either real or personal; the former affecting the debtor's moveables on the lands to which the debt attaches, the other his moveables generally. The effect of real poinding is to give the user of it right to the rents.

POINT. A steel instrument used by engravers for tracing the work on a copper-plate.

POINT. In Heraldry, an ordinary somewhat resembling the pile (*see* PILE), but issuing from the base of the escutcheon instead of the chief: seldom used in English, but frequently in foreign armories.

POINT. In Music, a character used by many instead of the dash, its chief use being to distinguish those notes from which an intermediate effect is required dissimilar to the dash.

POINT BLANK, in Gunnery, denotes the position of the gun when pointed so that its axis is parallel to the horizon. *Point-blank range* is the distance to which a shot fired in the *point-blank* or horizontal direction is carried.

POI'NTING, in Artillery, denotes placing the gun so as to give the shot a particular direction. This is usually done by help of the gunner's quadrant or level. *See* LEVEL.

POINTS. Small flat pieces of cordage put through the sails in horizontal rows, for the purpose of reefing them.

POINTS OF SUPPORT, in Architecture, are the collected areas *on the plan* of the piers, walls, columns, &c., upon which an edifice rests, or by which it is supported. It is evident that the smaller their total area, compared with the superficies of the whole building, the greater is the skill exhibited by the architect; and this for many reasons, not the least whereof is the greater resultant economy. We subjoin a table of some few buildings in Europe, examined in this respect. They are arranged in the order of the ratio of their points of support, whose area, as well as their total superficies, are added in separate columns.

Ratio of Area to Points of Support.	Edifice.	Total Area in English Feet.	Area of Points of Support.
0·056	Temple of Claudius in Rome, now church of St. Stefano	36,726	2,051
0·100	Church of St. Sabino in Rome (destroyed) - -	15,139	1,543
0·118	Church of St. Paul in Rome, without the walls of the city	106,513	12,655
0·127	Temple of Peace in Rome -	67,123	8,571
0·129	Church of St. Filippo Neri, Naples - - -	22,826	2,944
0·139	Church of St. Giuseppe, Palermo - - -	26,046	3,611
0·140	Church of Notre Dame, Paris	67,343	8,784
0·146	Church of St. Dominico, Palermo - - -	34,144	4,988
0·151	Church of St. Sulpice, Paris	60,760	9,127
0·154	Pantheon, or Church of St. Geneviéve, Paris - -	60,287	9,269
0·155	Church of St. Peter, ad Vincula, Rome - -	21,520	3,353
0·157	Church of St. Vital, Ravenna	7,276	1,142
0·163	Temple of Juno Lucina, Sicily - - -	6,821	1,110
0·167	Central building of baths of Diocleslan, Rome - -	351,636	58,797
0·169	Cathedral, Milan - -	125,853	21,365
0·170	St. Paul's, London - -	84,025	14,311
0·172	Great Temple at Pæstum -		2,649
0 176	Central building of baths of Caracalla, Rome - -	15,353 275,503	48,911
0·194	Temple of Concord, Girgenti, Sicily - - -	6,849	1,330
0·201	Cathedral Sta. M. del Fiore, Florence - - -	84,802	17,030
0·217	Mosque of Sta. Sophia, Constantinople - -	103,200	22,567
0·232	Pantheon at Rome - -	34,238	7,954
0·235	Ancient Temple Galuzzo, Rome - - -	9,206	2,167
0·261	St. Peter's, Rome - -	227,069	59,308
0·268	Hotel des Invalides, Paris -	29,003	7,790

POINTS OF THE COMPASS. In Geography and Navigation, the points of division of the circle representing the horizon, or of the compass card over which the

magnetic needle is suspended. A diameter of the circle being drawn to represent the meridian, or north and south directions, and another at right angles to it to represent the directions east and west, the circle is thus divided into four quarters, each of which is subdivided into eight equal parts, so that the whole circle is divided into thirty-two equal parts; and the points of division are termed the points of the compass. Each has a particular name, indicating its place with reference to the four principal or *cardinal points;* namely, the north, south, east, and west points. *See* COMPASS.

POINTS OF THE ESCUTCHEON, in Heraldry, are nine. These are marked by letters in the cut attached to the article HERALDRY, which is copied from those in the ordinary English works on the elements of the science. They are — A, dexter chief; B, middle chief; C, sinister chief (Fr. chef, *head*); D, honour point; E, fess point, which is the centre of the shield (fascia, *belt*, or *sash*, from the belt encircling the middle of a man); F, nombril point (navel); G, dexter base; H, middle base; and I, sinister base. It will be observed, that the greater part of these names are taken from those parts of the human body which the shield was taken figuratively to represent.

POI'SON. (Fr. *poison.*) A substance which disturbs, suspends, or destroys one or more of the vital functions. Poisons are classified by Orfila under the four heads of Irritants, Narcotics, Narcotico-acrids, and Putrefiants or Septics. See TOXICOLOGY.

POISON-FANG. The superior maxillary teeth of certain species of serpents are so called; which, besides the cavity for the pulp, appear to be perforated by a second longitudinal canal, which is open at both ends, and receives at that next the base of the fang the termination of the duct of the poison-gland. The tooth essentially consists of a narrow and thin plate, bent upon itself lengthwise, and with the approximated margins adherent together. In some poison-fangs the line of adhesion is visible along the convex side of the tooth.

There is generally but one poison-fang on each maxillary bone, as in the viper and naia; but sometimes there are a few additional teeth behind the principal fang. The fang ordinarily lies recumbent; but when the serpent designs to strike with this weapon, it is erected by a rotatory movement of the jaw, and the poison-gland is at the same time compressed and emptied of its secretion, which is injected through the hollow fang into the wound.

POISON-GLAND. Those glands which secrete an acrid or venomous liquor, which is conveyed along an instrument capable of inflicting a wound, are so termed. The glands at the sides of the head of poisonous serpents, those at the base of the hollow jaws of the centipede, at the aculeated tail of the scorpion, communicating with the sting of the bee or the spur of the ornithorhynchus, are examples.

POLA'CCA. A peculiar vessel with three masts, navigated chiefly in the Levant and other parts of the Mediterranean.

POLAI'RE. A peculiar rig of a vessel, having pole masts, no tops, and sometimes no crosstrees, whereby the yard and sail are lowered almost close down to the yard next below.

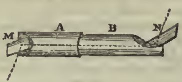
POLAR. Having reference to poles; as *polar circles, polar regions, polar projection*, &c.

POLA'RITY. In Physics, that property of bodies in consequence of which, when at liberty to move freely, they arrange themselves in certain determinate directions, or point, as it were, to given poles. Thus, an iron bar acquires polarity by magnetism, and, when suspended from a single point, arranges itself in the direction of the magnetic meridian, or points to the magnetic poles of the earth. When light is supposed to consist of material particles emitted from the sun, it is necessary, in order to explain certain phenomena of optics, to assume that the particles are endowed with *polarity*, which merely signifies that the opposite sides of a particle have different physical properties. *See* POLARIZATION.

PO'LARIZA'TION OF LIGHT. Light which has undergone certain reflexions or refractions, or been subjected to the action of material bodies in any one of a great number of ways, acquires a certain modification, in consequence of which it no longer presents the same phenomena of reflexion and transmission as light which has not been subjected to such action. This modification is termed the *polarization of light;* its rays being supposed, according to particular theoretical views, to have acquired *poles* (like the magnet), or sides with opposite properties.

The polarization of light may be effected in various ways, but chiefly in the following: — 1. By reflexion at a proper angle from the surfaces of transparent media, as glass, water, &c. 2. By transmission through crystals possessing the property of double refraction. 3. By transmission through a sufficient number of transparent uncrystallized plates placed at proper angles. 4. By transmission through a number of other bodies imperfectly crystallized, as agate, mother of pearl, &c. The following experiment will serve to illustrate the first of these modes, and also give a clear idea of the difference between common and polarized light.

Let A and B be two metallic or pasteboard tubes, open at both ends, and fitting into each so as to turn stiffly. Into each of these let a piece of polished glass, M, N, having one of its sides roughened, and blackened with melted pitch or black varnish so as to destroy its internal reflexion, be fixed in such a position that its surface makes an angle of 33 degrees with the axis of the tubes.



Let the tubes now be placed so that the light from the sun, or any luminary, falling on the plate M, shall be reflected along the axis; and let the tube A be fixed in that position. The light which traverses the axis of the tube will fall on the plate N, from which it will be again reflected, and may be received by the eye, or on a screen. The apparatus being thus arranged, let the tube B be turned round within A, carrying with it the reflector N, which in its revolution will always preserve the same inclination to the axis of the tube; and the ray of light reflected from N will describe a conical surface. Now, on attending to the ray reflected from N, it will be observed in the course of the revolution constantly to vary in intensity: at two opposite points it will acquire a maximum of intensity; and at other two opposite points, intermediate between these, it will entirely disappear. On comparing the positions of the reflecting planes at the occurrence of these phases, it will be found that the intensity of the light is greatest when the plane N is *parallel* to M, and that there is no reflexion from N when the two planes are *at right angles.* It thus appears that a ray of light reflected from the surface of glass at this particular angle of 33° is incapable of being reflected a second time from a similar surface, perpendicular to the former, at an equal angle of incidence. This property is expressed by saying that the light reflected from M is *polarized in the plane of reflexion.* It has, in fact, acquired some property or modification, in virtue of which, while it preserves the power of being again reflected in the same plane, it ceases to be subject to the ordinary law of reflexion in a perpendicular plane.

If the ray reflected from M, instead of being received on a second reflecting surface N, be thrown upon a crystal of Iceland spar, or any doubly refracting crystal, so placed that its principal plane (*i. e.* the plane passing through the direction of the ray and the shorter diagonal of the rhombus) is parallel to the plane of reflexion M, then there will only be a single refraction; the extraordinary ray will disappear, and the ordinary ray alone be produced. But if the face of the crystal be turned round 90°, the phenomena are reversed; the extraordinary ray alone is produced, and the ordinary one disappears. The light, therefore, in consequence of its reflexion from the surface M, ceases to obey the same laws of double refraction as ordinary light.

When the ray reflected from M is received perpendicularly on a tourmaline plate, it will present different phenomena of transmission according to the position of the axis of the plate, that is, the axis of the crystal from which the plate was cut. If the axis is parallel to the reflecting plane, the whole of the light will be transmitted through the plate; but if the plate be turned round in its own plane until the axis becomes perpendicular to the reflecting plane, no portion of the light will be transmitted.

From these experiments it appears that light polarized by reflexion possesses the following characters, which are invariably found to belong to all polarized light, in whatever way the polarization may have been produced: — 1. It is incapable of being reflected by polished transparent bodies at certain angles of incidence, and in certain positions of the plane of incidence. 2. It is incapable of undergoing division into two equal pencils by double refraction, in positions of the doubly refracting bodies in which a ray of ordinary light would be so divided. 3. It is incapable of being transmitted by a plate of tourmaline when incident perpendicularly upon it, in certain positions of the plate; and is readily transmitted by it in certain other positions, at right angles to the former.

The polarization of light by reflexion is only effected completely when the light falls on the reflecting surface at a particular angle; and it has been mentioned that, in the case of glass, the angle which the direction of the ray must make with the surface is about 33°, or the *angle of incidence* (the complement of the former) must be 57°, in round numbers. This angle is called the *polarizing angle*. It is different for different substances; but from an extensive series of experiments with a great number of different bodies, Sir David Brewster found the following remarkably simple and beautiful relation to subsist in all cases between the polarizing angle and the refractive power of the medium, viz. — *The tangent of the polarizing angle for any medium is the index of refraction belonging to that medium.*

All reflecting substances are capable of polarizing light if incident at proper angles; but metallic bodies, and

bodies of very high refractive power, like the diamond, appear to do so only imperfectly, the reflected ray not *entirely* disappearing in circumstances when a perfectly polarized ray would be completely extinguished.

When light is reflected at an angle greater or less than the polarizing angle, it is partially polarized. A second reflexion in the same plane renders the polarization more complete; and, by repeating the reflexions a sufficient number of times, it may be polarized at any angle of incidence.

The second method of effecting the polarization of light, above mentioned, is by transmission through doubly refracting crystals. When a ray of common light is separated into two by double refraction, both the pencils, at their emergence from the crystal, are found to be completely polarized; but in different planes, at right angles to each other. This may be proved by receiving them on a reflecting surface at the polarizing angle, or by examining them through a plate of tourmaline, or by interposing a second crystal also having the power of double refraction; and in all cases each pencil will exhibit the same phenomena as light polarized by reflexion. Let a ray of light fall on a rhomboid of Iceland spar, it will be separated into two, of which call O the ordinary ray and E the extraordinary ray. Let both pencils be received on a second rhomboid, and the following phenomena will be observed. When the rhomboids are in similar positions, or have their homologous faces parallel, neither of the pencils will be separated by the second crystal; but O will produce only an ordinary ray, and E only an extraordinary ray. On turning the second crystal round through an angle of 90°, O produces only an extraordinary ray, and E only an ordinary ray. In intermediate positions, each pencil is separated by the second crystal into two, in the same manner as ordinary light. This experiment, which was first made by Huygens, and accurately described by him, may be made as follows:— Take two pretty thick rhomboids of Iceland spar, and lay them down (the one over the other) on a sheet of white paper, having a small and well-defined black spot on it. When the rhomboids are so placed that their homologous sides are parallel, the spot will be seen double through the combined crystals, as if they formed one piece; both images will be equally bright, and the line which joins them will be parallel to the principal sections of the crystals. This is shown at A in the figure below. If we now turn round the upper crystal in the horizontal plane from left to right, two new faint images will make their appearance, as at B. Continuing to turn, the four images will be all equally luminous, as at C, where the crystal has been turned 45°. As the rotation proceeds, the two original images become extremely faint, as at D. When the crystal has been turned 90°, there will again be only two images, as at E: two new faint images will again appear at F. At G, where the angle of rotation is three quadrants, the four will be again equally bright; farther on at H they will become unequal; and at I, when the revolution is precisely 180°, they will all coalesce into one bright spot.

A B C D E F G H I

From all these appearances it follows that the ordinary ray is polarized in the principal plane of the crystal, and the extraordinary ray in a plane perpendicular to the principal plane.

The phenomena produced by the polarization of light are among the most splendid and singular in the whole range of physical science. They lay open many new views of the constitution of natural bodies, and their explanation constitutes the principal part of the theory of light. The general explanation, according to the Newtonian theory of emission, is this:—The molecular forces of the crystal, acting on the particles of light, give them a rotatory motion round their centres of gravity, till their axes assume certain determinate positions, after which they remain at rest. There are, however, cases in which the luminous particles, in traversing the crystal, assume no fixed position, but oscillate about their centres of gravity in regular periods, termed by Newton *fits;* and there are even cases in which it is necessary to suppose that they are endowed with a continuous rotation. In giving a rational account of these complicated phenomena, and reducing them to calculation, the followers of the undulatory theory have been more successful, and the whole are connected and explained by a simple hypothesis, which may be enunciated as follows:—

"Common light consists of undulations in which the vibrations of each particle are in the plane perpendicular to the wave's motion. The polarization of light is the resolution of each vibration into two, one parallel to a given plane passing through the direction of the wave's motion, and the other perpendicular to that plane, which become in certain cases the origin of waves that travel in different directions. When we are able to separate one of these from the other, we say that the light of each is polarized. When the resolved vibration parallel to the plane is preserved unaltered, and that perpendicular to the plane is diminished in a given ratio (or vice versâ), and not separated from it, we say that the light is partially polarized." (*Airy's Mathematical Tracts*, p. 339.)

The polarization of light by reflexion was accidentally discovered by Malus, a French engineer officer, in the year 1810; and the phenomena, which appeared the most remarkable of any that had yet been observed, both on account of their splendour and their intimate relations with the more interesting parts of physical optics and the theory of light, soon began to be studied with great care, and to be varied in every possible way, by Malus himself, by Biot, Arago, Dr. Young, Seebeck, Sir David Brewster, Sir John Herschel, and many others. But the individual who beyond all doubt contributed most to connect them with theory, and to show their mutual relations and dependencies, was Fresnel, whose success in deriving them, by à priori reasoning, from the principles of the undulatory hypothesis of light, was so complete as to place the evidence of the truth of that theory on almost the same footing of credibility as that of gravitation itself. Analogous phenomena to those of the polarization of light have been found to belong also to radiant heat. Professor Forbes of Edinburgh, who has been the most successful investigator in this interesting department of physics, has shown that heat is polarized both by reflexion and refraction. He has also succeeded in depolarizing heat, and thereby proved that heat possesses the property of double refraction.

See Malus, *Théorie de la Double Refraction;* Fresnel, *Mémoires de l'Institut*, 1824, 1826, 1827; Herschel's Treatise on Light, *Ency. Metr.;* Brewster's "Optics," *Cabinet Cyclopedia;* various papers in the *Phil. Trans.* from 1813 to 1819; *Airy's Math. Tracts*, 2d ed. 1831; and the various scientific journals.

POLE. In Surveying, a measure of length, containing $16\frac{1}{2}$ feet or $5\frac{1}{2}$ yards; it is the same as *rod.* Sometimes the term is used as a superficial measure; a *square pole* denoting $5\frac{1}{2}\times 5\frac{1}{2}$ yards, or $30\frac{1}{4}$ square yards.

POLE'MICS, or POLEMICAL THEOLOGY. (Gr. *πολεμος, war.*) The same as controversial. The term is not necessarily applicable to theology only, but it is generally so applied; and it reflects little credit on human nature that such a subject should have been treated in such a manner as the appellation indicates.

PO'LEMOSCOPE. (Gr. *πολεμος, war*, and *σκοπεω, I view.*) An instrument imagined by Hevelius, for seeing objects which cannot be seen by direct vision. It consists of a mirror placed obliquely in a tube or box, having an opening in the side opposite the mirror, so that rays from any object falling on the mirror are reflected to the eye of the spectator. Hevelius chose the name of *polemoscope* because he thought the instrument might be applied, in time of war, to discover what was going on in the camp of the enemy, while the spectator remained concealed behind a wall or other defence, and therefore could not employ a telescope. Opera glasses are sometimes constructed on this principle, for the purpose of enabling a person to see others on the right or left, while he appears to look straight forward.

POLES. (Gr. *πόλος.*) In Geometry and Astronomy, the extremities of an axis of rotation of a sphere or spheroid. In spherics, the poles of a great circle are the extremities of the straight line perpendicular to the plane of the circle, and passing through its centre. The *poles of the ecliptic* are the points about which the stars are carried by the slow motion of the precession of the equinoxes; the *poles of the equator*, or *poles of the world*, are the two points about which the stars perform their diurnal rotation; the *poles of the horizon* are the zenith and nadir; the *poles of the meridian* are the points of the horizon due east and west.

POLES, in Physics, are the points of a body in which its attractive or repulsive energy appears to be concentrated. Thus, the *poles of a magnet* are the opposite points in which the magnetic force is collected.

POLICE, is a term employed to designate those regulations which have for their object to secure the maintenance of good order, cleanliness, health, &c. in cities and country districts; and it is also used to designate the description of force by which these objects are effected. This force differs from military in its being commanded by civil officers, and not being under military law; but it is generally drilled and armed in a half military manner, and has a distinctive uniform. The police force is employed alike to prevent and detect offences; and may be either open or secret. By an open police is meant officers dressed in their accustomed uniform, and known to every body; while, by a secret police is meant officers whom it may be difficult or impossible to distinguish from certain classes of citizens, whose dress and manners they may think it expedient to assume. The latter are employed that they may, without exciting the suspicion of guilty parties, or of those who are projecting some outrage, acquire their confidence, and, by making themselves masters of their secrets, secure their apprehension or prevent the outrage. It is needless to say that the employment of a

police force of this description is attended with many inconveniences; and sometimes it is believed the officers have stimulated to the commission of the very offences they were employed to detect and prevent. Still, however, it does not seem that it should be altogether dispensed with; and, under proper regulations, it affords not only the best means of detecting crimes, but also of preventing the commission of such as require any previous combination or arrangement.

The organisation and efficiency of the police differ in different places. Its expenses are usually defrayed by a rate laid on the inhabitants of the town or place where it is established. The metropolitan police was newly organised a few years ago, and is now a most effective force. The city of London is not under the charge of the metropolitan police, but is protected by a body of men, organised on the plan and in imitation of that body, but placed under the city authorities. The metropolitan police amounts in all to nearly 4,000 men.

The police or constabulary force of Ireland is armed, and has more of a military than of a civil character. According to recent arrangements, a lord-lieutenant is appointed to each Irish county, through whom all communications to the Irish government are made. The lords-lieutenant are assisted in the discharge of their duties by an indefinite number of deputy lieutenants. All these officers act gratuitously, and are removeable at pleasure.

The constabulary force of Ireland amounted, in 1840, to about 7,650 men, exclusive of a temporary police force of about 650 men.

POLICY. *See* Assurance.

POLISH, *Polishing*. (Lat. polio, *to make smooth*.) In Sculpture, the operation of giving a smoothness and gloss to any surface. The polishing of marble is effected by first rubbing the surface with freestone; after which it is wrought upon with pumicestone; and lastly with the finest emery powder, from which the glossy surface is obtained.

POLITICAL ARITHMETIC. See Statistics.

POLITICAL ECONOMY.* Political science is commonly divided into two great departments. One of these has for its object to ascertain and establish the principles according to which the governments of states may be best organized; to discriminate between the legislative, judicial, and executive departments, and to assign to each its proper functions, limits, and duties; to determine to what hands, and under what conditions and limitations, the supreme power may be most advantageously committed, and how its various subordinate officers should be selected and controlled; to decide, in fine, how the government, under any given set of circumstances, should be framed, so that it may be most likely to promote the well-being of those subjected to its authority. This is what is commonly called pure politics. The other department of political science has a different, more practical, and not less important object in view. Those engaged in its study do not inquire into the best methods of distributing political power, or of constituting the governing body; but, taking them as they exist, they endeavour to ascertain the rules and principles — the *leges legum*, as they were termed by Bacon — according to which all governments, however formed, should act, so as to procure for their subjects the greatest amount of wealth, civilisation, and happiness. This department of the science has received the name of political economy; and we shall endeavour, in this article, to give a brief exposition of its objects and principles. To enlarge on its importance would be superfluous. The history of the human race proves that national prosperity, or the well-being of the bulk of the people, is not the exclusive attribute of any particular species or form of government. It has been and may be enjoyed by all countries, how different soever their political organization, provided they adopt a sound system of political economy; and it can be enjoyed by none who do not. Without, therefore, undervaluing the other great branch of the political sciences, or that which treats of the constitution of governments, this seems to possess at least equal claims on the public attention. Its leading principles and rules are applicable at all times and under all circumstances; they are equally suitable to despotic monarchies and to republics, and cannot be neglected or contemned by either without the most injurious consequences.

It is in general said of political economy that its object is to ascertain the circumstances most favourable for the production of wealth, and the laws which determine its distribution among the different ranks and orders into which society is divided; and this definition seems quite unexceptionable, provided it be clearly understood that by wealth in this science is meant only those articles or products which require some portion of human industry for their production, acquisition, or preservation, and which, consequently, possess exchangeable value. A commodity or product is not valuable merely because it is useful or desirable; but it is valuable when, in addition to these qualities, it can only be procured or enjoyed through the intervention of labour. It cannot justly be said that food or clothes are more useful than atmospheric air; and yet they are possessed of that value in exchange of which the latter is wholly destitute. The reason is, that food and clothes are not, like air, gratuitous products; they cannot be had at all times, in any quantity, and enjoyed without any voluntary exertion. On the contrary, labour is always required for their production or appropriation, or both; and as no one will voluntarily sacrifice the fruits of his industry without receiving an equivalent, they are truly said to possess exchangeable value.

The production and distribution of such articles as exist, and may be obtained in unlimited quantities, independently of voluntary human agency, form no part of the investigations of the political economist. The results of the industry of man comprise the only subjects that come within the scope of his inquiries. This may, indeed, be said to be the science of values, or of the circumstances which determine the production and distribution of products possessed of exchangeable value, or which will be received as an equivalent for something else which it has taken some labour to produce or obtain.

The word *value* is very frequently employed to express, not only the exchangeable worth of a commodity, or its capacity of exchanging for other commodities, but also its *utility*, or capacity of satisfying our wants, or of contributing to our comforts and enjoyments. But it is obvious that the utility of commodities, — that the capacity of bread, for example, to appease hunger, and of water to quench thirst, is a totally different and distinct quality from the capacity of exchanging for other commodities. Dr. Smith perceived this difference, and showed the importance of carefully distinguishing between utility, or, as he expressed it, "value in use," and value in exchange. But he did not always keep this distinction in view, and it has been very often lost sight of by subsequent writers. There can be no doubt, indeed, that the confounding of these opposite qualities has been one of the principal causes of the confusion and obscurity in which many branches of the science, not in themselves difficult, have been involved. When, for example, it is said that water is highly valuable, a very different meaning is attached to the phrase from what is attached to it when it is said that gold is valuable. Water is indispensable to existence, and has therefore a high degree of utility, or of "value in use;" but as it can generally be obtained in large quantities, without much labour or exertion, it has, in most places, but a very low value in exchange. Gold, on the contrary, is of comparatively little utility; but as it exists only in limited quantities, and requires a great deal of labour on its production, it has a comparatively high exchangeable value, and may be exchanged or bartered for a proportionally large quantity of most other things. Those who confound qualities so different must obviously arrive at the most erroneous conclusions. And therefore to obviate all chance of error from mistaking the sense of so important a word as value, it is better not to use it except to signify exchangeable worth, or value in exchange, and to employ the word *utility* to express the power or capacity of an article to satisfy our wants or gratify our desires.

Capacity of appropriation is indispensably necessary to make any thing wealth. A man is not said to be wealthy because he has an indefinite command over atmospheric air, the rays of the sun, or the articles with which, in common with others, he is gratuitously furnished by nature; for this being a privilege which he enjoys in common with every one else, can form no ground of distinction: but he is said to be wealthy according to the degree in which he can afford to command those necessaries, conveniencies, and luxuries that are not the gifts of nature, but the products of human industry.

The proper meaning to be attached to the term wealth being thus ascertained, we shall now proceed to show that labour is the only source of wealth; and having done this, we shall next inquire into the means by which labour may be rendered most efficient, that is, into the means by which the greatest amount of wealth may be obtained with the least expenditure of labour: when this inquiry is completed, we shall have exhausted that great department of the science which treats of the production of wealth.

I. Production of Wealth.

1. *Labour the only Source of Wealth.* — It may be necessary, perhaps, to observe at the outset, that by production, in this science, is not meant the production of matter, that being the exclusive attribute of Omnipotence; but the production of *utility*, and consequently of value, by appropriating and modifying matter already in existence, so as to fit it to satisfy our wants and contribute to our enjoyments. Nature spontaneously furnishes the matter of which all commodities are made; but until labour has been applied to appropriate that matter, or to

* Economy, from οικος, *a house or family*, and νομος, *a law*. Hence, political economy may be said to be to the state what private economy is to a single family.

adapt it to our use, it is wholly destitute of value, and is not, nor ever has been, considered as forming wealth. Were we placed on the banks of a river, or in an orchard, we should infallibly perish of thirst or hunger, unless by an effort of industry we raised the water to our lips, or plucked the fruit from its parent tree. It is seldom, however, that the mere appropriation of matter is sufficient. In the vast majority of cases, labour is required not only to appropriate it, but to convey it from place to place, and to give it that peculiar shape without which it may be totally useless, and incapable of administering either to our necessities or our comforts. The coal used in our fires is buried deep in the bowels of the earth, and is absolutely worthless until, by the labour of the miner, it has been extracted from the mine, and brought into a situation where it may be made use of. The stones and mortar used in building our houses, and the rugged and shapeless materials that have been fashioned into the various articles of convenience and ornament with which they are furnished, were, in their original state, destitute alike of value and utility. And of the innumerable variety of animal, vegetable, and mineral products which form the materials of our food and clothes, none were originally serviceable, while many were extremely noxious to man. The labour that has subdued their bad qualities, that has given them utility, and fitted them to satisfy our wants, and to minister to our comforts and enjoyments, is plainly, therefore, the only source of wealth. "Labour," to use the words of Adam Smith, "was the first price, the original purchase-money, that was paid for all things. It was not by gold or by silver, but by labour, that all the wealth of the world was originally purchased."—(*Wealth of Nations*, p. 14.)

Those who observe the progress and trace the history of the human race in different countries and states of society, will find that their comfort and happiness have in all cases been principally dependent on their ability to appropriate the raw products of nature, and to adapt them to their use. The savage whose labour is confined, like that of the Australian, to the gathering of wild fruits, or of shell-fish on the sea-coast, is placed at the very bottom of the scale of civilization, and is, in point of comfort, decidedly inferior to many of the lower animals. The *first* step in the progress of society is made when man learns to hunt wild animals, to feed himself with their flesh, and clothe himself with their skins. But labour, when confined to the chase, is extremely barren and unproductive. Tribes of hunters, like beasts of prey, whom they closely resemble in their habits and modes of subsistence, are but thinly scattered over the countries which they occupy; and notwithstanding the fewness of their numbers, any unusual deficiency in the supply of game never fails to reduce them to the extremity of want. The *second* step in the progress of society is made when the tribes of hunters and fishers devote themselves, like the ancient Scythians and modern Tartars, to the domestication of wild animals and the rearing of flocks. The subsistence of herdsmen and shepherds is much less precarious than that of hunters; but they are almost entirely destitute of the various comforts and elegancies that give to civilized life its chief value. The *third* and most decisive step in the progress of civilization, in the great art of producing the necessaries and conveniences of life, is made when the wandering tribes of hunters and shepherds renounce their migratory habits, and become agriculturists and manufacturers. It is then that man begins fully to avail himself of his productive powers. He then becomes laborious, and by a necessary consequence his wants are then, for the first time, fully supplied, and he acquires an extensive command over the articles necessary for his comfort as well as his subsistence.

The importance of labour in the production of wealth was very clearly perceived by Locke. In his *Essay on Civil Government*, published in 1689, he has entered into a lengthened, discriminating, and able analysis, to show that it is from labour that the products of the earth derive almost all their value. "Let any one consider," says he, "what the difference is between an acre of land planted with tobacco or sugar, sown with wheat or barley, and an acre of the same land lying in common, without any husbandry upon it, and he will find that the improvement of labour makes the far greater part of the value. I think it will be but a very modest computation to say, that of the products of the earth useful to the life of man, *nine tenths* are the effects of labour; nay, if we will rightly estimate things as they come to our use, and cast up the several expenses about them, what in them is purely owing to nature, and what to labour, we shall find that in most of them *ninety-nine hundredths* are wholly to be put on the account of labour.

"There cannot be a clearer demonstration of any thing than several nations of the Americans are of this, who are rich in land, and poor in all the comforts of life; whom nature having furnished as liberally as any other people with the materials of plenty, *i.e.* a fruitful soil apt to produce in abundance what might serve for food, raiment, and delight; yet, for want of improving it by labour, have not one hundredth part of the conveniences we enjoy; and the king of a large and fruitful territory there feeds, lodges, and is clad worse than a day labourer in England.

"To make this a little clearer, let us but trace some of the ordinary provisions of life through their several progresses before they come to our use, and see how much they receive of their value from human industry. Bread, wine, and cloth are things of daily use and great plenty; yet, notwithstanding, acorns, water, and leaves or skins must be our bread, drink, and clothing, did not labour furnish us with these more useful commodities; for whatever bread is more worth than acorns, wine than water, and cloth or silk than leaves, skins, or moss, that is solely owing to labour and industry: the one of these being the food and raiment which unassisted nature furnishes us with; the other provisions which our industry and pains prepare for us; which how much they exceed the other in value when any one hath computed, he will then see how much labour makes the far greatest part of the value of things we enjoy in this world. And the ground which produces the materials is scarce to be reckoned in as any, or at most but a very small part of it; so little, that even amongst us, land that is wholly left to nature, that hath no improvement of pasturage, tillage, or planting, is called, as indeed it is, *waste;* and we shall find the benefit of it amount to little more than nothing.

"An acre of land that bears here twenty bushels of wheat, and another in America which, with the same husbandry, would do the like, are, without doubt, of the same natural intrinsic value (utility). But yet the benefit mankind receives from the one in a year is worth five pounds, and from the other possibly not worth a penny, if all the profit an Indian received from it were to be valued and sold here; at least, I may truly say, not one thousandth. It is labour, then, which puts the greatest part of value upon land, without which it would scarcely be worth anything. It is to that we owe the greatest part of all its useful products; for all that the straw, bran, bread, of that acre of wheat, is more worth than the product of an acre of as good land which lies waste, is all the effect of labour. For it is not barely the ploughman's pains, the reaper's and thrasher's toil, and the baker's sweat is to be accounted into the bread we eat; the labour of those who broke the oxen, who digged and wrought the iron and stones, who felled and framed the timber employed about the plough, mill, oven, or any other utensils, which are a vast number, requisite to this corn; from its being seed to be sown to its being made bread must all be charged on the account of *labour*, and received as an effect of that, nature and the earth furnished only the almost worthless materials as in themselves. It would be a strange catalogue of things that industry provided and made use of about every loaf of bread before it came to our use, if we could trace them; iron, wood, leather, bark, timber, stone, bricks, coals, lime, cloth, dyeing drugs, pitch, tar, masts, ropes, and all the materials made use of in the ships that brought away the commodities made use of by any of the workmen to any part of the work; all which it would be almost impossible, at least too long, to reckon up."

Mr. Locke has here all but established the fundamental principle upon which this science rests. Had he carried his analysis a little further, he could not have failed to perceive that neither water, leaves, skins, nor any one of the spontaneous products of nature, has any *value*, except what it owes to the labour required for its appropriation. The utility of such products makes them be demanded, but it does not give them value; this is a quality which can be communicated only through the agency of voluntary labour of some sort or other. An object which it does not require any portion of labour to appropriate, or to adapt to our use, may, like atmospherical air, be of the very highest utility; but as it is the free gift of nature, it is quite impossible it should have the smallest value.

That commodities could not be produced without the co-operation of the powers of nature, is most certain. We are very far, indeed, from wishing to depreciate the obligations we are under to our common mother, or to exalt the benefits man owes to his own exertions by concealing or underrating those which he enjoys through the bounty of nature. But it is the distinguishing characteristic of the services rendered by the latter, that they are *gratuitous*. They are infinitely useful, and they are, at the same time, infinitely cheap. They are not, like human services, sold for a price; they are merely appropriated. When a fish is caught, or a tree is felled, do the Nereids, or wood nymphs, make their appearance, and stipulate that the labour of nature in producing it should be paid for, before it be carried off and made use of by man? When the miner has dug his way down to the ore, does Plutus interpose to prevent its appropriation? Nature is not, as so many would have us to suppose, frugal and grudging. Her rude products, and her ca-

pacities and powers, are all offered freely to man. She neither demands nor receives a return for her favours. Her services are of inestimable *utility;* but being granted freely and unconditionally, they are wholly destitute of value, and are consequently without the power of communicating that quality to any thing.

The utility of water, or its capacity to slake thirst, is equal at all times and places; but as this quality is communicated to it by nature, it adds nothing to its value, which is, in all cases, measured by the labour required for its appropriation. A very small expenditure of labour being required to raise water from a river to the lips of an individual on its banks, its value, under such circumstances, is very trifling indeed. But when, instead of being upon its banks, the consumers of the water are five, ten, or twenty miles distant, its value, being increased proportionally to the greater expenditure of labour upon its conveyance, may become very considerable. This principle holds universally. The utility of coal, or its capacity of furnishing heat and light, makes it an object of demand; but this utility, being a free gift of nature, has no influence over its value or price: this depends entirely on the labour required to extract the coal from the mine, and to convey it to the consumers.

"Si je retranche," to use a striking illustration of this doctrine given by M. Canard, "de ma montre, par la pensée, tous les travaux qui lui ont été successivement appliqués, il ne restera que quelques grains de minéral placés dans l'intérieur de la terre, d'où on les a tirés, et où ils n'ont aucune valeur. De même, si je décompose le pain que je mange, et que j'en retranche successivement tous les travaux successifs qu'il a reçus, il ne restera que quelques tiges d'herbes graminées, éparsés dans des déserts incultes, et sans aucune valeur."

It is true, that natural powers and products may sometimes be appropriated or engrossed by one or more individuals to the exclusion of others, and those by whom they are so engrossed may exact a price for them; but does that show that they cost the engrossers any thing? If A. have a waterfall on his estate, he may, probably, get a rent for it. It is plain, however, that the work performed by the waterfall is as completely gratuitous as that which is performed by the wind that acts on a windmill. The only difference between them originates in this, — that all individuals having it in their power to avail themselves of the services of the wind, no one can intercept the bounty of nature, and exact a price for that which she freely bestows; whereas A., by appropriating the waterfall, and consequently acquiring a command over it, has it in his power to prevent its being used at all, or to sell its services. He can oblige B., C., and D. to pay for liberty to use it; but as they pay for that which costs him nothing, he gains the *whole* that they lose; so that the services rendered by the waterfall are still so much clear gain — so much work performed gratuitously for society.

Had Mr. Senior attended to this principle, he would not have made the strange supposition, that if aerolithes consisted wholly of gold, they would, according to the principles now explained, be destitute of value.* If, indeed, they were so very abundant as to supply every one with as much gold as he desired, they would have no value whatever, other than what they might derive from the trouble of gathering them, but, if they existed only in limited quantities, and were quite incapable of supplying the demand for gold, the fortunate finder of one of them would be able to sell it, or exchange it, for the same quantity of produce it would have commanded had it been produced, like other gold, by the labour of the miner, smelter, &c. But it is obvious that its value is in this case derived from circumstances which, though extrinsic to itself, depend wholly on the expenditure of labour; and that, in fact, it is measured or determined by the labour required to produce gold under ordinary circumstances, precisely in the same way that the value of the waterfall is determined by the quantity of labour it will save to the party by whom it is bought or rented.

Labour, therefore, is the sole source of exchangeable value, and, consequently, of wealth. It is the talisman that has raised man from the condition of the savage — that has changed the desert and the forest into cultivated fields; that has covered the earth with cities, and the ocean with ships; that has given us abundance, comfort, and elegance, instead of want, misery, and barbarism: —

> "All is the gift of Industry; whate'er
> Exalts, embellishes, and renders life
> Delightful.

The fundamental principle, that it is only through the agency of labour that the various articles and conveniences required for the use and accommodation of man can be obtained, being thus established, it necessarily follows, that the great practical problem involved in that part of the science which treats of the *production* of wealth must resolve itself into a discussion of the means by which labour may be rendered most efficient. Every measure that has any tendency to add to the power of labour, or, which is the same thing, to reduce the cost of commodities, must add proportionally to the means of obtaining wealth and riches; while every measure or regulation that has any tendency to waste labour, or to raise the cost of commodities, must equally lessen these means. This, then, is the simple and decisive test by which to judge of the expediency of all measures affecting the wealth of a country, and of the value of all inventions. If they render labour more productive, — if, by reducing the value of commodities, they render them more easily obtainable, and bring them within the command of a greater portion of society, they must be advantageous; and conversely. Considered in this point of view, that great branch of the science which treats of the *production* of wealth will be found to be abundantly simple, and easily understood.

Labour, according as it is applied to the raising of raw produce, to the fashioning of that raw produce when raised into articles of utility, convenience, or ornament, or to the conveyance of raw and wrought produce from one country or place to another, is said to be agricultural, manufacturing, or commercial. An acquaintance with the particular processes, and most advantageous methods of applying labour in each of these grand departments of industry, forms the peculiar and appropriate study of agriculturists, manufacturers, and merchants. It is not consistent with the objects of the political economist to enter into the details of particular businesses and professions. He confines himself to an investigation of the means by which labour in general may be rendered most productive, and how its powers may be increased in *all* the departments of industry.

In thus endeavouring to exhibit the importance of labour, and the advantages which its successful prosecution confers on man, it must not be supposed that reference is made to the labour of the hand only. This species, indeed, comes most under our observation: it is that, too, without which we could not exist, and which principally determines the value of commodities. It is questionable, however, whether it be really more productive than the labour of the mind. The hand is not more necessary to execute than the head to contrive. Some very valuable discoveries have no doubt been the result of accident; while others have naturally grown out of the progress of society, without being materially advanced by the efforts of any single individual. These, however, have not been their only, nor, perhaps, their most copious sources; and every one, how little soever he may be acquainted with the history of his species, is aware that we are indebted to the labour of the mind, to patient study and long-continued research, for numberless inventions, some of which have made almost incalculable additions to our powers, and changed, indeed, the whole aspect and condition of society.

2. *Means by which Labour may be facilitated.* — Having thus endeavoured to show that man is indebted to labour or industry for all those articles or products which constitute wealth, or which are not freely bestowed by nature, we have next to inquire into the means by which labour may be rendered most productive, or by which the greatest amount of wealth may be obtained with the least labour, or at the least expense.

It may seem on a cursory view as if an inquiry of this sort would necessarily branch out into an infinity of details. But, in so far as this science, which deals only with the general principles applicable to all departments of industry, is concerned, such is not the case. On the contrary, it will be found, supposing the security of property, without which there can be neither industry nor accumulation, to be established, that all the means by which labour may be facilitated and wealth increased resolve themselves, 1st, into the better division and combination of employments among individuals and nations; and, 2d, into the more extensive or more judicious application of capital or stock in industrious undertakings. All the improvements that ever have been or ever will be made in the great art of producing the various necessaries, conveniences, and enjoyments of human life may be classed under one or other of these heads; that is, they will be found to consist either in the better distribution of employments, or in the greater command and better application of capital. Without availing themselves of these means no people can make any advance in civilization. And, supposing property to be equally well protected, it will, generally speaking, be found that those nations have been the wealthiest, most cultivated, and refined, in which the division of labour has been carried to the farthest extent, and capital been most abundant and most judiciously applied.

Division of Employments. — The division of employments can only be imperfectly established in rude societies and thinly-peopled countries; but in every state of society — in the rudest as well as the most improved — we may trace its operation and effects. The various physical powers, talents, and propensities, with which men are endowed, fit them for different occupations; and a

* Art. "Political Economy," *Encyclopædia Metropolitana.*

regard to mutual interest and convenience naturally leads them, at a very early period, to establish a system of barter and a division of employments. It was speedily seen that by separating and combining their efforts so as to bring about some desirable end, they might, with ease, accomplish tasks that could not otherwise be attempted. Even in the simplest businesses this co-operation is required: neither hunting nor fishing, any more than agriculture or manufactures, can be advantageously carried on by solitary individuals. Man is the creature of society; and is compelled, in every stage of his progress, to, depend for help on his fellows: — *Quò alio fortes sumus quàm quòd mutuis juvamur officiis?* Instead of trusting to his own unaided efforts for a provision of the various articles required for his subsistence, comfort, and security, he instinctively associates himself with others, and finds in this association the principal source of his superior power. Perceiving that he can obtain an incomparably greater command of all that he deems useful or desirable by applying himself in preference to some one department of industry, he limits his attention to it only. As society advances, this division extends itself on all sides: one man becomes a tanner or dresser of skins; another a shoemaker; a third a weaver; a fourth a house-carpenter; a fifth a smith, and so on; one undertakes the defence of the society, and one the distribution of justice; and each endeavours to cultivate and bring to perfection whatever talent or genius he may possess for the particular calling in which he is engaged. The wealth and comforts of all classes are, in consequence, prodigiously augmented. In countries where the division of labour is carried to a considerable extent, agriculturists are not obliged to spend their time in clumsy attempts to manufacture their own produce, and manufacturers cease to interest themselves about the raising of corn, and the fattening of cattle. The facility of exchanging is the vivifying principle of industry; it stimulates agriculturists to adopt the best system of cultivation, and to raise the largest crops, because it enables them to exchange whatever portion of the produce of their lands exceeds their own wants for other commodities contributing to their comforts and enjoyments; and it stimulates manufacturers and merchants to increase and improve the quantity, variety, and quality of their goods, that they may thereby obtain greater supplies of raw produce. A spirit of industry is thus universally diffused; and that apathy and languor which characterize a rude state of society entirely disappear.

But the facility of exchanging, or the circumstance of being able readily to barter the surplus produce of our own labour for such parts of the surplus produce of other people's labour as we may desire to obtain and they may choose to part with, is not the only advantage of the separation of employments. Besides enabling each individual to addict himself in preference to those departments which suit his taste and disposition, it adds very largely to the efficacy of his powers, and enables him to produce a much greater quantity of useful and desirable articles than he could do were he to engage indiscriminately in different businesses. Dr. Smith, who has treated this subject in the most masterly manner, has classed the circumstances which conspire to increase the productive powers of industry, when labour is divided, under the following heads: — *First*, the increased skill and dexterity of the workmen; *second*, the saving of time which is commonly lost in passing from one employment to another; and, *third*, the circumstance of the division of employments having a tendency to facilitate the invention of machines and processes for abridging and saving labour. A few observations on each of these heads are subjoined.

1st. *With respect to the improvement of the skill and dexterity of the labourer.* — It is sufficiently plain that when a person's whole attention is devoted to one branch of business, when all the energies of his mind and powers of his body are made to converge, as it were, to a single point, he must attain to a degree of proficiency in that particular branch, to which no individual engaged in a variety of occupations can be expected to reach. A peculiar play of the muscles, or *sleight of hand*, is necessary to perform the simplest operation in the best and most expeditious manner, and this can only be acquired by habitual and constant practice. Smith has given a striking example, in the case of the nail-manufacturer, of the extreme difference between training a workman to the precise occupation in which he is to be employed, and training him to a similar and closely allied occupation. " A common smith," says he, " who, though accustomed to handle the hammer, has never been used to make nails, if, upon some particular occasion, he is obliged to attempt it, will scarce, I am assured, be able to make above two or three hundred nails in a day, and those, too, very bad ones. A smith who has been accustomed to make nails, but whose sole or principal business has not been that of a nailer, can seldom, with his utmost diligence, make more than eight hundred or a thousand nails in a day. But I have seen several boys, under twenty years of age, who had never exercised any other trade but that of making nails, and who, when they exerted themselves, could make, each of them, upwards of *two thousand three hundred nails in a day*, or nearly three times the number of the smith who had been accustomed to make them, but who was not entirely devoted to that particular business." (*Wealth of Nations*, p. 4.)

2d. The influence of the division of labour in preventing that *waste of time in moving from one employment to another*, which must always take place when an individual engages in different occupations, is even more obvious than its influence in improving his skill and dexterity. When the same person carries on different employments, in different and perhaps distant places, and with different sets of tools, he must plainly lose a considerable portion of time in passing between them. If the different employments in which he is to be engaged could be carried on in the same workshop, the loss of time would be less; but even in that case it would be considerable. " A man," as Dr. Smith has justly observed, " commonly saunters a little in turning his hand from one sort of employment to another. When he first begins the new work, he is seldom very keen and hearty; his mind, as they say, does not go along with it, and for some time he rather trifles than applies to good purpose. The habit of sauntering and of indolent careless application, which is naturally, or rather necessarily, acquired by every country workman, who is obliged to change his work and his tools every half hour, and to apply his hand in twenty different ways almost every day of his life, renders him almost always slothful and lazy, and incapable of any vigorous application, even on the most pressing occasions. Independent, therefore, of his deficiency in point of dexterity, this cause alone must always reduce considerably the quantity of work which he is capable of performing." (*Wealth of Nations*, p. 5.)

3d. *With regard to the influence of the division of employments in facilitating the invention of machines, and processes for abridging and saving labour.* — It is obvious that those engaged in any branch of industry will be more likely to discover easier and readier methods of carrying it on when the whole attention of their minds is devoted exclusively to it, than if it were dissipated among a variety of objects. But it is a mistake to suppose, as has been sometimes done, that the inventive genius of workmen and artificers is alone whetted and improved by the division of labour. As society advances, the study of particular branches of science and philosophy becomes the principal or sole occupation of the most ingenious men. Chemistry becomes a distinct science from natural philosophy; the physical astronomer separates himself from the astronomical observer; the political economist from the politician; and each, meditating exclusively or principally on his peculiar department of science, attains to a degree of proficiency and expertness in it which the general scholar seldom or never reaches. And hence, in labouring to promote our own ends, we all necessarily adopt that precise course which is most advantageous for all. Like the different parts of a well-constructed engine, the inhabitants of a civilized country are all mutually dependent on and connected with each other. Without any previous consent, and obeying only the powerful and steady impulse of self-interest, they universally conspire to the same great end; and contribute, each in his respective sphere, to furnish the greatest supply of necessaries, luxuries, conveniences, and enjoyments.

Probably, however, the most advantageous result of the division of labour may be found in the circumstance of its enabling manufacturers or others engaged in any complicated business, or department of industry, to employ work-people of very various degrees of skill and force. In the cotton manufacture, for example, some processes that are indispensable may be quite as well performed by children and women as by the most expert and powerful workmen. It is clear, however, that but for the distribution of the labour required to bring about any result among different individuals possessing the degree of skill and strength necessary in each particular part of the process, none could be employed but those who possessed the skill and strength required in the most difficult and laborious; and, consequently, workmen at 30*s*. or 40*s*. a week would have to engage in tasks that might be as well or better performed by girls at 5*s*. or 6*s*. a week. In all the great departments of industry it is of the utmost importance to separate the processes requiring peculiar skill, dexterity, and force from the others, and to appropriate them exclusively to certain classes of individuals; and to perform the operations requiring less skill, or less strength, by sets of inferior labourers. The success of most industrious undertakings depends, in fact, principally on the sagacity with which this distribution of employments is made, or with which the skill and power of the work-people are proportioned to the results to be produced. (For further illustrations of this principle see *Babbage's Economy of Manufactures*, p. 172. &c.)

It is necessary to bear in mind that the advantages derived from the division of labour, though they may be, and in fact are, partially enjoyed in every country and state of society, can only be carried to their full extent where there is a great power of exchanging, or an *extensive market*. There are an infinite variety of employments which cannot be separately carried on without the precincts of a large city; and in all cases the division becomes more perfect, according as the demand for the produce is extended. It is stated by Dr. Smith that ten labourers, employed in different departments in a pin manufactory, can produce 48,000 pins a day, and since his time the quantity has been more than doubled; but it is evident that if the demand were not sufficient to take off this quantity, ten persons could not be constantly employed in the business; and the division of employments in it not being carried so far, the labour would be less economically and efficiently applied, and the cost of the pins proportionally increased. The same principle holds universally. A cotton mill could not be constructed in a small country having no intercourse with its neighbours. The demand and competition of Europe, Asia, and America have been necessary to carry the manufactures of Glasgow, Manchester, and Birmingham to their present state of improvement.

Territorial Division of Labour, or Commerce. — Besides that sort of division of labour which enables each individual in a limited society to confine himself to a particular employment, there is another and most important branch of the division of labour, which not only enables particular individuals, but the inhabitants of entire districts, and even nations, to addict themselves in preference to certain branches of industry. It is on this *territorial division of labour*, as it has been appropriately termed, that the commerce carried on between different districts of the same country, and between different countries, is founded. The variations in the situation, soil, climate, mineral products, &c. of the different districts of an extensive country, render them more suitable for some than for other species of industry. A district where coal is abundant, which has an easy access to the ocean, and a considerable command of internal navigation, is the natural seat of manufactures. Wheat and other species of grain are the proper products of rich arable soils; and cattle, after being reared in mountainous districts, are most advantageously fattened in meadows and low grounds. Nothing can be more obvious than that the inhabitants of these different districts will be able, by confining themselves to those employments for the prosecution of which they have some peculiar capability, to produce a much greater quantity of useful and desirable articles than they could do were they to engage indiscriminately in every possible employment. Can it be doubted that a vastly greater supply of manufactured goods, corn, and cattle is produced by the inhabitants of Glasgow, the Carse of Gowrie, and Argyleshire respectively confining themselves to manufactures, agriculture, and the rearing of cattle, than if each endeavoured directly to raise these various products?

But it is easy to see that foreign trade, or the territorial division of labour between different and independent countries, contributes to increase the wealth of each in precisely the same manner that the trade between different provinces of the same kingdom contributes to increase their wealth. There is a still greater difference between the productive powers with which Providence has endowed different and distant countries, than there is between the productive powers of the provinces of the same country; and consequently the establishment of a free intercourse between them must be proportionally more advantageous. Indeed, there are a great many products, and some of them of the very greatest utility, that cannot be raised, except in particular situations. Were it not for commercial intercourse, we should not be able to obtain the smallest supply of tea, spices, raw cotton, raw silk, gold and silver, and a thousand other equally useful and desirable commodities. Providence, by giving different soils, climates, and natural productions to different countries, has evidently provided for their mutual intercourse and civilization. By permitting the people of each to employ their capital and labour in those departments in which their geographical situation, the physical capacities of their soil, their national character and habits fit them to excel, foreign commerce, or the territorial division of labour, has a wonderful influence in multiplying the products of arts and industry. Where the freedom of commerce is not interfered with, each country necessarily devotes itself to such employments as are most beneficial for itself. And this pursuit of individual advantage is in the highest degree conducive to the good of the whole. By stimulating industry, by rewarding ingenuity, and by using most efficaciously the particular powers bestowed by nature, commerce distributes labour most effectively and economically; while by increasing the mass of necessary and useful products it diffuses opulence, and binds together the universal society of nations by the common and powerful ties of mutual interest and reciprocal obligation. Commerce enables each particular state to profit by the inventions and discoveries of every other state. It creates new tastes and new appetites, and it also gives the means and the desire of gratifying them. The progress of domestic industry is accelerated by the competition of foreigners. Commerce has either entirely removed or greatly weakened a host of unworthy prejudices. It has shown that nothing can be more illiberal and absurd than that once prevalent dread of the progress of others in wealth and civilization; and that the true glory and real interest of each particular people will be more certainly advanced by endeavouring to emulate and outstrip its neighbours in the career of science and civilization, than by labouring to attain a barren pre-eminence in the bloody and destructive though necessary art of war.

The influence of commerce in giving increased efficacy to labour, and augmenting national wealth, may be easily illustrated. Thus in the case of the intercourse or territorial division of labour carried on between England and Portugal, our superior wool, and our command of coal, of skilful workmen, of improved machinery, in short, of all the instruments of manufacturing industry, enable us to produce cloth at a much cheaper rate than the Portuguese; but, on the other hand, the soil and climate of Portugal being peculiarly favourable for the cultivation and growth of the grape, she is able to produce wine at an infinitely less cost than it can be produced here. And hence it is obvious that England, by confining herself to the manufacture of cloth, in which she has a natural advantage, and exchanging it with the Portuguese for wine, will obtain a vastly larger supply of that commodity than if she attempted to cultivate the grape at home; and Portugal, by exchanging her wine for the cloth of England, will obtain a much greater quantity of cloth than if she attempted to counteract the intention of nature by converting a portion of her capital and industry from the raising of wine, in which she has an advantage, to the manufacture of cloth, in which the advantage is on the side of another.

What has been already stated is sufficient to expose the sophism of the French economists, who contended, that as an equivalent must be always given for commodities brought from abroad, it is impossible foreign commerce should be a means of increasing wealth. "How," they asked, "can the wealth of a country be increased by giving equal values for equal values?" They admitted that commerce might be the means of making a better distribution of the wealth of the world; but as it did nothing more than exchange one sort of wealth for another, they denied that it could make any addition to its amount. At first sight, this sophistical and delusive statement appears sufficiently conclusive; but a very few words will be sufficient to demonstrate its fallacy. The advantage of commerce does not consist in its enabling either of the parties who carry it on to obtain articles of greater value than those they give in exchange. It may have cost as much to produce the cloth with which the English merchant purchases the wine of Portugal as it did to produce the latter, or it may have cost more. But then it must be observed that in making the exchange the value of the wine is estimated by what it takes to produce it in Portugal, which has peculiar capabilities for that species of industry, and not by what it would take to produce it in England were the trade put an end to; and, in like manner, the value of the cloth is estimated by what it takes to produce it in England, and not by what it would take to produce it in Portugal. The advantage of the intercourse consists in this, that it enables each country to obtain commodities for the production of which it has no natural capability, and which it would therefore cost vastly more to produce directly at home, at the price required to produce them under the most favourable circumstances, and with the least possible expense. The gain of the one party is not the loss of the other. Both benefit by the intercourse, for it enables both to save labour and expense in the production of commodities; so that the wealth of the two countries is not only better distributed, but is also greatly increased, by the territorial division of labour established between them.

"The commerce of one country with another is merely an extension of that division of labour by which so many benefits are conferred on the human race. As the same country is rendered richer by the trade of one province with another; as its labour becomes thus infinitely more divided and more productive than it could otherwise have been; and as the mutual interchange of all those commodities which one province has, and another wants, multiplies the accommodations and comforts of the whole, and the country becomes thus in a wonderful degree more opulent and happy: so the same beautiful train of consequences is observable in the world at large, — that vast empire, of which the different kingdoms may be regarded as the provinces. In this magnificent empire, one province is favourable to the production of one species of produce, and another province to another. By their

mutual intercourse, mankind are enabled to distribute their labour as best fits the genius of each particular country and people. The industry of the whole is thus rendered incomparably more productive; and every species of necessary, useful, and agreeable accommodation is obtained in much greater abundance, and with infinitely less expense." (*Mill's Commerce Defended*, p. 38.)

The supply of a great city with its various articles of provision and consumption affords, as has been justly observed, one of the most striking instances of the benefits resulting from the division and combination of employments on the most extensive scale. In illustration of this, it may be stated, that at this moment (1841), there are not less than two millions of inhabitants congregated within ten miles round St. Paul's, comprising a large proportion of the wealthiest individuals in the kingdom. The production of the provisions and other accommodations required by this vast population employs not only a very large proportion of the people of the United Kingdom, but also an immense number of labourers in the most distant countries. The Chinese furnish the tea; the planters of Jamaica and Demerara the sugar and coffee; Ceylon and the Eastern Archipelago the spices; the Portuguese and French the wines; the people of Cashmere in Central Asia the shawls; the Australians and Germans the wool; the Americans the cotton; the Italians and Chinese the silk; the Norwegians the lobsters; the Spaniards and the people of the Azores the oranges, and so forth, required for the supply of London. And yet, notwithstanding the extreme diversity of the sources whence they are brought, and of the conditions under which they are produced, every article is supplied to the exact extent to which it is wanted; and every individual in this immense city may get, on the shortest notice, any quantity of any article, how great or how small soever, that he requires. There is no excess at one time, or scarcity at another. The supply of every article is adjusted to the demand with a precision that any one not acquainted with the circumstances would, *à priori*, have pronounced impossible.

And how, it may be inquired, are these astonishing results, this constant and equable supply of infinitely varied wants, brought about? Had government undertaken such a task, it certainly would have exhibited, even with the assistance of a whole army of officers and purveyors, a signal and total failure; but it is now effected with the utmost facility by the efforts of individuals, who, in the prosecution of their own interests, confer inestimable advantages on this great city, and, indeed, enable it to subsist. Every retail dealer is aware of the ordinary or average demand of his customers for the article or articles in which he deals; and in like manner the wholesale dealers, who commission articles of the producers, are each and all aware of the quantity that will be taken off by the retailers, whose agents they are, and of the periods when they will have to be supplied. In this way the aggregate and individual wants of any population, how great soever, come to be accurately known; and the quantity of labour required to supply the different articles of which they stand in need, and no more, is put in motion.

It would be unnecessary, in a work of this kind, to dwell on the advantages resulting to society from the formation of improved roads, canals, and other easy means of communication. At bottom, however, the principal advantage of these consists in the facility which they afford for enabling products to be conveyed from one place to another; that is, for enabling the division of labour between different parts of the country to be carried to the greatest extent. And the same principle that teaches us that it is for the public advantage to construct new and improved roads, and to promote to the utmost the facilities of intercourse between the different parts of the United Kingdom, should teach us to abolish, in as far as practicable, all restrictions on the intercourse with foreign countries, and to give full scope to the territorial division of labour between our people and those of other nations. All the arguments that can be used for the opening of new roads, the throwing of bridges over ravines and rivers, and otherwise improving the means of internal intercourse, apply with but little variation, and with equal force, to the abolition of restrictions on the exportation of native and the importation of foreign produce; the object of the one class of measures as of the other is to facilitate the interchange of the various products of art and industry, and consequently to enable capital and labour to be employed in the channels in which they are sure to be most productive. (*See* the art. COMMERCE in this Dict., and the authorities therein referred to.)

The various provisions made by society for its protection, and for securing and preserving the rights and privileges of individuals, owe their origin to this principle. Government itself is wholly founded on a sense of the advantages resulting from the division of employments. "In the rudest state of society each man relies principally on himself for the protection both of his person and of his property. For these purposes he must be always armed, and always watchful; what little property he has must be moveable, so as never to be far distant from its owner. Defence or escape occupy almost all his thoughts, and almost all his time; and, after all these sacrifices, they are very imperfectly effected. 'If ever you see an old man here,' said an inhabitant of the confines of Abyssinia to Bruce, 'he is a stranger; the natives all die young by the lance.'

"But the labour which every individual who relies on himself for protection must himself undergo is more than sufficient to enable a few individuals to protect themselves, and also the whole of a numerous community. To this may be traced the origin of governments. The nucleus of every government must have been some person who offered protection in exchange for submission. On the governor and those with whom he is associated, or whom he appoints, is devolved the care of defending the community from violence and fraud; and so far as internal violence is concerned, and that is the evil most dreaded in civilized society, it is wonderful how small a number of persons can provide for the security of multitudes. About fifteen thousand soldiers, and not fifteen thousand policemen, watchmen, and officers of justice, protect the persons and property of the seventeen millions of inhabitants of Great Britain. There is scarcely a trade that does not engross the labour of a greater number of persons than are employed to perform this the most important of all services." (*Senior on Political Economy.*)

Definition and Employment of Capital.—The capital of a country consists of those portions of the produce of industry existing in it that may be made directly available, either for the support of human beings, or the facilitating of production. It consequently comprises all those articles that may be employed for the subsistence, clothing, and lodging of the labourers engaged in industrious undertakings; and the various animals, tools, and machines of which they may avail themselves in performing their tasks. It is usual to call the former, or the food, clothes, &c., required for the subsistence of the labourer, the corn used as seed and in the feeding of horses, coal, &c., *circulating* capital; while those articles that are more slowly consumed, as the lower animals, the houses, and the various instruments and machines that either are or may be employed in industrious undertakings, are called *fixed* capital. But though this distinction be convenient for some purposes, no distinct line of demarcation can be drawn between the different varieties of capital, and they are alike indispensable to the successful prosecution of most branches of industry. Without a supply of the first, or circulating capital, that is, without a supply of food, clothes, &c., it would plainly be impossible to engage in any sort of undertaking where the return was at all distant; and without the second, or fixed capital, that is, without the aid of tools and machines (which are merely a more complex species of tools), there are but few sorts of labour that could be carried on at all, or with any advantage. But the progressive nature of man, his foresight and inventive faculty, lead him, even in the earliest ages, and in the rudest states of society, to provide a reserve of food, and to contrive tools and instruments to assist him in his operations. The American hunters make use of clubs and slings to abridge their labour and facilitate the acquisition of game; and the same principle which prompts them to construct and avail themselves of those rude instruments never ceases to operate: it is always producing some new improvement, and in an advanced and refined period substitutes ships for canoes, muskets for slings, steam-engines for clubs, and cotton-mills for distaffs.

Hence it is only by the employment and co-operation of both descriptions of capital that wealth can be largely produced, and universally diffused. An agriculturist might have an ample supply of carts and ploughs, of oxen and horses, and, generally, of all the instruments and animals used in his department of industry; but were he destitute of circulating capital, or food and clothes, he would be unable to avail himself of their assistance; and instead of tilling the ground, would have to resort to some species of appropriative industry: and, on the other hand, supposing he were abundantly supplied with provisions, what could he do without the assistance of a fixed capital, or tools? What could the most skilful husbandman perform without his spade and plough? a weaver without his loom? a carpenter without his saw, his hatchet, and his planes.

The division of labour cannot be carried to any considerable extent without the previous accumulation of capital. Before labour can be divided, "a stock of goods of different kinds must be stored up somewhere, sufficient to maintain the labourer, and to supply him with materials and tools. A weaver cannot apply himself entirely to his peculiar business, unless there is beforehand stored up somewhere, either in his own possession or in that of some other person, a stock sufficient to maintain him, and to supply him with the materials and tools of his works, till he has not only completed but sold his web. This accumulation must, evidently, be previous to his

applying himself for so long a time to such a peculiar business." (*Wealth of Nations*, 119.)

As the accumulation of capital must have preceded the extensive division of labour, so its subsequent division can only be perfected as capital is more and more accumulated. Accumulation and division act and react on each other. The quantity of work which the same number of people can perform increases in a great proportion with every fresh subdivision of labour; and according as the operations of each workman are reduced to a greater degree of identity and simplicity, he has, as already explained, a greater chance of discovering machines and processes for facilitating his separate task. The quantity of industry, therefore, not only increases in every country with the increase of the stock or capital which sets it in motion; but, in consequence of this increase, the division of labour is extended, new and more powerful implements and machines are invented, and the same quantity of labour is made to produce an infinitely greater quantity of commodities.

Besides enabling labour to be divided, capital contributes to facilitate labour and produce wealth in the three following ways:—

First. — It enables work to be executed that could not be executed, or commodities to be produced that could not be produced, without it.

Second. — It saves labour in the production of almost every species of commodities.

Third. — It enables work to be executed better, as well as more expeditiously.

With regard to the first advantage derived from the employment of capital, or the circumstance of its enabling commodities to be produced that could not be produced without it, it is plain, as already observed, that the production of such commodities as require a considerable period for their completion could not be attempted unless a stock of circulating capital, or of food and clothes sufficient for the maintenance of the labourer while employed on them, was previously provided. But the possession of fixed capital, or of tools and machines, is frequently as necessary to the production of commodities as the possession of circulating capital. It would, for example, be quite impossible to produce a pair of stockings without the aid of wires; and although the ground might be cultivated without the aid of a plough, it could not be cultivated without the aid of a spade or a hoe. If we run over the vast catalogue of the arts practised in a civilized country, it will be found that extremely few can be carried on by the mere employment of the fingers, or rude tools with which man is furnished by nature. It is almost always necessary to provide ourselves with the result of previous industry and invention, and to strengthen our feeble hands by arming them, if we may so speak, "with the force of all the elements."

In the second place, besides supplying many species of commodities that could not be produced without its co-operation, the employment of capital occasions a saving of labour in the production of many others; and, by lowering their cost, brings them within the reach of a far greater number of consumers. We have been so long accustomed to profit by the services of the most commodious and powerful machines, that it requires a considerable effort of abstraction to become fully aware of the advantages we owe to them. But if we compare the arts practised alike by highly civilized societies and those in a less advanced state, we can hardly fail of being convinced that we are indebted to the employment of machinery for a very large proportion of our superior comforts and enjoyments. Suppose, that, like the Peruvians, and many other people of the New as well as the Old World, we were destitute of iron, and unacquainted with the method of domesticating and employing oxen and horses, how prodigious a change for the worse would be made in our condition! It was customary, in some countries, to make cloth by taking up thread after thread of the warp, and passing the woof between them by the unassisted agency of the hand; so that years were consumed in the manufacture of a piece which, with the aid of the loom, may be produced in as many days. Nothing, perhaps, has contributed so much to accelerate the progress and diffuse the blessings of civilization, as the establishment of a commercial intercourse between different and distant nations. But how could this be effected without the construction of vessels, and the discovery of the art of navigation? And if we compare the early navigators, creeping timidly along the shore in canoes formed out of trees partly hollowed by fire, and partly by the aid of a stone hatchet or the bone of some animal, with those who now boldly traverse the trackless ocean in noble ships, laden with the produce of every climate, we shall have a faint idea of the advance of the arts, and what we owe to machinery and science. Those who have distinguished themselves in this career, though they have rarely met with that gratitude and applause from their fellow-citizens to which they had so just a claim, have been the great benefactors of the human race. By pressing the powers of nature into our service, and subjecting them to our control, they have given man almost omnipotent power, and rendered him equal to the most gigantic undertakings. Without their assistance we should be poor indeed! Such as the naked and half-famished savage of New Holland is at this day, such would the Athenian, the Roman, and the Englishman have been, but for the invention of tools and machines, and the employment of natural agents in the great work of production.

The *third* advantage derived from the employment of capital consists in its enabling work to be done *better*, as well as more expeditiously. Cotton, for example, might be spun by the hand; but the admirable machines invented by Hargreaves, Arkwright, and others, enable a hundred or a thousand times as much yarn to be spun as could be effected by means of a common spindle, at the same time that they have improved its quality and given it a degree of fineness and of evenness, or equality in its parts, which was never previously attained. A painter would occupy months, or it might be years, in painting with a brush the cottons, or printed cloths, used in the hanging of a single room; and it would be very difficult, if not impossible, for the best artist to give that perfect identity to his figures which is given to them by the machinery now made use of for that purpose. Not to mention the other and more important advantages resulting from the invention of moveable types and printing, it is certain that the most perfect manuscript, one on which years of patient and irksome labour have been expended, is unable, in point of delicacy and correctness, to match a well-printed work, executed in the hundredth part of the time, and at a hundredth part of the expense. The great foreign demand for English manufactured goods results no less from the superiority of their manufacture than from their greater cheapness; and for both these advantages we are principally indebted to the excellence of our machinery.

There are other considerations which equally illustrate the extreme importance of the accumulation and employment of capital. The food and other accommodations enjoyed by a nation cannot be increased except by an increase in the number of its labourers, or in their productive powers; but, without an increase of capital, it is in most cases impossible to employ more workmen with advantage If the articles applicable to the support of the labourers, and the tools and machines with which they are to operate, be required for the maintenance and efficient employment of those already in existence, there can be no additional demand for others. Under such circumstances the rate of wages cannot rise; and if the number of inhabitants be increased, they must be worse provided for. Neither is it at all probable that the powers of the labourer should be augmented, except capital be previously increased. Without the better education and training of workmen, the greater subdivision of their employments, or the improvement of machinery, their productive energies can never be materially increased; and in almost all these cases additional capital is required. It is seldom, unless by its means, that workmen can be better trained, or that the undertaker of any work can either provide them with better machinery, or make a proper distribution of labour among them. Should the work to be done consist of a number of parts, to keep a workman constantly employed in one only requires a much larger stock than when he is occasionally employed in every different part. "When," says Dr. Smith, "we compare the state of a nation at two different periods, and find that the annual produce of its land and labour is evidently greater at the latter than at the former, that its lands are better cultivated, its manufactures more numerous and more flourishing, and its trade more extensive, we may be assured that its capital must have increased during the interval between these two periods, and that more must have been added to it, by the good conduct of some, than had been taken from it, either by the private misconduct of others, or by the public extravagance of government." (*Wealth of Nations*, 152.) It is therefore apparent that no country can ever reach the stationary state, so long as she continues to accumulate additional capital. While she does this she will have an increased demand for labour, and will be uniformly augmenting the mass of necessaries, luxuries, and conveniences, and consequently, also, the numbers of her people. But with every diminution of the rate at which capital has been accumulating, the demand for labour will decline. When no additions are made to capital, no more labour will be, or, at least, can be advantageously employed. And should the national capital diminish, the condition of the great body of the people will deteriorate; the wages of labour will be reduced; and pauperism, with its attendant train of vice, misery, and crime, will spread its ravages throughout society.

Objections to Machinery unfounded. — But, admitting what has been stated, still it may be, and indeed has been contended, that how advantageous soever to the country, machines, on their first introduction, frequently injure the labouring class, by lessening the demand for labour and

the rate of wages. In point of fact, however, it admits of demonstration that every introduction of improved machinery is sure to increase the aggregate demand for labour; at the same time that, by reducing the cost of commodities, it enables the labouring class, in common with the rest of society, to obtain a greater command over necessaries and conveniences. It sometimes, indeed, happens that the introduction of machinery is injurious to the labourers employed in a particular department; but if it displace them, it cannot fail to occasion a more than equivalent demand for their services in other departments. The introduction of moveable types and printing threw out of employment all those who had been previously engaged in the copying of manuscripts; but, at the same time, it is certain that this invention, by cheapening and multiplying books, has made at least from a hundred to five hundred persons be employed in the book trade for one that was employed in it when it began to be introduced, or that would have been employed in it at this moment had it not been discovered.

Precisely similar results follow in all cases in which any peculiar description of hand labour is superseded by machinery. At this moment we have an example of the principle before us in the business of hand-loom weaving, which is in the course of being superseded by the introduction of power-looms, the hand-loom weavers being, like the copying clerks in the 15th and 16th centuries, involved in the greatest difficulties. But these, how severe soever in the meantime, will be but of temporary duration, and society will be perpetual gainers by the change. Power-looms are introduced only because they do their work cheaper than it can be done by the hand. But the wealth of those who buy the products of the power-looms is not affected by the change; and whatever they may save through the reduction of their price will be laid out on other things, the production of which will, in the end, fully absorb the unemployed hand-loom weavers, at the same time that the cheapened products will be brought within the command of new classes of purchasers, and that the demand for them will be proportionally increased; and this, it is plain, will open a new field for the employment of many additional hands in the construction of machinery, and in the various subordinate departments connected with the manufacture. To suppose, indeed, that the introduction of improved machinery should, under any circumstances, entail a real injury on society, is to suppose what is contradictory and absurd; it is equivalent to supposing that society might be injured by an increased productiveness of soil, and an increased salubrity of climate; it is to suppose that wealth may be too much increased, and that the necessaries and conveniences of life may be too widely diffused.

Circumstances most favourable for the Accumulation of Capital.—Having thus endeavoured to point out the vast importance of the employment of capital, and the manner in which it co-operates in facilitating production, we proceed to explain the circumstances most favourable for its accumulation. Now, as capital is nothing but the accumulated produce of previous industry, it is evident that its increase will be most likely to be most rapid where industry is most productive; or, in other words, where the profits of stock are highest. The man who can produce a bushel of wheat in three days may accumulate twice as fast as the man who, either from a deficiency of skill, or from having to cultivate a bad soil, is forced to labour six days to produce the same quantity; and the capitalist who can invest stock so as to yield him a profit of ten per cent., has it equally in his power to accumulate twice as fast as he who can only obtain five per cent. for his capital. Experience, too, shows, that while high profits afford greater means of saving, they act as incentives to accumulation. Hence it is found that in those countries most rapidly increasing in wealth and population, the rate of profit is always comparatively high. Thus in the United States, the rate of profit is usually twice as high as in Great Britain or France; and it is to this that the more rapid advancement of the former in wealth and population is entirely to be ascribed. We do not mean to say that high profits are necessarily, and in every instance, accompanied by a great degree of prosperity. Countries with every other advantage for the profitable employment of industry and stock may be subjected to a despotical government, which does not respect the right of property; and the want of adequate security thence resulting may be sufficient to paralyse all the exertions of those who are otherwise placed in the most favourable situation for the accumulation of capital. But we have no hesitation in laying it down as a principle which holds in every case, and from which there is really no exception, that if the governments of any two or more countries be about equally liberal, and property in each be about equally well secured, their comparative prosperity will depend on the rate of profit: wherever profits are high, there is a great demand for labour, and the society rapidly augments both in population and riches. On the other hand, wherever they are low, the demand for labour is proportionally reduced, and the progress of society rendered so much the slower. But however high the rate of profit, had men always lived up to their incomes, that is, had they always consumed the whole produce of their industry in the gratification of their immediate wants and desires, it is obvious there could have been no such thing as capital in the world. High profits are advantageous, because they afford the means of amassing capital; but something more is necessary to make us use these means, and this is the accumulating principle. The desire implanted in the breast of every individual of rising in the world, and improving his condition, has prompted mankind to save a portion of their income, or of the produce of their industry, from immediate consumption, and to set it apart as a fund, or capital, to assist them in their future undertakings. It is to this principle, therefore, or rather to its effect, parsimony, that we owe our capital; and it is to capital that we owe almost all our comforts and enjoyments. Without its assistance and co-operation, labour could not have been divided; arts could not have made any progress; and mankind must have continued to shelter themselves, as in the earliest ages, in caves and forests, and to clothe themselves with the skins of wild animals. All the accumulated riches of the world, the cities which cover its surface, the ships which traverse its seas, and the innumerable variety of improvements, owe their origin to this principle, — to the desire to rise in the world, and consequently to save and amass.

It has been wisely ordered that this principle should be as powerful as it is advantageous. "With regard to profusion," says Smith, "the principle which prompts to expense is the passion for present enjoyment; which, though sometimes violent, and very difficult to be restrained, is, in general, only momentary and occasional. But the principle which prompts to save is the desire of bettering our condition; a desire which, though generally calm and dispassionate, comes with us from the womb, and never leaves us till we go into the grave. In the whole interval which separates the two moments, there is scarce, perhaps, a single instance in which any man is so perfectly and completely satisfied with his situation as to be without any wish of alteration or improvement of any kind. An augmentation of fortune is the means by which the greater part of men propose and wish to better their condition. It is the means the most vulgar and the most obvious; and the most likely way of augmenting their fortune is to save and accumulate some part of what they acquire, either regularly and annually, or upon some extraordinary occasion. Though the principle of expense, therefore, prevails in almost all men upon some occasions, and in some men upon almost all occasions, yet in the greater part of men, taking the whole course of their life at an average, the principle of frugality seems not only to predominate, but to predominate very greatly." (*Wealth of Nations*, 151.)

It is this principle which carries society forward. The spirit of parsimony, and the efforts which the frugal and industrious classes make to improve their condition, in most instances balance not only the profusion of individuals, but also the more wasteful profusion and extravagance of government. The spirit of economy has been happily compared by Smith to the unknown principle of animal life, the *vis medicatrix naturæ*, which frequently restores health and vigour to the constitution, in spite both of disease, and of the absurd prescriptions of the physician.

But however great the capacity of the principle of accumulation to repair the waste of capital, we must take care not to fall into the error of supposing, as very many have done, that its operations are in all cases promoted by a large public expenditure. To a certain extent this is indeed true. A moderate increase of taxation has the same effects on the habits and industry of a nation that an increase of his family, or of his necessary and unavoidable expenses, has upon a private individual. Man is not influenced solely by hope, — he is also powerfully operated upon by fear; taxation brings the latter principle into the field. To the desire of rising in the world inherent in the breast of every individual, an increase of taxation superadds the fear of being cast down to a lower station, — of being deprived of conveniences and gratifications which habit has rendered almost indispensable; and the combined influence of the two principles produces efforts that could not be produced by the unassisted agency of either. They stimulate individuals to endeavour, by increased efforts of industry and economy, to repair the breach taxation has made in their fortunes; and it not unfrequently happens that their efforts do more than this, and that, consequently, the national wealth is increased through the increase of taxation. But we must be on our guard against the abuse of this doctrine. To render an increase of taxation a cause of greater exertion, economy, and invention, its increase should be slow and gradual; and it should never be carried to such a height as to incapacitate individuals from meeting the sacrifices it imposes on them by such a moderate degree of increased exertion and economy as it may be in their

power to make, without requiring any very violent change in their habits. The increase of taxation must not be such as to render it impracticable to overcome its influence, or to induce the belief that it is impracticable. Difficulties that seem to be surmountable sharpen the inventive powers, and are readily grappled with; but an apparently insurmountable difficulty, or such an excessive weight of taxation as it was deemed impossible to meet, would not stimulate, but destroy exertion. Instead of producing new efforts of ingenuity and economy, it would produce only despair. Whenever taxation becomes so heavy that the produce it takes from individuals can no longer be replaced by fresh efforts, these efforts uniformly cease to be made; the population becomes dispirited, industry is paralysed, and the country rapidly declines.

Ambition to rise is the animating principle of society. Instead of remaining satisfied with the condition of their fathers, the great object of mankind in every age has been to rise above it,— to elevate themselves in the scale of wealth; to continue stationary, or to retrograde, is not natural to society. Man from youth grows to manhood, then decays and dies; but such is not the destiny of nations. The arts, sciences, and capital of one generation become the patrimony of that which succeeds them, and in their hands are augmented and rendered more efficient; so that, if not counteracted by the want of security, or by other adventitious causes, the principle of improvement would always operate, and would secure the constant advancement of nations in wealth and population.

Such is a short outline of the circumstances on which the production of wealth depends. It is difficult in separately considering the influence of the combination and division of employments, and of the introduction and improvement of machinery, to avoid ascribing an undue degree of importance to the one immediately under consideration. But neither is intitled to any pre-eminence over the other. They are alike important; or rather, we should say, they are alike indispensable to the production of wealth. It would, indeed, be quite as profitable to inquire whether the heart or the lungs be most essential to animal existence, as it is to inquire whether the division and combination of employments, or the command of capital, including tools and machines, be most essential to the growth of opulence and civilization. Without their combined and powerful aid, man must have continued sunk in primeval barbarism and ignorance. Take away the division and combination of employments, and the isolated efforts of individuals will be wholly unable to produce any considerable result; and take away capital, or the aid derived from previous savings, and from tools and machinery, and we shall immediately sink to the level of the Australian savages.

It would be inconsistent with the objects and limits of this work to enter further into details. The sketch now given comprises, we believe, an accurate statement of the great principles that lie at the bottom of the science, and by the application of which a correct judgment may be formed of most practical measures affecting the production of wealth. But those who wish for more detailed statements, and expositions of difficulties, must resort to works especially appropriated to such investigations.

The second great division of Political Economy has for its object to inquire into the laws which regulate the distribution of wealth among the various ranks and orders of the community.

II. Distribution of Wealth.

The inhabitants of such countries as have made any considerable progress in civilization may be divided into the three great classes of labourers, landlords, and capitalists; that is, into those who employ themselves for hire in any undertaking, those to whom the lands belong, and those who are the owners of capital. An individual may combine in his own person each of these separate characters; but they are, notwithstanding, sufficiently well marked to admit of their classification and separate consideration in the case of all individuals. And whatever be the condition of any country or society, whether it be rude or refined, rich or poor, every person belonging to it, who is not a pauper, or who does not subsist on the bounty of others, may be reckoned in one or other of these classes. They divide amongst them all the wealth of the community. Public functionaries of all sorts, and the various individuals engaged in what are called liberal or learned professions, exchange their services for valuable considerations. The whole subsistence of such persons, in so far as they depend upon their employments, is derived from wages; and they are as evidently labourers as if they handled a spade or a plough. "Every man," says Dr. Paley, "has his work. The kind of work varies, and that is all the difference there is. A great deal of labour exists besides that of the hands: many species of industry beside bodily operation; equally necessary, requiring equal assiduity, more attention, more anxiety. It is not true, therefore, that men of elevated stations are exempted from work; it is only true that there is assigned to them work of a different kind: whether more easy or more pleasant may be questioned; but certainly not less wanted, nor less essential to the common good." (*Assize Sermon*, 29th July, 1795.) Hence it is that the inquiry into the distribution of wealth among the different orders of the society, resolves itself into an investigation of the laws which regulate wages, rent, and profit, and of the best methods of providing for the exigencies of the poor, or of those who are unable to provide for themselves. We believe, however, that it will be the preferable plan to refer the consideration of these topics to the heads now mentioned, which will, consequently, comprise all that is essential to a general view of this department of the science.

Among the many works that have been written on this science, the first place is due to the *Wealth of Nations*, by Adam Smith: an edition of this work was published in 1838 in one volume, 8vo., with notes and illustrations by the author of this article. See also Ricardo's *Principles of Political Economy and Taxation; Torrens on the Production of Wealth;* Senior's art. on Political Economy in the *Encyclopædia Metropolitana;* M'Culloch's *Principles of Political Economy;* Say, *Traité d'Economie Politique*, &c.

POʹLITICS (Gr. πολις, *a city*), may be considered either as a science or an art, according to the manner in which it is treated. Political science is that which treats of the theory and practice of government, and the subjects which it comprises have been arranged under the following heads: — 1. Natural law; 2. Abstract politics, *i.e.* the object of a state, and the relations between it and individual citizens; 3. Political economy; 4. The science of police, or municipal regulation; 5. Practical politics, or the conduct of the immediate public affairs of a state; 6. History of politics; 7. History of the European system of states, being the only system in which the modern art of politics has received a practical development; 8. Statistics; 9. Positive law relating to state affairs, commonly called constitutional law; 10. Practical law of nations; 11. Diplomacy; 12. The technical science of politics, an acquaintance with the forms and style of public business in different countries. The ancient Greek writers treated the science of politics uniformly with reference to an imaginary perfect state; the constitution of which each propounded according to his own speculative views, and then proceeded to show in what respects existing governments differed from this ideal standard, the cause of these variations, &c.

POLL. In Politics. *See* Parliament.

POLLARD. A tree with the head cut off at the height of 10 or 12 feet from the ground, for the purpose of inducing it to throw out branches all round the section where amputation has taken place; which branches are cut off periodically, when they attain the length of 8 or 10 feet, to be used as fuel, fence wood, or for other rustic purposes. Pollard trees are for the most part found in hedgerows, which they greatly injure by the dense shade produced by their branches on the plants below; and excepting when the round formal heads of the pollards enter into combination with overgrown hedge plants, or with large trees which have not been pollarded, they disfigure the landscape, from the sameness of their appearance, and their expression of meanness, as compared with that of trees undecapitated and left in all their native luxuriance. In the time of Evelyn the term pollard appears to have been chiefly applied to trees which were lopped or deprived of their side branches, excepting a few at top, leaving the tree standing like a naked pole. Examples of this kind of pollard are frequent among the hedgerow elms in the neighbourhood of London. The decapitated tree, now called a pollard, was in Evelyn's time called a dottard.

POLLEN. In Botany, the pulverulent substance which fills the cells of the anthers of a plant, consisting of a multitude of little hollow cases filled with a fluid holding very minute molecular matter in suspension. The latter is eventually discharged by the grains of pollen through their hollow tubes, and is supposed to be the spermatic fluid of a plant.

POLLEN TUBES, are the tubular processes emitted by the pollen when it comes in contact with the stigma of a plant, and which are supposed to conduct the impregnating matter down the style into the ovules through the foramen.

POLL TAX. A tax still levied in many of the Continental states, and formerly also in England, in proportion to the rank or fortune of the individual. In England this species of tax was first levied in 1378; and, as is well known, it was from the brutality with which the levying of it was accompanied that the rebellion of Wat Tyler took its rise in 1381. Various poll taxes were levied at different periods in the subsequent history of England; but they were finally abolished in the reign of William III. *See* Taxation.

POʹLLUX. In Astronomy, one of the twins forming the constellation *Gemini*. (*See* Castor.) Pollux is also

the name of a star of the second magnitude in the same constellation.

PO'LYARCHY. (Gr. πολυς, *many*, and ἀρχειν, *to govern.*) A word sometimes used by political writers in a sense opposed to monarchy: the government of many, whether a privileged class (aristocracy), or the people at large (democracy).

POLYCHRO'ITE. (Gr. πολυς, and χροα, *colour.*) A term applied to the colouring matter of saffron, in consequence of the variety of colours which it exhibits when acted upon by various re-agents.

PO'LYCHREST. (Gr. πολυς, and χρηστος, *useful.*) A term applied by the old chemists to certain preparations which they regarded as possessed of multifarious virtues. *Polychrest salt* was the sulphate of potash.

POLYGALA'CEÆ. (Polygala, one of the genera.) A natural order of irregular Polypetalous Exogens, possessing tonic, astringent, and nephritic properties. The species are also sometimes cultivated for the sake of their beautiful flowers; they usually inhabit temperate climates, and are particularly common at the Cape of Good Hope. Rhatany root, a powerful astringent, belongs to *Krameria*, a genus of this order.

POLY'GAMOUS (Gr. πολυς, and γαμος, *marriage*), in Grasses, signifies when one of the two flowerets of which a spikelet consists is unisexual, the other hermaphrodite, as in *Spodiopogon*, &c.; in other plants it expresses the presence in the same individual of male, female, and hermaphrodite flowers.

POLY'GAMY. (Gr. πολυς, and γαμος, *marriage.*) The custom of having several wives; a custom apparently common to all nations in remote antiquity, and common now to most of those in which the tie of marriage is recognized, and to which Christianity has not extended. It was admitted among the Patriarchs, and under the Mosaic dispensation (Exod. xxi. 10., Deut. xxi. 15.); and Selden (*Uxor Hebraica*) has shown its prevalence among the Jews, without mentioning the extraordinary instances of sovereigns, such as David and Solomon, recounted in Scripture. It may be questioned, however, whether it continued at the period of our Saviour's preaching. Certainly his injunctions in regard to marriage seem rather to be founded on the supposition of monogamy; and the absence of positive injunctions against polygamy has been relied on by some modern disputants, with very little reason, as an authority that the licence assumed by the holy men of the Old Testament is not revoked. The severer manners of Western nations seem to have repudiated it. It was no part of Grecian manners: the notion that the Athenian laws allowed of two wives (founded in part on a passage in *Athenæus*, l. xiii. ch. 1.) seems a mistake; but it appears to have been allowed to a citizen, in addition to his lawful wife, herself a citizen, to live in a kind of legitimate concubinage with a female not belonging to that class. Thus (if there is any truth in the story of Socrates' two wives) his plague, Xantippe, was the wife by night, while the softer Myrto was only a wife by courtesy. In republican Rome no such licence was known; but under the emperors the practice of polygamy seems to have crept in, though repudiated both by the moral sense and civil usages of the people. Valentinian I. legalized it by an edict. But the Christian ecclesiastics of the empire strenuously opposed it; and it disappeared altogether, we believe, from Christendom with the fall of the Roman empire. In the East it has continued to prevail.

A few bold writers in modern times have raised the defence of polygamy, grounded on the supposed absence of its express prohibition. Bernardus Achinus, a well-known and able but unsteady theologian of the 16th century, who belonged by turns to the Roman Catholic and Protestant communions, is among the most remarkable. Lyserus (*Polygamia Triumphatrix*) adopted a still more decided view. The Rev. Mr. Madon, in his *Thelyphthora* (a work which excited an extraordinary and very unfavourable sensation on its appearance), limited the privilege of polygamy to men; and asserted that the injunction of St. Paul, that a bishop "should be the husband of one wife," plainly demonstrated its lawfulness in others; meaning one wife at a time: a supposition which is not improbable, although it will scarcely support his conclusions. But a greater number of philosophical writers have sought for a justification of the practice in the East. Voltaire, Montesquieu, and others, defend it on the ground of the rapid decay of female beauty in those regions. Montesquieu also relies on the strange notion, that the number of females in eastern countries is much greater than that of males; which the traveller Bruce asserts on the authority of his own observations. But the supposed fact on which these reasonings rest seems to be altogether imaginary. At all events, the *practice* of polygamy in the East is confined to so few that it can have little direct effect on manners, and none on population. Mr. Urquhart, who endeavours to place Turkish usages in a favourable contrast with those of the West, after to a certain extent defending polygamy, says rather inconsistently, "While the law of nature renders this practice an impossibility as regards the community, it is here still farther restrained, among the few who have the means of indulging in it, both by the domestic unquiet that results from it, and by the public censure and reprobation of which it is the object." (*Spirit of the East.*) He adds, that in his time "a case of polygamy was unknown in Candia, among a population of 40,000 Mussulmen." And Niebuhr says, that in Arabia the conduct of those who take more than one wife "is blamed by all other men." But it seems scarcely to have occurred to most reasoners that while polygamy itself is rare, its recognition is almost always accompanied with the toleration of concubinage by public morality. The man who is not rich enough to take two wives, or who does not choose to encounter the household disturbances which follow such an arrangement, falls entirely in with the public opinion of his class, in taking into his family a recognized concubine to dwell with his lawful spouse. Our Western manners divide the female part of the community into two classes: a greater number, treated with the highest respect, and in whom perfect purity is presumed; a smaller number, abandoned to utter degradation. Where polygamy and concubinage are recognized, there is probably much less gross prostitution; but the general character of the sex stands on a lower basis.

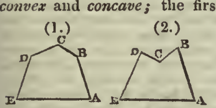
POLYGA'STRIA. (Gr. πολυς, and γαστηρ, *a stomach.*) The name of the most minute and simple class of Infusories, and of the whole animal kingdom. The Polygastrians are characterized by Ehrenberg as animalcules devoid of spinal marrow, and of vascular and respiratory organs, with many stomachs, of an indefinite form, and androgynous, with spurious locomotive organs of various nature. They are all endowed with an organization characteristic of the animal kingdom; and manifest such modifications of internal structure and external form that they can be divided into twenty-two families, of which eleven are naked and eleven clothed in a siliceous case. Forty-eight species, referable to twenty-one distinct genera, are provided with eyes or coloured eye-specks; and, among these, nervous ganglia have been detected beneath the eye in *Amblyophis* and *Euglena*. They occur in all parts of the world, and differ according to diversity of climate, region, kind of water, &c. They are invisible to the naked eye; but, by their immense numbers, can impart a distinct colour to the water in which they swarm: they are one of the causes of the phosphorescence of the sea. They enjoy the most extensive powers of reproduction; and through their faculty of spontaneous *fission*, the individual becomes constant, and, as it were, perpetually renews its youth. By virtue of the imperishability of their external cases the *Polygastria* have formed vast masses of rock, as at Bilin in Bohemia, where a single stratum, extending over a wide area, is no less than 14 feet thick; and this consists exclusively of the cases of *Bacillaria*, *Gaillonella*, &c., united together without any visible cement. They sometimes so choke up water by their vast numbers as to cause the death of fishes contained therein. They appear never to sleep: they are very tenacious of life, and fall into a kind of torpidity by excess of dryness, heat, or cold. The more minute species are probably often suspended in the air. They act according to external circumstances, as the higher organized animals do. They are injuriously affected or killed by strong poisons; but can sometimes support great degrees of warmth and cold, and can live with or without light: their motions are slow. Ehrenberg calculates that the *Monas punctum*, if it were to continue its ordinary rate of motion in a straight line, would traverse one mile of space in five years; while the *Navicula grandis* would require forty years to travel over the same distance. But their movements manifest the phenomena of consciousness and choice, and their muscular power is indicated by the strong maxillary apparatus with which many are provided.

PO'LYGLOT. (Gr. πολυς, and γλωττα, *language.*) A word generally applied to such Bibles as have been printed with the text represented in various languages. The most ancient instance of this parallel representation of various texts is the work of Origen, known by the name of the *Hexapla*, in imitation of which several similar editions of the Scriptures have been published since the invention of printing; of which the most important are, — 1. *The Complutensian*, or edition of Cardinal Ximenes, printed at Alcala in Spain, 1515, in four languages, comprehended in six vols. folio. 2. *The Plantin*, Antwerp, 1572. 3. *The Polyglot* of De Sacy, Paris, 1645. 4. *The English*, or *Walton's Polyglot*, London, 1657. These contain among them the Hebrew, Chaldee, Syriac, and Samaritan texts, with Latin versions of each; the Septuagint, the Greek of the New Testament, the Italic and the Vulgate; with some of the Hebrew and Chaldee paraphrases, and copious indexes and grammatical illustrations. 5. *Hutter's Polyglot*, Nuremberg, 1599, contains twelve languages; the Hebrew, Syriac, Greek, Latin, German, Bohemian, Italian, Spanish, French, English, Danish, and Polish.

PO'LYGON (Gr. πολυς, and γωνια, *angle*), according to Euclid, is any plane rectilinear figure having more than four sides or four angles; but, in treating of polygons generally, geometers also include the triangle and the quadrangle. If the sides of the polygon are all equal, it is said to be a regular polygon; otherwise it is irregular. Every regular polygon can be circumscribed by a circle, or have a circle inscribed in it; but of irregular polygons, excepting triangles, there is only one case in which a circle will pass through all their angular points; namely, when the polygon has an equal number of sides, one half of which are equal to one another, and the other half also equal to one another, but different from the former, and the equal and unequal sides are placed alternately. It is obvious that all the angles of such a figure are equal.

Euclid has shown in the *Elements* how to inscribe a triangle, a square, and a pentagon in a given circle; and as any arc of a circle may be bisected geometrically, and the halves again bisected continually, it follows that any regular polygon, of which the number of sides is 2^n (n being any number whatever), or 3×2^n, or 5×2^n, may be inscribed in a circle by elementary geometry. Until a recent discovery respecting the division of angles was made by Gauss, it was supposed that if the number of sides of a polygon was any other prime number than 3 or 5, the figure could not be inscribed in a circle; but this geometer, in his *Disquisitiones Arithmeticæ*, has demonstrated that every polygon, the number of whose sides is a prime number of the form $2^n + 1$, may be geometrically inscribed in a circle. When $n = 1$, this form gives 3, or the triangle; when $n = 2$, it gives 5, or the pentagon; when $n = 3$, it gives 9, which is not a prime; when $n = 4$, it gives 17, whence a seventeen-sided figure may be inscribed in a circle geometrically. The next prime is found by making $n = 8$, when the form gives 257.

In order to investigate the general properties of polygons, it is necessary to divide them into two classes, *convex* and *concave;* the first comprehending those of which all the interior angles are less than two right angles (fig. 1.), and the second those which have one or more *re-entering* angles, as C (fig. 2.). If we call those the *interior* angles of the polygon which belong to the interior of the figure (whether less or greater than two right angles), and those *exterior* angles which are obtained by substracting each interior angle from four right angles, the two following theorems will be true of the polygons of both classes: —



1. The sum of the interior angles of a polygon is equal to as many times two right angles as there are sides *minus* two. Thus, let S denote the sum of the interior angles, R a right angle, and n the number of sides of the polygon; then $S = 2(n - 2) R$.

2. The sum of the exterior angles of a polygon is equal to as many times two right angles as there are sides *plus* two. Let S′ be the sum of the exterior angles, as above defined; then $S' = 2(n + 2) R$.

Any polygon may be decomposed into triangles by drawing straight lines from one of its angular points to each of the opposite angles, and the area of the polygon is the sum of the areas of all the component triangles. But a beautiful theorem was found by L'Huilier of Geneva, by means of which, when the sides and angles of a polygon are known, the area is found without decomposing it into triangles, which, when the number of sides is considerable, leads to laborious calculations. The theorem is this:—The double of the surface of any rectilinear figure is equal to the sum of the rectangles of its sides, taken two and two, *excepting one*, multiplied by the sine of the sum of the supplements of the interior angles contained between each pair of sides. Thus, in the preceding figure (fig. 1.), let A, B, C, D, E be the supplements of the interior angles at those points; then

$$\begin{aligned}2\text{ area} = {} & AB \times BC \sin. B \\ & + AB \times CD \sin. (B + C) \\ & + AB \times DE \sin. (B + C + D) \\ & + BC \times CD \sin. C \\ & + BC \times DE \sin. (C + D) \\ & + CD \times DE \sin. D.\end{aligned}$$

This formula also gives the area of the polygons of the second class (fig. 2.); only the supplement of the re-entering angle C must be taken with the negative sign. (See *L'Huilier's Polygonométrie*, Genève, 1789.)

Polygon, in Fortification, is either *exterior* or *interior*. The exterior polygon is the figure formed by lines connecting the angles of the bastions with one another all round the work; the interior polygon by lines connecting the centres of the bastions all round.

POLYGONA'CEÆ. (Polygonum, one of the genera.) A natural order of herbaceous, rarely shrubby, apetalous Exogens, inhabiting the whole world; distinguished from most other plants by the cohesion of the scarious stipules into a sheath, technically called an *ochrea* or *boot*, and by their triangular fruit. Sorrel on the one hand, and rhubarb on the other, represent the general qualities of this order. While the leaves and young shoots are acid and agreeable, the roots are universally nauseous and purgative. *Rumex acetosa* contains pure oxalic acid, and many species of Polygonum are used in dyeing. The *Rheum* or rhubarb, and *Rumex* or dock, are well-known plants of this order; which is also sometimes remarkably astringent, as in the case of the *Coccoloba uvifera*, or sea-side grape of the West Indies, an extract of whose bark forms a kind of kino.

POLYGONAL NUMBERS, in Arithmetic, are the successive sums of a series of numbers in arithmetical progression. When the common difference of the series in arithmetical progression is 1, then the sums of the terms give the *triangular* numbers; when the common difference of the terms of the arithmetical series is 2, the sums of the terms are the *square* numbers; when the difference is 3, the sums are the *pentagonal* numbers; and so on. Thus: —

Common difference = 1;	1, 2, 3, 4, 5, 6, &c.
Triangular numbers	1, 3, 6, 10, 15, 21, &c.
Common difference = 2;	1, 3, 5, 7, 9, 11, &c.
Square numbers	1, 4, 9, 16, 25, 36, &c.
Common difference = 3;	1, 4, 7, 10, 13, 16, &c.
Pentagonal numbers	1, 5, 12, 22, 35, 51, &c.

and so on. These numbers are called, in general, *polygonal*, from possessing this property, that the same number of points may be arranged in the form of that polygonal figure to which it belongs. For example, the pentagonal numbers 5, 12, 22, 35, 51, &c. may be severally arranged in a pentagonal form. Thus, in the annexed figure, 5 points form the pentagon *a b c d e;* 12 the pentagon *a f g h i*, with the former enclosed; 22 the pentagon *a k l m n*, with the two former enclosed.

A very general and remarkable property of polygonal numbers was discovered by Fermat, though it has yet been demonstrated only in respect of the triangular and square numbers. It is this:—Every number whatever is the sum of one, two, or three triangular numbers; the sum of one, two, three, or four squares; the sum of one, two, three, four, or five pentagonal numbers; and so on. *See* Figurate Numbers.

POLYGON OF FORCES. In Mechanics, the name given to a theorem, the discovery of which is attributed to Leibnitz. The theorem is this: — If any number of forces act upon a point, and a polygon be taken, one of the sides of which is formed by the line representing one of the forces, and the following sides in succession by lines representing the other forces in magnitude, and parallel to their directions, then the line which completes the polygon will represent the resultant of all the forces.

PO'LYGONO'METRY. The doctrine of polygons, as trigonometry is the doctrine of triangles. The properties of polygons are usually investigated by resolving them into triangles; their areas, however, may be found, when so many of their sides and angles as suffice to determine them are known. *See* Polygon.

PO'LYGRAM. (Gr. πολυς, *many*, and γϱαμμα, *a line*.) A figure consisting of many lines.

PO'LYGRAPH. (Gr. πολυς, and γϱάφω, *I write*.) In Bibliography, a name invented to designate a collection of different works either by one or several authors.

POLY'HALITE. (Gr. πολυς, and ἁλς, *salt*.) A mineral found at Ischel, in Upper Austria, composed of muriate of soda, and of the sulphates of magnesia, lime, and potash.

POLYHE'DRON. (Gr. πολυς, and ἑδϱα, *seat*.) In Geometry, a solid body bounded by many faces or planes. When all the faces are regular polygons, similar and equal to each other, the solid becomes a regular body. It may be demonstrated that only five regular solids can exist; namely, the tetraedron, the hexaedron, the octaedron, the dodecaedron, and the icosaedron. See the terms; see also Platonic Bodies.

Polyhedron. In Optics. *See* Polyscope.

POLYHY'MNIA, the muse who presided over lyric poetry: —

> Nec Polyhymnia
> Lesboam refugit tendere barbiton. *Hom. Od.* i. 1.

PO'LYMI'GNITE. (Gr. πολυς, and μιγνυμι, *I mix*.) A mineral which occurs in small prismatic crystals of a metallic lustre; its constituents are titanic acid, zirconia, lime, yttria, oxides of iron, cerium and manganese, magnesia, potassa, silica, and oxide of tin. It is found in Norway.

POLYNO'MIAL, or MULTINOMIAL, in Algebra, denotes a quantity having many terms. Such, for example, is the expression $a + 2b + 3c + nd$, &c.

POLYO'PTRON. (Gr. πολυς, and οπτϱον, *a looking-glass*.) In Optics, a glass through which objects appear multiplied, but diminished. It consists of a lens one side of which is plane, but in the other are ground several spherical concavities. Each of these concavities

becomes a plano-concave lens, through which an object appears diminished; and when there are a number of them together, the object will be seen through each, and thus multiplied.

PO'LYPES, *Polypi.* (Gr. πολυς, and πους, *a foot.*) The name of an extensive group of radiated animals in the system of Cuvier, associated together by the common character of a fleshy body, of a conical or cylindrical form, commonly fixed by one extremity, and with the mouth situated at the opposite end and surrounded by more or less numerous arms or tentacles. Under this external form is masked various grades of organization, of which three at least have been well defined by recent and minute anatomical researches.

The lowest grade of organization is manifested by the fresh-water polype (*Hydra*), and the compound marine corallines (*Sertulariæ, Tubulariæ*, &c.). The body here consists of a granular parenchyma, having a contractile power in every part, not requiring a distinct allocation and arrangement of muscular fibres. When it is defended, as in the Corallines, by a polypary, it can be retracted into its cell without being folded upon itself. The oral tentacles are not provided with vibratile cilia; the stomach is not distinct from the parietes of the body. The polypes thus organized have been termed *Dimorpheæ* by Ehrenberg; and *Nudibrachiata*, or Hydriform Polypes, by Dr. Farre. In the second group of Polypes the body is distinctly membranous and fibrous, and the stomach forms a separate pouch suspended in its centre. The stomach has but one external orifice, which serves for mouth and vent; but posteriorly it communicates with the main cavity of the body. This is divided into several compartments by vertical partitions passing from the walls of the cavity to those of the stomach; and with the chambers thus formed the tubular arms surrounding the mouth communicate: these arms are not ciliated externally. This group of Polypes has been termed *Anthozoa* by Ehrenberg: it includes the Sea-anemonies, Madrepores, Coral-polypes, &c. In the third and highest group of Polypes the parietes of the stomach are not only distinct from those of the body, but are continued into an intestinal tube, which is reflected forward, and terminates in a distinct anal aperture near the mouth: the tentacula are provided with vibratile cilia. The Polypes of this division are aggregated or compound, and provided with flexible or calcareous cells: they have been termed *Bryozoa* by Ehrenberg, and *Ciliobrachiata* by Dr. Farre. All the groups of Polypes propagate by gemmation, and likewise by ova, which are first developed into ciliated and locomotive gemmules. In the *Ciliobrachiata* the sexes are distinct.

POLYPHEMUS. *See* CYCLOPS.

PO'LYPUS. In Surgery, a fleshy tumour, which is occasionally formed in the nostrils: the same term is also applied to a fleshy tumour of the uterus.

POLYSA'RCIA. (Gr. πολυς, and σαρξ, *flesh.*) Corpulency.

PO'LYSCOPE. (Gr. πολυς, and σκοπεω, *I view.*) In Optics, a lens plane on one side and convex on the other; but of which the convex side is formed of several plane surfaces, or *facettes*, so that an object seen through it appears multiplied. The reason of the multiplication of the image is this: — When the opposite sides of a thick piece of glass are not parallel, an object seen through it appears out of its true place on account of the refraction; consequently, if a lens is ground so that portions of its convex surface are differently inclined to its plane side, the object will appear in different places at the same time. The polyscope may be used to collect the images of several dispersed objects into a single point, or to collect parts of the same object represented in different places, so as to form a single image. The instrument is a mere toy, and only used for the purpose of amusement.

POLYSPA'STON. A term used by some of the old writers on mechanics to denote an assemblage of pulleys for raising heavy weights.

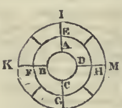
PO'LYSTYLE. (Gr. πολυς, and στυλος, *a column.*) In Architecture, an edifice in which there are a great number of columns.

POLYTE'CHNIC SCHOOL. (Gr. πολυς, and τεχνη, *art.*) This establishment was founded in 1794, at Paris, by a decree of the National Convention. Its object is to instruct youth in the mathematical, physical, and chemical sciences. Napoleon, who introduced various modifications into its constitution, gave a military turn to its discipline. It prepares pupils for the artillery service and civil and military engineering. The number is limited to 300. Youths are admitted between the age of sixteen and twenty, and the course of study lasts two years. In the lists of its professors have been included the illustrious names of Lagrange, La Place, Monge, Berthollet, &c.; and from the ranks of its pupils have proceeded, almost without exception, all the mathematicians and philosophers of France who have attained to eminence during the last half century.

POLYTHALAMA'CEANS, *Polythalamacea.* (Gr. πολυς, *many*, and θαλαμος, *a chamber.*) A name applied by De Blainville to an order of Cephalopods, including those which have many-chambered shells. Like all divisions founded merely on external or dermal characters, it contains animals of different degrees of organization, and which cannot be grouped together in the same order in a natural system. *See* TETRABRANCHIATES.

POLY'THEISM. (Gr. πολυς, and Θεος, *God.*) The doctrine of a plurality of gods. Sabianism (or planet-worship), Zendism, dæmon worship, hero-worship, and animal worship, together with the *fetichism* of some Negro tribes, may all be considered as varieties of Polytheism. That the first deviation from pure Theism, such as we believe to have been at the outset revealed to man, was into the worship of the sun, moon, and stars (the host of heaven; Hebr. Tsaba, *an host;* whence Tsabianism or Sabianism, which see), is sufficiently probable. The origin of the worship of the good and evil principle as distinct deities, which characterized the religion of some oriental nations, is not so easily explicable. Some have attributed it to the recognition of the opposites to those phenomena which had been deified in the Sabian notions, — *e. g.* darkness as contrary to light, night to day, &c.; some to traditionary belief in the existence of evil or reprobate spirits; some to a mere philosophical theory adapted by priests to popular comprehension. Dæmon worship, or the worship of intermediate intelligences, appropriated to external objects, and subordinate to the highest God, was a natural effect of Sabianism. The worship of heroes, or deified mortals, arose again from it in a later stage of society; and the most probable theory of the greatest systems of Polytheism which have been recognized by divisions of the human race, viz. the Egyptian, Greek, Indian, and Scandinavian, seems to be this, that hero worship, the most congenial of all to the vulgar imagination, superseded former modes of belief; that the gods were actually heroes, who had gradually absorbed to themselves the honours formerly paid to dæmons or intelligences, and to the host of heaven, so that their attributes, in later mythology, present a vague mixture of the characters of all. If, however, this be the case, it remains to be explained how, *after* the gods of Olympus had acquired their station and attributes in the Grecian religion, a secondary race of heroes, the ηρωες, properly so called (whose worship is quite of recent origin, and certainly posterior to Homer), should have found a place in the same mythology. The strange system of animal worship seems peculiar to ancient Egypt, and has been derived by some from the natural circumstances of the country; the scarcity of domesticated animals having given them an importance which the priests made use of, and connected with superstition. As to the theory and general history of polytheism, the following among many other books may be mentioned: — *Stillingfleet's Origines Sacræ; Kames's Sketches of the History of Man; Court de Gebelin Monde Primitif; Bryant's Mythology;* the Works of Herder; *Warburton's Divine Legation; Cudworth's Intellectual System; Vossius, De Origine Idololatriæ; Mem. de l'Acad. des Inscr.* vol. xxxviii.

POLYZO'NAL LENS. (Gr. πολυς, and ζωνη, *zone.*) The name given by Sir David Brewster to a burning lens constructed of several zones or rings, each of which may be again composed of separate segments. In the annexed figure, A B C D is a central lens formed of one piece of glass; E F G H is a middle ring, or zone, composed of four separate pieces; I K L M is another ring composed of eight segments, and surrounding the former. The number of zones, and of parts in each, may be as great or as small as we please.



This method of forming lenses is attended with several important advantages. The difficulty of procuring flint glass of sufficient purity to render it fit for the construction of a solid lens of large dimensions is removed, and the expense greatly diminished. If impurity exist in any of the spherical segments, or if an accident happen to any of them, it can easily be replaced. Another advantage attending the construction is, that it enables us to correct, very nearly, the spherical aberration, by making the foci of each zone coincide. Lenses of this kind have been made in France of crown glass, and have been introduced into the principal French light-houses. One was constructed, under the directions of Sir David Brewster, for the commissioners of the northern light-houses. It was made of pure flint glass, was three feet in diameter, and consisted of numerous zones and segments. (See *Brewster's Treatise on New Philosophical Instruments;* and "Optics" in *Lardner's Cyclopædia.*)

POLY'ZOONS. *Polyzoa.* (Gr. πολυς, and ζωον, *animal.*) A class of compound animals resembling in their organs of support the Sertularians, but in their internal organization approaching nearly to the compound Ascidians.

POMA'CEÆ. (Lat. pomum, *an apple.*) That division of the natural order *Rosaceæ* to which the apple, pear,

quince, and medlar belong. It differs from *Rosaceæ* proper in having an inferior ovary.

POMEGRA'NATE. The fruit of the *Punica granatum*. The pulp is acid, and the rind highly astringent. The dried flowers, which are also astringent, were formerly used in medicine, under the name of Balaustine flowers.

POMŒ'RIUM. (Lat. post, *behind*, and murus, *a wall*.) In Roman Antiquities, a space of ground, both within and without the walls of a city, kept free from buildings (*Livy*, xiii.), and consecrated by a reliigous ceremony derived from the Etruscans. (See a memoir of D'Anville on the extent of ancient Rome, *Mem. de l'Acad. des Inscr*. vol. xxi. p. 206.) When it was found necessary to extend the limits of any city, a new *pomœcium* was formed, and the former one desecrated.

POMO'NA. The Italian goddess of fruit trees. Her worship was assiduously cultivated at Rome, where there was a *flamen pomonalis*, who sacrificed to her every year for the preservation of the fruit. The story of Pomona and Vertumnus is well known. (See *Ovid. Met*. 14. 623.) The name is derived from poma, *fruit*.

PO'MPHOLIX. (Gr. πομφος, *a bubble*.) An alchemical term for oxide of zinc.

Po'mpholix. In Medicine, a vesicular eruption upon the skin.

PO'MUM ADA'MI. *Adam's apple*. The protuberance in front of the neck formed by the thyroid gland. It has been fancifully supposed to represent the forbidden apple eaten by Adam.

POND. An artificial excavation in the soil, or a natural hollow dammed up for the purpose of detaining water, generally made in fields in order to supply drink to pasturing animals. The essential difference between a pond and a lake is, that the former is formed by art, the water being often ponded, or impounded, by a bank of earth thrown across a natural gutter, hollow, or bourne containing a stream. In Gloucestershire, Kent, and other counties where the soil does not abound in springs, the formation of ponds in the fields is as essential to the business of farming as the building of farm offices. A pond in a garden, when of a round form, is termed a basin; and when of some length, with parallel sides, a canal.

PO'NE. (Lat.) In Law, a writ which lies to remove actions of debt, detinue, writs of right, nuisances, &c., out of the county or other inferior court into the Common Pleas, and sometimes into the Queen's Bench.

PONS VARO'LII. The bridge of Varolius. An arched eminence of the *medulla oblongata*, formed by the two exterior crura of the cerebellum becoming flattened, and passing over the crura of the cerebrum.

PO'NTEE. In Glass Manufacture, an iron instrument by which the hot glass is taken out of the glass-pot.

PO'NTIA. (Gr. Ποντια, one of the names of the goddess of love.) A genus of butterflies, of which the common white or cabbage butterfly (*Pontia brassicæ*) is a well-known native species.

PO'NTIFEX. (Lat.) The highest Roman sacerdotal title. Numa instituted four pontifices, chosen from the patricians; to which were added, long subsequently, four plebeians. Sylla increased their number to fifteen. The college was divided into two classes, distinguished by the epithets *majores* and *minores*; but it is not certain whether this difference of title marked out the patricians from the plebeians, or the more ancient members from the seven added by Sylla. The pontifices judged in all causes relating to sacred things, and inspected the conduct of the inferior priests. They were a self-elected body down to the latter ages of the republic, when the power of election was sometimes held by the people. It was finally vested in the emperors, who added as many to their numbers as they thought fit. The chief of the pontifices was called the *pontifex maximus*, and was always created by the people, being generally chosen from those who had borne the first offices in the state. His station was one of great dignity and power, as he not only had supreme authority in religious matters, but, in consequence of the close connection between the civil government and religion of Rome, he had also considerable political influence. The title of pontifex maximus being for life, Augustus never assumed it till the death of Lepidus, after which it was always held by himself and his successors to the time of Theodosius. The insignia consisted of the *toga prætexta*, and a conical woollen cap with a tassel (*galerus*). (See the *Mem. de l'Ac. des Inscr*., vols. xii. xv. xxiv. xxxvii.) From this word the well-known title of Pontiff in modern Europe is derived. "Supreme Pontiff" is a common style of the pope.

PONTOO'N. A Military term, denoting a kind of flat-bottomed boat, generally lined within and without with tin. Our pontoons are about 21 feet long, 5 feet broad, and 2 feet deep. They are carried along with an army for the purpose of making temporary bridges, called *pontoon bridges*, by which an army is pursued over rivers.

POOP. A partial deck extending close aft, above the complete deck of the vessel. A sea coming over the stern is said to *poop* the vessel.

POOR, THE. (Lat. pauperes.) In Political Economy, the term employed to designate those persons, or that portion of the population of any county, who, being destitute of wealth, are, through age, bodily or mental infirmity, want of employment, or other cause, unable to support themselves, and have to depend for support on the contributions of others.

The first notice of the poor by the legislature of England appears to have occurred in 1376; and there does not seem to be any good grounds for thinking that any portion of the people were known by this designation previously to the 14th century. The truth is, how paradoxical soever the statement may at first appear, that the poor, as a class, owe their existence to the abolition of villenage and the progress of civilization. Previously to this abolition, the great bulk of the people were in a state of predial slavery, or in a condition closely resembling that of the Spartan helots. But in such a state of society the class of persons now known as the destitute poor could not exist. It is essential to the idea of slavery, whether predial or absolute, that the masters should provide their bondsmen or slaves with at least the necessaries of life; and, in the event of their neglecting to do so, the law, if it interfere, merely directs that they shall fulfil this natural obligation, or that otherwise they shall sell or assign their slaves to those by whom it will be fulfilled. But after the establishment of corporate bodies in the towns and cities and the growth of manufactures and commerce had given birth to a class of free labourers, the poor began to make their appearance, and to attract the notice of the legislature. Free labourers owe no compulsory service to any one. They are their own masters; and may employ themselves in any way not injurious to others they think fit. But it is plain that such persons cannot, in the event of their becoming infirm or destitute, claim to be supported by any particular individual or class of individuals. They are not bound to serve any one when in health, and, consequently, no one can be bound to provide for them when in want. Under such circumstances, they have nothing to look to but the compassionate charity of individuals or the public. But as the conduct of individuals must, in such matters, be left to be determined by their own sense of what is right and proper, we shall now, without alluding farther to them, briefly inquire what, in this respect, is the duty of the public, or whether and to what extent it should interfere to relieve the destitute.

The poor and destitute may be divided into two great classes: the first consisting of maimed and impotent persons, or of those whom natural or accidental infirmities disable from working; and the second of those who, though able and willing to work, are unable to find employment, or do not receive wages adequate for their support and that of their families. There is a very wide difference in the situation of these classes; and the same means of relief that may be advantageously afforded to the one may not, in various respects, be suitable for the other.

1. With respect, however, to the first class, or the impotent poor, there does not seem to be much room for doubt as to the policy, as well as humanity, of giving them a legal claim to relief. It has sometimes, indeed, been contended, that, by affording relief to those who are unable, from age or the gradual decay of their bodily powers, to provide for themselves, the motives that induce individuals, while in health, to make a provision against future contingencies are weakened; so that, in attempting to protect a few from the effects of their own improvidence, an injury is done to the whole community. This statement is, probably, true to a certain extent; though it be difficult to imagine that any considerable portion of a moderately intelligent population will ever be tempted to relax in their efforts to save and accumulate, when they have the means of doing so, from a knowledge that the workhouse will receive them in old age! But whatever may have been the faults of individuals, it would be abhorrent to all the feelings of humanity to allow them to suffer the extremity of want. An individual is unfortunate, perhaps, or he may not have been as thrifty or as prudent as he ought; but is he, therefore, to be allowed to die in the streets? It is proper certainly to do nothing that can really weaken the spirit of industry; but if, in order to strengthen it, all relief were refused to the maimed and impotent poor, the habits and feelings of the people would be degraded and brutalized by familiarity with the most abject wretchedness; at the same time, that, by driving the victims of poverty to despair, a foundation would be laid for the most dreadful crimes, and such a shock given to the security of property as would very much overbalance whatever additional spur the refusal of support might give to industry and economy. It does, therefore, appear sufficiently clear that this class of poor should be supported in one way or other; and that, when the parties are either without relations or friends, or when these do not come voluntarily forward to discharge this indispensable duty, the necessary funds should be provided

by a tax or rate, made equally to affect all classes; for, if they be not so raised, the poor will either not be provided for at all, or the burden of providing for them will fall wholly on the benevolent, who should not, in such a case, be called upon to contribute more than their fair share.

II. The only question, then, about which there seems to be any real ground for doubt or difference of opinion is, whether any legal claim for relief should be given to the able-bodied poor, or to those who are able and ready to work, but who cannot find employment, or cannot earn wages adequate for their support? Now this, it must be confessed, is rather a difficult question, and one which does not, perhaps, admit of any very satisfactory solution. On the whole, however, it appears, for the reasons we shall now shortly state, that it should, under certain restrictions, be decided in the affirmative.

In the first place, it may be observed, that owing to changes of fashion, to the miscalculation of producers and merchants, and to political events, those engaged in manufacturing employments are necessarily exposed to many vicissitudes; and when their number is so very great as in this country, it is quite essential that a resource should be provided for their support in periods of adversity. In the event of no such provision being made, and of the distress being at the same time extensive and severe, the public tranquillity would most likely be seriously endangered. Lord Bacon has observed, that "of all rebellions, those of the belly are the worst." It would be visionary, indeed, to imagine that those who have nothing should quietly submit to suffer the extremity of want without attacking the property of others; and hence, if we would preserve unimpaired the peace, and consequently the prosperity, of the country, we must beware of allowing any considerable portion of the population to fall into a state of destitution. But without the establishment of a compulsory provision for the support of the unemployed poor, it is difficult to see how they could avoid occasionally falling into this state. Through its instrumentality, however, they are sustained in periods of adversity, without being driven by necessity to commit crimes. It must, indeed, be admitted that a provision of this sort is very liable to abuse. Means have, however, been devised for checking this tendency; and whatever imperfections may, after all, attach to it, it has not yet been shown how security and good order could be maintained in periods when either employment or food was deficient, were it abolished.

In the second place, supposing it were possible to maintain tranquillity without making a legal provision for the support of the unemployed poor, the privations to which, under such circumstances, they would be forced to submit, would, in all probability, lower their notions as to what was necessary for their comfortable subsistence, and exert a most pernicious influence over their conduct and character. It is, perhaps, unnecessary to enter into any statements to show the importance of endeavouring to guard against any such obviously mischievous results. But Mr. Barton has made some observations on this point, which are so striking and conclusive, that we cannot forbear laying them before the reader. "It is to be remembered," says he, "that even those who most strongly assert the impolicy and injurious tendency of our poor laws, admit that causes wholly unconnected with these laws do, at times, depress the condition of the labourer. Poor families are often thrown into a state of severe necessity by long-continued illness or unavoidable misfortunes, from which it would be impossible for them to return to the enjoyment of decent competence if not supported by extraneous means. It is well known, too, that a general rise in the price of commodities is seldom immediately followed by a rise in the wages of country labour. In the meantime, great suffering must be endured by the whole class of peasantry, if no legislative provision existed for their relief; and when such a rise of prices goes on gradually increasing for a series of years, as sometimes happens, the sufferings resulting from it must be proportionally prolonged. The question at issue is simply this, whether that suffering be calculated to cherish habits of sober and self-denying prudence, or to generate a spirit of careless desperation?

"During these periods of extraordinary privation the labourer, if not effectually relieved, would imperceptibly lose that taste for order, decency, and cleanliness, which had been gradually formed and accumulated, in better times, by the insensible operation of habit and example; and no strength of argument, no force of authority, could again instil into the minds of a new generation, growing up under more prosperous circumstances, the sentiments and tastes thus blighted and destroyed by the cold breath of penury. Every return of temporary distress would, therefore, vitiate the feelings and lower the sensibilities of the labouring classes. The little progress of improvement made in happier times would be lost and forgotten. If we ward off a few of the bitterest blasts of calamity, the sacred flame may be kept alive till the tempest be past; but if once extinguished, how hard is the task of rekindling it in minds long inured to degradation and wretchedness!" (*Inquiry into the Depreciation of Agricultural Labour*, p. 32.)

In the third place, it will, we suppose, be admitted, that when a considerable number of destitute poor persons are thrown out of employment, a provision of some sort or other should be made for their support. Suppose now that it is made, not by a compulsory rate, but by the charitable contributions of the benevolent: it is contended that such a mode of relieving their distress tends to nourish the better feelings of the poor, and that many would rather choose to undergo the greatest privations than submit to solicit a share of this charitable contribution, who yet would make no scruple of claiming it had the state given them a legal right to look to it for support. But, admitting the truth of this statement, it has been already seen that it is not for the advantage of society that the poor should be forced to submit to such extraordinary privations. It is, besides, abundantly certain that many would not be influenced by the motives alluded to; and in the event of the distress being either very severe, or long-continued, even those most disinclined to become a burden on others might be forced to beg a pittance. And it is pretty obvious, notwithstanding all that has been said to the contrary, that the necessary result of such a state of things would be far more prejudicial to the character of the poor, — that it would do more to prostrate their pride and independence, and to sink them in their own estimation, than the acceptance of relief from a poor's rate. It is idle, indeed, to talk about the independence of a man who is receiving charity; but an individual supported by a poor's rate cannot fairly be regarded in such a point of view. He is merely sharing in a public provision made by the state; and as all property has been acquired with the knowledge that it was responsible to this claim on the part of the poor, it cannot justly be considered as entailing any burden on any particular individual. It may, therefore, one should think, be fairly presumed that the pride and independence of the poor will be more likely to be supported under a system of this sort, than if they were obliged to depend, in periods of distress, on the bounty of others. Wherever the poor have not either *de jure* or *de facto* a claim for support, they must unavoidably, in such periods, be allowed to beg. But of all the scourges that afflict and disgrace humanity, there is, perhaps, none more destructive than the prevalence of mendicity. A common beggar is the most degraded of beings; and the experience of Ireland, down to a very late date, as well as of France, Italy, Spain, and, in short, of every country where there is no established provision for the support of the poor, shows that wherever they are compelled to depend on so precarious a resource as charity, we look in vain for that manliness and independence of character among the labouring classes which distinguish those of England, and find in their stead all those degrading vices which a sense of insecurity, and the prevalence of beggary, are sure to produce.

The people and legislature of England have acquiesced in the justice and expediency of the principles now laid down. A compulsory provision for the support of the poor has, in fact, existed in England for a lengthened period. It grew out of the impotent attempts made in the reigns of Henry VIII., Edward VI., and the earlier part of that of Elizabeth, to suppress mendicancy, and at the same time to provide for the poor by voluntary contributions. At length the earlier statutes on the subject were consolidated, and the principle of compulsory provision carried to the fullest extent by the famous statute of the 43 Eliz. c. 2., which enacted, that all maimed and impotent persons should be provided for at the expense of their respective parishes, and that employment should be found for the unemployed able-bodied poor. From this remote period, the law of England has regarded every parish in the light of a family, the richer members of which were bound to provide for those who, through inability, misfortune, or want of work, could not provide for themselves. This, also, is the principle embodied in the law of Scotland with respect to the poor; and provided the means for carrying it into effect be so contrived that indigence and suffering may be relieved, without at the same time encouraging indolence and vice, the system would seem to be quite unexceptionable. Practically, however, this has been found to be a problem of exceedingly difficult solution, and this difficulty has made not a few conclude that, however administered, all systematic attempts to relieve the poor are necessarily, in the end, productive of increased want and misery.

The poor, no doubt, are naturally anxious that the compulsory provision for their support should be raised to the highest limit; and that their necessities should not only be relieved, but that they should be able, without molestation, to eat the bread of idleness. But wherever the assessment and administration of the provision for their support is left to the care of those on whom the burden of its payment really falls, this tendency to abuse is not long in being effectually provided against; and the sustaining and beneficial influence of the system alone

remains. The complicated code of laws respecting settlements, and the establishment of workhouses, owes its origin to this principle — to the wish of the legislature to relieve the poor, and, at the same time, to prevent the abuse of the rates; and there is unquestionable evidence to show, that, from the establishment of the system in 1603 down to about 1780, the devices in question were effectual for their object; and that while poverty was relieved, no encouragement was given to sloth, or to early and improvident unions. But soon after this period various innovations were made on the old law, which broke down most of the securities against the abuse of the rates; and, in 1795, the pernicious principle was adopted of mixing together wages and poor rates, and of eking out what was supposed to be a deficiency in the former by payments from the latter! In consequence of this subversion of the principle on which the poor rates had been previously administered, they began rapidly to increase, and threatened to swallow up the whole, or, at least, a very large part of the surplus produce of the land. Various devices were resorted to, in the view of checking the evil; but, unaccountable as it may appear, not one of them had for its object to revert to those practices and mode of administering the law which the experience of more than 250 years had shown were fully effectual for the prevention of abuse. At length the Poor Law Amendment Act was passed in 1834, which introduced a totally new system for the administration of the poor laws. Under this act the country has been divided into unions of more or fewer parishes, according to circumstances, the administration of all matters relating to the poor in these unions being intrusted to a board of guardians elected by the rate-payers. But these guardians are themselves controlled by, and in fact are merely the executive officers of, a central board of three commissioners established in London, who have power to issue rules and regulations as to the management of the poor, which all guardians, and other inferior officers, are bound to obey. The central board is assisted by deputy commissioners, who attend at meetings of guardians, explain the law, and adjudicate or report upon extraordinary cases, and see that the rules laid down by the central board are complied with. The whole that can be said in favour of this law is, that the poor rates have been materially reduced since its introduction; but we incline to think that the reduction would have been about as great had the system for the regulation of the compulsory provision that prevailed in the reign of George II. been revived, with a few alterations; while many pernicious consequences, inseparable from the existing system, would have been avoided. (See *Wealth of Nations*, M'Culloch's ed. note xxii.)

We subjoin a table of the sums expended for the relief and maintenance of the poor of England and Wales at different periods since 1748, with an estimate of the pop. at these periods: —

Years.	Sums expended on Poor.	Population.
Average.	*L.*	
1748, 1749, 1750	689,971	6,000,000
1775, 1776	1,530,800	7,000,000
1783, 1784, 1785	2,004,239	8,000,000
1801	4,017,871	8,872,000
1813	6,656,100	10,160,000
1821	6,959,249	11,978,000
1831	6,798,888	13,897,000
1835	5,526,418	14,750,000
1839	4,406,907	15,577,000

POPE. A title derived from an oriental word signifying father, and in earlier times applied indiscriminately to all bishops, and in the East even to ministers; but for many centuries the term has been confined to the bishop of Rome, who is also designated by Roman Catholics as the Holy Father. *See* PAPACY.

POPERY. *See* PAPACY.

POPLITEAL. (Lat. poples, *the ham.*) Relating to the posterior part of the knee-joint or *ham*.

POPULATION. (Lat. populus, *people.*) The inhabitants or people of any particular territory or district.

POPULATION, LAW OR PRINCIPLE OF, in Political Economy, means the law according to which the population of any country would increase, independently of immigration or emigration, under any assumed set of circumstances.

The law of population, or of the increase of the human species, has not, till a comparatively recent period, attracted that attention to which it is eminently entitled. It was formerly taken for granted that every increase of population was an advantage, and it was usual for legislators to encourage early marriages, and to bestow rewards on those who brought up the greatest number of children. But the researches of Mr. Malthus* have shown the mischievous nature of such interferences: they have shown that every increase in the numbers of a people, occasioned by artificial expedients, and which is not either accompanied or preceded by a corresponding increase of the means of subsistence, can be productive only of misery or of increased mortality; that the difficulty never is to bring human beings into the world, but to feed, clothe, and educate them when there; that mankind do everywhere increase their numbers, till their farther multiplication is restrained by the difficulty of providing subsistence, and the poverty of some part of the society; and that, consequently, instead of attempting to strengthen the principle of increase, we should rather endeavour to strengthen the principles by which it is controlled and regulated.

In order briefly to show the principle on which the increase of population depends, we may state that the sexual passion or instinct has appeared in all ages and countries so nearly the same, that it may, in the language of geometers, be called a constant quantity. Now, it has been shown by the experience of America, and of other countries under nearly similar circumstances, or where there has been a nearly equal command over the means of subsistence, that population has gone on, for a lengthened period, doubling in every twenty or five and twenty years. But the same principle or instinct that doubles the population of any particular country in this short period is every where in existence, and is every where about equally powerful. And, such being the case, it may be asked, Why does not population every where increase with the same rapidity as in Kentucky or Illinois? The reason is, that the increase of population must always depend upon, and can never for any considerable period exceed, the increase of the food and other accommodations required for the subsistence of human beings; and this increase being very different in different countries, the progress of population must vary accordingly: in some it may be rapid, in others slowly progressive, and in others stationary, or even retrograde.

It is certain, however, that the principle of increase in the species is sufficiently powerful to keep the population of the most favoured countries, or of those where wealth is most easily obtained and rapidly increased, quite up to the level of the means of subsistence. This is evinced by the poverty of a considerable portion of the people of such countries, by their usually having more claimants for employ than employers, or by the demand for labour being rather greater than that for labourers; in short, by the constant pressure, as it were, of a part of the population against the limits of subsistence. But, when such is the case, even in the most favourably situated countries, it is quite obvious that if the principle of increase were allowed to exert its full force in countries placed under less favourable circumstances, — if the same habit of early and universal marriage were indulged in the latter as in the former, it could not fail to occasion the most deplorable results. Man cannot increase beyond the means of subsistence; and where these are either stationary, or but slowly advancing, any such development of the principle of increase as is exhibited in countries where these means are increasing most rapidly would be productive only of increased misery and mortality. And hence, in the vast majority of cases, the principle of increase is restrained and controlled by prudential considerations. Man is not, like the lower animals, actuated only by instinct. To occasion a marriage, it is not always enough that the parties should be attached to each other. The obligation of providing for the children that may be expected to spring from it, is one that cannot fail to awaken the forethought and to influence the conduct of all but the most improvident and thoughtless. If the situation of those who might be disposed to enter into a matrimonial alliance be such as to preclude all reasonable expectation of their being able to bring up and educate their children, without exposing themselves to privations, or to the risk of being cast down to a lower place in society, they may not improbably either relinquish all thoughts of forming a union, or postpone it till a more convenient opportunity. No doubt there are very many individuals in all countries who are not affected by such considerations, and who, seeing the future through the deceitful medium of their passions, are not deterred from gratifying their inclinations by any fear of the consequences. But the great majority of every society act on sounder principles. They are anxious not to preserve merely, but to improve their condition in society, and cannot bear the idea that their family should be in a worse situation than themselves. Hence the reason that in all old settled or densely peopled countries, marriages are deferred to a much later period than in colonies and newly settled countries, where there are comparatively great facilities for gaining a livelihood, and that a much larger proportion of the population find it expedient to pass their lives in celibacy. And it is fortunate that such is the case, — that the forethought and good sense of the people, and their laudable wish to maintain and better their condition, make them control

* Essay on the Principle of Population, *passim*. The first edition of this work was published in 1798.

the violence of their passions, and disregard the dicta of spurious advisers. It is quite obvious that if the capacity of multiplication, or the principle of increase, in densely peopled countries, where there is a comparatively great difficulty in obtaining supplies of food, were not checked by the prevalence of moral restraint, arising from the consideration of the circumstances under which society is placed, it would occasion the constant pressure of misery and famine. There is no alternative. The population of every country has the power, supposing food and other necessary accommodations to be adequately supplied, to go on doubling every twenty or five and twenty years; but as the limited extent and limited fertility of the soil render it impossible to go on permanently producing food in this ratio, it unavoidably follows that unless the passions be moderated, and a proportional diminution be effected in the number of marriages and births, the standard of subsistence will be reduced to the lowest assignable limit, and famine and pestilence will be perpetually at work to relieve the population of wretches born only to be starved.

Although, therefore, the principle or instinct which prompts to the increase of the species be alike powerful in the most opposite conditions and states of society, its development depends on a variety of circumstances. Generally, however, there can be no question that it is sufficiently powerful, even where the means of subsistence are acquired with the greatest ease, to keep population on a level with these means; and in all but the most favoured situations, it could hardly fail, if not controlled by other circumstances, to make the increase of population outrun that of the means of subsistence, and, consequently, to occasion an increase of misery and mortality. But this tendency is seldom or never allowed to exert its full influence. The principle of increase, though one of the strongest implanted in our nature, is, after all, governed less by instinct than by reason. At all events, it is invariably found, when we look at nations or great masses of individuals, that the period and frequency of marriages and the rate of increase are determined by the state of the population with respect to food, and that the latter is never outrun by the former.

The principle of increase is not, therefore, the bugbear, the invincible obstacle to all real improvement it has been represented by those who have overlooked the influence of moral causes in modifying and controlling its action. That the tendency to increase is not inconsistent with the improvement of society is a fact, as to which, indeed, there can be no dispute. Without going back to antiquity, let any one compare the state of this or any other European country 500 or 100 years ago with its present state, and he will be satisfied that prodigious advances have been made, that the means of subsistence have increased much more rapidly than the population, and that the labouring classes are now generally in the possession of conveniences and luxuries that were formerly not enjoyed even by the richest lords. The principle of increase is not, however, merely consistent with the continued improvement of the bulk of society—it is, in fact, the great cause of this improvement, and of the wonderful progress made in the arts. Had the principle been less powerful, or had it not existed at all, every new discovery, by diminishing the necessity for others, would have occasioned a decline in the spirit of invention; and society would long since have been either in a languishing or a stationary state. But the increase of population, though generally subordinate to the increase of food, is always sufficiently powerful to keep invention on the stretch. All that numerous class who live by their labour, and who are either striving to raise themselves to a higher station, or to maintain their present position, are at this moment impelled by the same powerful motives to invent and contrive new and more powerful methods of production that impelled their ancestors 5,000 years ago; and so it will be in all time to come. The *curis acuens mortalia corda* will never cease to operate, and will secure the continued advancement of society. To suppose, as some have done, that the extraordinary progress already made in science and the arts would have been equal or greater had the tendency to increase been less powerful, is in truth equivalent to supposing that industry and invention would be promoted by lessening the motives to their exercise, and the advantages derivable from them. There might, perhaps, have been less squalid poverty among the very dregs of the population, had there been no principle of increase; but it is a contradiction to pretend, had such really been the case, that the powers and resources of industry would have been so astonishingly developed, that scientific investigations would have been prosecuted with equal perseverance and zeal, that so much wealth would have been accumulated by the upper and middle classes, or that the same circumstances which urged society forward in its infancy would have continued in every subsequent age to preserve their energy unimpaired; and it may well be doubted whether an exemption from the evils incident to poverty would not have been dearly purchased, even by the very lowest classes, by the sacrifice of the hopes and fears attached to their present condition, and the extraordinary gratification they now reap from successful industry.

If these conclusions be well founded, it follows that the schemes proposed for directly repressing population in the ancient and modern world, besides being for the most part atrocious and disgusting, have really been opposed to the ultimate objects their projectors had in view. Could the rate of increase be subjected to any easily applied physical control, few comparatively among the poorer classes would be inclined to burden themselves with the task of providing for a family; and the most effective stimulus to exertion being destroyed, society would gradually sink into apathy and languor. It is, therefore, to the principle of moral restraint, or to the exercise of the prudential virtues, that we should exclusively trust for the regulation of the increase of population. In an instructed society, where there are no institutions favourable to improvidence, this check is sufficiently powerful to confine the progress of population within due limits, at the same time that it is not so powerful as to hinder it from operating, in all cases, as the strongest incentive to industry and economy.

Mr. Malthus's *Essay on Population* made a great sensation at the time when it appeared, and is valuable from its showing conclusively that the principle of increase is strong enough, without any adventitious encouragement, to keep population always on a level with the means of subsistence. In other respects, however, it is altogether defective. Mr. Malthus has not shown that the mischievous consequences that might otherwise result from the operation of the principle of increase are sure to be countervailed by the operation of those prudential considerations to which it necessarily gives rise; nor has he shown the important and powerful influence of the principle in securing the continued improvement of society. One of the best expositions of the theory of population is that given by Bishop Sumner in his *Records of the Creation*. See also the note on Population in M'Culloch's edition of the *Wealth of Nations*.

PO'PULIN. A crystallizable substance separated from the bark of the *Populus tremula*.

PO'RCATE. (Lat. porca, *a ridge*.) In Entomology, when a surface has several parallel elevated longitudinal ridges.

PORCELAIN. *See* POTTERY.

PORCELLANITE. An opake brittle variety of jasper.

PORCH. (Fr. porche.) In Architecture, an arched or flat or ceiled vestibule at the entrance of a church or other building.

PORES. In Natural Philosophy, the small interstices between the particles or molecules of matter which compose bodies. There are many considerations which prove that all bodies, even the densest, are composed of molecules, not in absolute contact, but separated from each other by intervals, which, though so small as to be inappreciable to the senses, have, nevertheless, a magnitude considerable in respect of the molecules themselves. The porosity of bodies may be demonstrated in many cases by very simple experiments. If a piece of wood, or marble, granite, or other compact stone, be plunged under water and placed under the receiver of an air-pump, on withdrawing the external pressure the air which had been dispersed through the interior cavities, or pores, will issue from every point of their surface, and rise in a torrent of bubbles. In like manner, mercury is forced through a piece of dry wood or leather, and made to fall in a finely divided shower. A body plunged deep under a liquid sustains a pressure, in consequence of which it is contracted in all its dimensions, and the liquid penetrates the body without producing any apparent disruption of its parts. Iron, by being hammered, is reduced in volume; and the dimensions of all bodies are affected by heat and cold. The facility with which translucent substances are penetrated by the rays of light evinces extreme porosity. And this penetration is not confined to bodies which are usually termed diaphanous; for gold itself, one of the most opake of the metals, when beaten into extreme thinness, transmits a soft green light. All these facts prove the existence of pores; and it has been inferred that gold has more pores than solid parts; whence water, or any substance of the same specific gravity, must have many times more pores than solid parts.

PORI'FERA. (Lat. porus, *a pore*, and fero, *I carry*.) A name invented and applied by Mr. Hogg to a group of Polyps, including the genera *Cellepora*, *Millepora*, and *Tubulipora*: also used by Dr. Grant to designate the class of organized beings including the marine and fresh-water sponges.

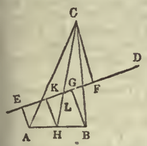
PO'RISM. (Gr. *πορισμα*; from *ποριζω*, *I investigate*), in Geometry, is defined by professor Playfair to be "a proposition affirming the possibility of finding such conditions as will render a certain problem indeterminate, or capable of innumerable solutions."

According to Pappus, the porisms constituted one of

the eight subjects which formed the ancient geometrical analysis. Euclid composed a treatise on porisms in three books, of which no trace now remains, except some obscure hints preserved in the mathematical collections of Pappus. From the manner in which the porisms are mentioned by Pappus, it is evident that the ancients set a high value on this class of propositions; but the description which he has given of them is so vague that geometers were long unable to divine his meaning, or to discover the peculiar circumstances in respect of which a porism differs from an ordinary problem. The subject, indeed, baffled the ingenuity of the most eminent mathematicians, until it was taken up by Dr. Simson, of Glasgow, who at length succeeded in restoring a great number of Euclid's porisms, together with their analysis. The propositions thus restored form a part of his posthumous works, published in 1776, at the expense of Earl Stanhope. It still remained, however, to inquire into the probable origin of the porisms, or the steps by which the ancient geometers had been led to their discovery; and also to point out the relations in which they stand to other classes of geometrical truths. This was accomplished by the late Professor Playfair, in an admirable paper, "On the Origin and Investigation of Porisms," published in vol. iii. of the *Transactions of the Royal Society of Edinburgh*, and afterwards in the 3d volume of his collected Works, Edin. 1822.

The nature of a porism, and the manner in which it is derived from an ordinary proposition, will be best illustrated by an example. The following proposition is one of those selected by Mr. Playfair for the purpose: —

A triangle A B C being given, and also a point D; to draw through D a straight line D E, such that perpendiculars being drawn to it from the three angles of the triangle, namely, A E, B G, C F, the sum of the two perpendiculars on the same side of D E shall be equal to the remaining perpendicular, or that A E and B G together shall be equal to C F.



Suppose it done; bisect A B in H, join C H (intersecting D E in L), and draw H K perpendicular to D E.

Because A B is bisected in H, the two perpendiculars A E and B G are together double of H K; and, as they are equal to C F, by hypothesis, C F must also be double of H K, and C L of L H. Now C H is given in position and magnitude, therefore the point L is given; and the point D being also given, the line D L is given in position, which was to be found.

The construction is obvious. Bisect A B in H, join C H, and take H L equal to one third of C H; the straight line which joins the points D and L is the line required.

Now, it is plain that while the triangle A B C remains the same, the point L also remains the same, wherever the point D may be. The point D may therefore coincide with L; and, when this happens, the position of the line to be drawn remains undetermined; that is to say, any line whatever drawn through L will satisfy the conditions of the problem. Here, then, we have an indeterminate case of a problem, and, of consequence, a porism, which may be thus enunciated: —

A triangle being given in position, a point in it may be found such that any straight line whatever being drawn through that point, the perpendiculars drawn to this straight line from the two angles of the triangle which are on one side of it, will be together equal to the perpendicular that is drawn to the same line from the angle on the other side of it.

For examples of porisms, see *Simson's Opera Reliqua;* Playfair's paper above mentioned; a paper by Prof. Wallace, entitled "Some Geometrical Porisms, &c." in the *Edinburgh Transactions*, vol. iv.; *Stewart's General Theorems*, 1746; *Leslie's Geometrical Analysis;* and *Leybourn's Mathematical Repository*. See also *Traill's Account of the Life and Writings of Robert Simson, M.D.;* and Chasles, *Aperçu Historique sur l'Origine et le Développement des Méthodes en Géometrie*, Brux. 1837.

The term porism is also used by the Greek geometricians to signify merely the corollary to a proposition.

PORO'SITY. A property of matter, in consequence of which its molecules are not in absolute contact, but separated by intervals or *pores*. The quantity of matter in a body is inversely as its porosity; whence the ratio of the porosity of one body to another may be determined from their weight. *See* PORES.

PO'RPHYRY. (Gr. πορφυρα, *purple*.) In Statuary, an extremely hard stone of a red, or rather purple and white colour, more or less variegated, its purple being of all gradations, from violet to a claret colour. It is susceptible of a very high polish. Egypt and the East furnish very plentiful strata of this material. It is also found in Minorca. The extreme ease with which the ancients seem to have cut this substance and worked it in sculptural subjects has been a matter of much discussion among the moderns. Dr. Lister, in a paper of the *Philosophical Transactions*, seems to think that the ancients possessed the secret of tempering steel better than the moderns. The French cut it with an iron saw without teeth, using a kind of freestone pulverized and mixed with water. And Cosmo di Medici is said to have distilled a water by the help whereof Francesco Taddi, his sculptor, gave his tools a hardness and temper capable of working the hardest and most compact substances.

PORPHYRY. In Geology, an unstratified or igneous rock containing embedded crystals of felspar. The term was originally applied to a *red* rock of this kind found in Egypt, alluded to in the preceding article. *See* GEOLOGY.

PO'RPITA. (Gr. πορπη, *Annulus clypei.*) The name of a genus of sea-nettles (*Acalephæ*), characterized by an internal circular flattened disk of a calcareous and horny texture.

PORRECT. (Lat. porrigo, *I extend.*) In Zoology, when a part extends forth horizontally, as if to meet something.

PORRI'GO. (Lat. porrigo.) The ringworm, or scald-head.

PORT. *See* HARBOUR.

PORT is, usually, the adverb of larboard; as, the ship heels *to port*, for to the larboard side. Put the helm *a-port*, &c.

PORT. The opening or embrasure in the ship's side for a gun. The ports of the lower deck are defended, when at sea, by strong covers hanging from hinges; the ropes by which these are held up or open are called *port lanyards*, and consist of a pendant passing through a leaded hole in the side with a tackle.

PORTAL. (Fr. portail.) In Architecture, the lesser of two gates, when they are of two dimensions, at the entrance of a building.

PORTCU'LLIS. (Fr. portecoulisse.) In Fortification, a sort of machine composed of several large pieces of wood laid across one another, like a harrow, and pointed with iron, used formerly to be hung over gateways of fortified places, to be let down in case of a surprise, and when there was not time to shut the gate.

PORTE, THE SUBLIME. The official title of the government of the Ottoman Empire: said to be derived from a gate of the palace at Broussa, the original metropolis of that empire, called Bâb Humayoor, the sublime gate.

PO'RTER. A liquor brewed from malt, part of which has been more highly dried than that used for ale. It is hopped in the same way as ale; and its deep colour is finally given to it either by burned sugar, which usually goes under the name of *colouring*, or more legitimately by roasted or parched malt. Porter was first brewed in 1722. The malt liquor previously drunk consisted of three kinds — ale, beer, and "twopenny;" and a mixture of either of these kinds was a favourite beverage under the name of "half-and-half;" or a mixture was drunk called "three threads," consisting of equal portions of each of the above kinds of liquor, for a draught of which the publican had to go to three different casks. About 1722, Harwood, a London brewer, commenced brewing a malt liquor, which was intended to unite the flavours of ale and beer, or ale, beer, and "twopenny;" and having succeeded, he called his liquor "entire," or "entire butt;" a name intended to intimate that it was drawn from one cask or butt only. A mixture of ale or porter, drawn from different casks, is very commonly drunk in London at the present time. Harwood's liquor obtained the name of porter from its consumption by porters and labourers. From 1722 to 1761, the retail price of porter was 3*d.* per pot, when it was raised to 3½*d.*, at which it continued till 1799; it has never been higher than 6*d.*, nor during the present century lower than at the present time (September, 1841), when the price is 4*d.* The following account of the fluctuations of the price per barrel since 1816 is from a private source: — In July, 1816, the price was reduced from 45*s.* to 40*s.*, but in October was again advanced to 45*s.*; in January, 1817, a further advance was made to 50*s.*; and in December of the same year it reached 55*s.* In 1819, 1820, and 1822, the price was successively reduced from 55*s.* to 50*s.*, 45*s.*, and 40*s.* In January, 1824, it was advanced to 45*s.*; in November, 1825, to 50*s.*; but a few months afterwards it again fell to 45*s.* Since the abolition of the beer duties in 1830, the price has been 33*s.* per barrel.

PORT-FIRE. In Gunnery, a paper tube about 10 inches long, filled with a composition of meal-powder, sulphur, and nitre, rammed moderately hard; used to fire guns and mortars instead of a match. (*Hutton's Dict.*)

PO'RTICO. (Ital.; from porticus, Lat.) In Architecture, a place for walking in under shelter, occasionally raised after the manner of a gallery with arches. Sometimes the portico is vaulted, and sometimes it is with a flat ceiling. The most usual application of the word is to the projection supported by columns placed before a building.

PO'RTIO, or PORTION, is a term anatomically ap-

plied to two branches of the seventh pair of nerves; the *portio dura*, or hard portion, and the *portio mollis*, or soft portion: the former is the facial nerve, the latter the auditory or acoustic nerve.

PO'RTLAND POWDER. A mixture of several indigenous bitter herbs which was once a celebrated remedy in the gout.

PO'RTLAND STONE. A granular limestone belonging to the upper part of the oolite formation, and abounding in the island of Portland, upon the coast of Dorsetshire. *See* GEOLOGY.

PORTLAND VASE. A celebrated cinerary urn or vase, long in possession of the noble family of the Barberini at Rome (whence it was called the Barberini vase); from whom it came into the possession of the Portland family, who deposited it in 1810 in the British Museum, of which it is one of the most valuable reliques. This beautiful specimen of ancient art was found in the tomb of the Emperor Alexander Severus and his mother Mammæa. It is described by Montfauçon (*Antiq. Expliqué*, tom. v.), who was evidently mistaken in representing it as formed of a precious stone. The substance is said to be of glass, or composition; it is of a deep blue or violet colour, and the figures in the scene depicted on it are white. The subjects are mythological, but have been very imperfectly explained. (See two memoirs upon it, by Dr. King and W. Marsh, in the 8th volume of the *Archæologia*, and one by Dr. Darwin in the Notes to his *Botanic Garden*.) The late Mr. Wedgwood made a mould of this vase, and took from it a number of casts made with the greatest skill, and perfectly resembling the original.

PO'RTRAIT. (Fr. pourtrait.) In Painting, the representation of an individual, or, more strictly speaking, of a face, painted from real life. Portraits are of full length, half length, &c.; and are executed in oil or water colours, crayons, &c.

PORTREE'VE, or PORT GREVE. (Ang. Sax. gerefa.) Anciently the principal magistrate in ports and maritime towns. According to Camden, this was the ancient title of the officer who was afterwards called mayor in London.

PORT ROYALISTS. The name popularly given to the members of the celebrated convent of the Port Royal des Champs. It was founded about 1204 by Matthieu de Marli, on the eve of his departure for the Holy Land; and though originally limited in its means and objects, it gradually acquired such importance as to have secured for it a prominent place in the history of Europe. It would be out of place here to give any details of its varied fortunes, and the religious controversies which it carried on in the 17th century — the period of its greatest importance; and we refer the reader to the learned work of Reuchlin (*Geschichte von Port Royal*), for full information. (See also the eloquent article in vol. lxxiv. of the *Edin. Review*.) It was abolished by Louis XIV., as a nest of Jansenists and heretics. Among the distinguished names connected with the Port Royal are those of Lancelot, Paschal, Arnauld, Nicole de Sacy, and Tillemont. The school books which were published for the use of that institution were translated into all the languages of Europe, and maintained their reputation long after its abolition; and though they are now fallen into disuse, the following deserve especial mention: — 1. *Nouvelle Méthode pour apprendre la Langue Latine*; 2. *Nouvelle Méthode pour apprendre la Langue Grecque*; 3. *Grammaire Générale, &c.*

POSI'TION. (Lat. pono, *I place*.) A rule in Arithmetic, called also the rule of supposition, or *rule of false*. It consists in assuming a number, and performing upon it the operation described in the question, and then comparing the result with that given in the question, in order to discover the error of the assumption. Writers on arithmetic divide the rule into two parts, *single position* and *double position*; the former comprehending those questions in which the results are proportional to the suppositions, and where, consequently, only one assumption is required; the latter those in which the results are not proportional to the suppositions, and where two suppositions are necessary in order to deduce the true answer. To simple position belong such questions as the following: — What number is that from which, if a third and a fourth of itself be subtracted, the remainder is 60? Double position comprehends questions of this sort: — What number is that which, being multiplied by 6, the product increased by 18, and the sum divided by 9, the quotient shall be 20? It will be observed that both these questions are immediately solved by a simple algebraic equation; and, in fact, the same process is performed in the arithmetical operation in the assured number, which, in the algebraic, is performed on the unknown quantity. The rules given for the solution of questions in double position are founded on certain principles of algebra, which may be applied with much greater facility to the immediate solution of the questions themselves. Such questions, therefore, cannot be considered as properly belonging to arithmetic, but to what may be denominated numerical analysis. Position is also called the *rule of trial and error*, and is sometimes employed with good effect in approximating to the roots of numerical equations.

POSITION. In Painting, the placing of the model in the manner best calculated for the end in view by the artist. Such positions as are most natural and easy, and which exhibit the peculiar habit of the individual, in portrait painting, are preferable.

POSITIVE ELECTRICITY. *See* ELECTRICITY.

POSITIVE QUANTITY, in Algebra, denotes an affirmative or additive quantity; which character is indicated by the sign +, called, in consequence, the *positive sign*. The term is used in contradistinction to *negative*; negative quantities being such as are subtractive, and marked by the sign —, which is called the *negative sign*. *See* SIGN.

PO'SSE COMITA'TUS. (Lat.) In Law, the power of the county, which the sheriff is empowered to raise in case of riot, possession kept on forcible entry, rescue, or other force made in opposition to the king's writ or execution of justice. It is said to include all knights and other men, above the age of fifteen, able to travel within the county. Justices of the peace may also raise the posse in order to remove a force in making entry into or detaining lands.

POST. (Fr. poste.) In Architecture, any vertical piece of timber; as a truss post, door post, a quarter in a partition.

POST. In Public Economy, a messenger, courier, or conveyance that travels at stated periods, and generally with more than ordinary speed, employed to convey letters or other despatches, whether of government or individuals.

POST-ABDOMEN. (Lat.) The name applied by Latreille to the five posterior segments of the abdomen of Hexapod insects; and to the tail of Crustaceans, which consists of analogous but more numerous segments.

POSTAGE. The duty or rate of charge levied on letters or other articles conveyed by post.

PO'STEA. (Lat.) In Law, the return of the judge before whom a cause is tried, after verdict, of what was done in the cause, which is endorsed on the back of the nisi prius record.

PO'STERN. (Fr. posterne.) In Architecture, a small gate or door at the back of a building.

POSTERN. In Fortification, a small gate, usually made in the angle of the flank of a bastion, or in that of the curtain.

POSTI'LUM. (Lat.) In Architecture, the portico at the back of a temple. *See* NAOS.

POSTLIMI'NIUM, or JUS POSTLIMINII. (Lat. limen, *a threshold*.) In National and Civil Law, the right by virtue of which persons taken by an enemy return to their former state of freedom, with their former rights and property, on its termination; and property so taken reverts to its former owners.

POST OBIT. (Lat. post obitum, *after death*.) A bond given for the purpose of securing a sum of money on the death of some specified individual.

POST OFFICE. A place for the reception and distribution of the letters and despatches that are to be or that have been carried by the post; where the duties on them are paid, and where the various departments connected with the business of the post are conducted, or superintended.

The conveyance of letters by post is one of the few industrious undertakings which are certainly better managed by government than they could be by individuals. It is indispensable to the satisfactory working of the post office that it should be conducted with the greatest regularity and precision; and that all the departments should be made subservient to each other, and conducted on the same plan. It is plain that such results could not be obtained in any extensive country otherwise than by the agency of government; and the interference of the latter is also required to make arrangements for the safe and speedy conveyance of letters to, from, and through foreign countries.

The organization of the post office supplies one of the most striking examples of the advantages resulting from the division and combination of employments. "Nearly the same exertions that are necessary to send a single letter from Falmouth to New York will suffice to send 50,000. If every man were to effect the transmission of his own correspondence, the whole life of an eminent merchant might be passed in travelling, without his being able to deliver all the letters which the post office forwards for him in a single evening. The labour of a few individuals, devoted exclusively to the forwarding of letters, produces results which all the exertions of all the inhabitants of Europe could not effect, each person acting independently." (*Senior on Political Economy*.)

Posts appear to have been established for the first time in modern Europe in 1479, by Louis XI. of France. They were originally intended to serve merely for the conveyance of public despatches, and of persons travelling by authority of government. Subsequently, however, private individuals were allowed to avail themselves of

this institution for forwarding letters and despatches; and governments, by imposing higher duties or rates of postage on the letters and parcels conveyed by post than are sufficient to defray the expense of the establishment, have rendered it productive of a considerable revenue. Nor, while the rates of postage are confined within reasonable limits, and do not materially affect the facility of correspondence, is there, perhaps, a less objectionable tax.

The post office was not established in England till the 17th century. Post-masters, indeed, existed in more ancient times; but their business was confined to the furnishing of post horses to persons who were desirous of travelling expeditiously, and to the despatching of extraordinary packets upon special occasions. In 1635, Charles I. erected a letter office for England and Scotland; but this extended only to a few of the principal roads; the times of carriage were uncertain; and the post-masters on each road were required to furnish horses for the conveyance of the letters at the rate of $2\frac{1}{2}d.$ a mile. This establishment did not succeed; and, at the breaking out of the civil war, great difficulty was experienced in the forwarding of letters. At length a post office, or establishment for the weekly conveyance of letters to all parts of the kingdom, was instituted in 1649, by Mr. Edward Prideaux, attorney-general for the Commonwealth; the immediate consequence of which was a saving to the public of 7,000*l.* a-year on account of post-masters. In 1657, the post office was established nearly on its present footing, and the rates of postage that were then fixed were continued till the reign of Queen Anne. (*Black. Com.*, book i. c. 8.)

From the establishment of the post office by Cromwell, down to 1784, mails were conveyed either on horseback, or in carts made for the purpose; and instead of being the most expeditious and safest conveyance, the post had become, at the latter period, one of the slowest and most easily robbed of any in the country. In 1784, it was usual for the diligences between London and Bath to accomplish the journey in *seventeen* hours, while the post took *forty* hours; and on other roads the comparative rate of travelling of the post and stage coaches was in about the same proportion. The natural consequence of such a difference in point of despatch was, that a very great number of letters were sent by other conveyances than the mail: the law to the contrary being easily defeated, by giving them the form of small parcels.

Under these circumstances, it occurred to Mr. John Palmer of Bath, comptroller-general of the post office, that a very great improvement might be made in the conveyance of letters, in respect of economy, as well as of speed and safety, by contracting with the proprietors of stage coaches for the carriage of the mail; the latter being bound to perform the journey in a specified time, and to take a guard with the mail for its protection. Mr. Palmer's plan encountered much opposition, but was at length carried into effect with the most advantageous results. The use of mail-coaches speedily extended to most parts of the empire; and, while letters and parcels were conveyed in less than half the time that had been required under the old system, the coaches by which they were conveyed afforded, by their regularity and speed, a most desirable mode of conveyance for travellers. Mr. Palmer was the author of several other improvements in the economy of the post-office; nor is there any individual to whom the department owes more. (*Macpherson's Annals of Com.* anno 1784.)

Within the last few years, however, the construction of railways between most of the great towns of the empire has gone far to supersede the use of mail coaches on the principal lines of road, and has added prodigiously to the facilities of correspondence and travelling. The journey from London to Liverpool, which had been accomplished by the mail in about twenty or twenty-two hours, is now accomplished, by railway, in nine or ten hours! and on other roads in the same proportion. The great expense of the post office consists, in fact, not so much in the conveyance of letters from place to place, as in their previous collection and their distribution after they have been conveyed to their destination. This necessitates the establishment of a vast number of subordinate offices in the remoter parts of the kingdom, many of which do not defray their expenses. This is particularly the case in Ireland, where, in 1838, the expense of collecting the gross post office revenue amounted to 39*l.* 16*s.* $4\frac{1}{2}d.$ per cent.

Revenue and Rates of Postage. — During 1838 the post office of the United Kingdom produced a gross revenue of 2,346,278*l.*, and a nett revenue, after deducting the expense of collection, of 1,676,522*l.* This large revenue was derived from rates of postage, varying with the distance according to which letters were conveyed, but so that at an average they amounted to about 7*d.* or $7\frac{1}{2}d.$ for a single letter. But the fact that the post office revenue had continued nearly stationary during the twenty years ending with 1838, notwithstanding the vast increase in that period of population and of the intercourse between the different parts of the empire, was a conclusive proof that the rates of postage had been carried to a vicious excess; and that in the arithmetic of the post office, as well as of the customs, two and two, instead of always making four, sometimes make only one. The effectual reduction of these rates was therefore urgently required, not only because of the importance to a commercial and manufacturing community of having the charge for the conveyance of correspondence fixed at a moderate amount, but because it was all but certain that moderate rates of postage would be more productive of revenue. It did not, however, follow, that because an average charge of 7*d.* or $7\frac{1}{2}d$ each on all letters conveyed by post was very decidedly too much, that the plan for making an invariable charge of 1*d.*, whether the letter were conveyed one mile or 1000 miles, should have been adopted. This was to rush from one extreme to another, and to endanger a considerable amount of revenue without any equivalent advantage. It must, no doubt, be admitted that the proposal for a uniform penny rate of postage, had many recommendations in its favour. Being calculated at once to obviate trouble and save expense, it could not fail to be acceptable (what reduction of taxation is not?) to a large portion of the public, particularly to persons engaged in business. We believe, however, that the scheme was more indebted for its popularity to the oppressiveness of the old rates of postage than to any intrinsic merits of its own. Had these been reduced four or five years previously to a reasonable amount, that is, had letters of 1 oz. weight coming from Scotland or Ireland to London been reduced to 6*d.*, and other letters in proportion, and mercantile circulars been allowed to pass under covers open at the ends at 1*d.* or 2*d.* each, we venture to say that the clamour for a uniform rate of penny postage would not have made any way. But in this, as usually happens on similar occasions, those who delay to make reasonable and necessary concessions at the outset, are in the end compelled to concede a great deal more than would at first have been satisfactory. This, at all events, has been eminently true in the present instance. The clamour for a uniform penny rate became too powerful to be resisted; and parliament, whether it were so inclined or not, was obliged to lend its sanction to the measure And under the provision of the act 2 & 3 Vict. cap. 52., it has been enacted that all inland letters, without regard to the number of enclosures, or the distance conveyed, provided they be paid when posted or despatched, shall, if not exceeding $\frac{1}{2}$ oz. weight, be charged 1*d.*; 1 oz. 2*d.*; 2 oz. 4*d.*; 3 oz. 6*d.*; and so on; 2*d.* being added for every additional ounce up to 16 oz., beyond which, with the following exceptions, no packet, whether subject to postage or not, is received: —

1. Parliamentary petitions and addresses to her Majesty.
2. Parliamentary proceedings.
3. Letters and packets addressed to or received from places beyond sea.
4. Letters and packets to and from public departments, and to and from public officers that formerly franked by virtue of their offices.
5. Deeds, if sent open, or in covers open at the sides. They may be tied with string and sealed, in order to prevent inspection of the contents; but they must be open at the sides, that it may be seen that they are entitled to the privilege.

With these exceptions, all packets above the weight of 16 oz. will be immediately forwarded to the Dead Letter Office.

But all letters not paid when they are posted or despatched are charged *double the above rates*.

All parliamentary and official franking has been put an end to; but members of either house of parliament are entitled to receive petitions to parliament free of charge, provided such petitions be sent in covers open at the ends, and do not exceed 6 oz. weight.

To facilitate the working of the plan, envelopes and stamps for single, double, &c. letters, are furnished by the post office, and have been widely distributed.

Such are the more prominent features of the new system; and none can deny that it has the recommendations of simplicity and cheapness in its favour, and that it has greatly facilitated correspondence. But it may nevertheless be doubted whether its adoption was expedient. It is certainly very convenient for merchants, bankers, middlemen, and retail dealers, to get letters for 1*d.*, that previously cost them 7*d.* or $7d\frac{1}{2}$.; but their satisfaction is not the only thing to be attended to in forming a fair estimate of the measure. The public exigencies require that a sum of above fifty millions a year should be raised, one way or other; and so long as we are pressed by an unreasoning necessity of this sort, it is not much to say in favour of the repeal or diminution of any tax, that those on whom it fell with the greatest severity are delighted with the reduction. Sugar has in England become a necessary of life; and its consumption, to say the least of it, is quite as indispensable to the bulk of the people, and especially to the labouring classes, as the

writing of letters. But would it, therefore, be a wise measure to repeal the duty on sugar, or to reduce it to 1s. a cwt.? It has been alleged, indeed, that taxes on the transmission of letters are objectionable on principle, and should therefore be repealed, independently altogether of financial considerations. But it is easier to make an allegation of this sort than to prove it. All taxes, however imposed, if they be carried (as was the case with the old rates of postage) beyond their proper limits, are objectionable; but provided these be not exceeded, we have yet to learn why a tax on a letter should be more objectionable than a tax on the paper on which it is written, on the food of the writer, or on fifty other things.

During the first year (1840) of the new system, the nett revenue of the Post Office fell off about 1,200,000*l*.! No doubt, however, the revenue will increase in subsequent years, with the increasing population and wealth of the country. But it would have done this under any system of moderate duties; and its future increase, whatever it may be, is consequently no proof of the superiority of the present system.

POST POSITION. In Music, retardations of the harmony, effected by placing discords upon the accented parts of a bar not prepared and resolved according to the rules for discords.

POSTSCE'NIUM. (Lat. post, *behind*, and scena, *a scene*.) In Architecture, the back part of the theatre behind the scenes, furnished with conveniences for robing the actors and depositing the machinery.

PO'STULATE. (Lat. postulare, *to demand*.) In Geometry, something to be assumed, or taken for granted. Euclid has constructed his *Elements* on the three following postulates: — 1. That a straight line may be drawn from any one point to any other point. 2. That a terminated straight line may be produced to any length in a straight line. 3. That a circle may be described from any centre at any distance from that centre. (*Playfair's Euclid*.)

Postulate. In Logic and Philosophy, a proposition of which the truth is *demanded* or assumed for the purpose of future reasoning.

POTA'SH. The saline matter obtained by lixiviating the ashes of wood. When purified by calcination it is termed *pearlash*, and is in that state an impure *carbonate of potassa*. The production of potash is carried on upon a large scale in Russia and America; it can only be thus obtained in countries where there are vast natural forests, and where the value of timber is little more than that of the labour of felling it. *See* Potassium.

POTASSA. *See* Potassium.

POTA'SSIUM. This extraordinary metal was discovered by Davy in the year 1807, and was one of the first fruits of his masterly researches into the chemical powers of electricity. Its properties are so remarkable, that it was for a time doubted whether it could with propriety be placed among the metals; but the progress of discovery has removed all difficulty upon that point, by making us acquainted with other metallic substances, the properties of which are, as it were, intermediate between those of potassium on the one hand, and the common metals on the other. One of the striking peculiarities of potassium is mechanical rather than chemical, namely, its low specific gravity, it being the lightest known solid; another is its intense affinity for oxygen, and its consequent energetic action when placed upon water, where it immediately takes fire. The specific gravity of potassium is ·865 at the temperature of 60°.; it is solid at the ordinary temperature of the atmosphere; at 80° it becomes soft, and at 150° is perfectly liquid; at 32° it is brittle, and has a crystalline texture. In colour and lustre it resembles mercury. Its attraction for oxygen is such that it immediately loses its brilliancy on exposure to air, and becomes converted into potassa; heated in the air it burns with a purple flame. The equivalent of potassium is 40, and that of *potassa* or *protoxide of potassium* is 48. When potassium is heated in oxygen it absorbs a larger quantity of that element and becomes a *peroxide*, which, however, is immediately converted into protoxide by the action of water. Protoxide of potassium exists in the state of *hydrate* in what is called *caustic potash*, which is a compound of 48 potassa + 9 water. This substance fuses at a dull red heat: it is very soluble and deliquescent, and powerfully corrodes almost all animal textures. It is the *lapis causticus* of old pharmacy. Dissolved in water it forms *soap ley*, or the *liquor potassæ* of the Pharmacopœia. This solution is obtained by pouring water upon a mixture of equal parts of quicklime and carbonate of potassa; the lime abstracts carbonic acid from the carbonate, and becomes converted into an insoluble carbonate of lime, whilst the evolved potassa is taken up by the water. The solution thus obtained is powerfully alkaline and caustic; and, as it soon absorbs carbonic acid when exposed to air, it should be carefully preserved in well-stopped phials. Free potassa is easily detected and recognized, when in solution, by its alkaline reaction upon proper vegetable colours, rendering, for instance, the yellow of turmeric brown, and the blue of violet green: when excess of tartaric acid is added to it, it yields a white granular precipitate of bitartrate of potassa, and an alcoholic solution of carbazotic acid yields with it yellow and difficultly soluble crystals of carbazotate of potassa. When potassa is in combination, as, for instance, when any of its salts are dissolved in water, they are best detected by a strong solution of chloride of platinum, which causes a yellow precipitate of the potassio-chloride of platinum.

When potassium and sulphur are heated together, they combine and form a sulphuret of potassium. With the acids, potassa forms a variety of useful salts; such as nitre, or nitrate of potassa, with nitric acid; sulphate of potassa, with the sulphuric acid; and carbonate of potassa, with the carbonic acid. The latter is a very important salt: it forms great part of the residuum or ash of burnt wood, from which it is obtained by lixiviation, and brought to this country from Russia and America, under the name of *pearlash* and *potash*. It consists of 48 potassa + 22 carbonic acid; it is deliquescent, uncrystallizable, and has an alkaline reaction. When carbonic acid is passed through a solution of this salt, it becomes converted into bicarbonate of potassa, composed of 48 potassa + 44 carbonic acid. Potassium burns with great splendour in chlorine, and forms chloride of potassium; it also combines with iodine, bromine, and fluorine.

POTA'TOES. The common name for the roots of the *Solanum tuberosum*, which see.

POTE'NTIAL MOOD. (Lat. possum, *I am able*.) In Grammar, that mood of the verb which expresses an action conceived as *possible*; denoted in English by the auxiliary verb *may* or *might*.

POTE'NTIAL QUALITIES. In Scholastic Philosophy, such as are supposed to exist in a body *in potentia* only. In Grammar, a mood of the verb, also called the optative; by some considered as the same with the subjunctive.

POTI'TII. The Roman priests of Hercules, who were said to have been instituted by Evander. Of an inferior grade to them, but in the service of the same god, were the Pinari; but these became extinct through the means of Appius Claudius.

PO'TSTONE. A tough variety of steatite, sometimes manufactured into culinary vessels. It is the *lapis ollaris* of Pliny.

PO'TTERY AND PORCELAIN. The better kind of pottery, called in this country *Staffordshire ware*, is made of an artificial mixture of alumina and silica; the former obtained in the form of a fine clay, from Devonshire chiefly; and the latter consisting of chert or flint, which is heated red-hot, quenched in water, and then reduced to powder. Each material, carefully powdered and sifted, is diffused through water, mixed by measure, and brought to a due consistency by evaporation: it is then highly plastic, and formed upon the potter's wheel and lathe into various circular vessels, or moulded into other forms, which, after having been dried in a warm room, are enclosed in baked clay cases resembling bandboxes, and called *seggars*; these are ranged in the kiln so as nearly to fill it, leaving only space enough for the fuel; here the ware is kept red-hot for a considerable time, and thus brought to the state of *biscuit*. This is afterwards glazed, which is done by dipping the biscuit-ware into a tub containing a mixture of about 60 parts of litharge, 10 of clay, and 20 of ground flint, diffused in water to a creamy consistence; and when taken out enough adheres to the piece to give an uniform glazing when again heated. The pieces are then again packed up in the seggars, with small bits of pottery interposed between each, and fired in a kiln as before. The glazing mixture fuses at a very moderate heat, and gives an uniform glossy coating, which finishes the process when it is intended for common white ware.

The patterns upon ordinary porcelain, which are chiefly in blue, in consequence of the facility of applying cobalt, are generally first printed off upon paper, which is attached to the plate or other article while in the state of biscuit; the colour adheres permanently to the surface when heat is properly applied: other mineral colours, such as the oxides of chrome and manganese, are also occasionally employed in the same way.

The manufacture of Porcelain is a more refined branch of art; the materials are selected with the greatest caution, it being necessary that the compound should remain perfectly white after exposure to heat: it is also required that it should endure a very high temperature without fusing, and at the same time acquire a semivitreous texture, and a peculiar degree of translucency and toughness. These qualities are united in some of the oriental porcelain, or *China*, and in some of the old Dresden; but they are rarely found coexistent in that of modern European manufacture. Some of the French and English porcelain, especially that made at Sèvres and Worcester, is extremely white, and duly translucent; but it is more apt to crack by sudden changes of temperature; more brittle, and consequently requires to be formed into thicker and heavier vessels; and more fusible than the finest porcelains of Japan and China.

The colours employed in painting porcelain are the same metallic oxides used for colouring glass, and in all the more delicate patterns they are laid on with a camel-hair pencil, and generally previously mixed with a little oil of turpentine. Where several colours are used, they often require various temperatures for their perfection; in which case those that bear the highest heat are first applied, and subsequently those which are brought out at lower temperatures. This art of painting on porcelain, or *in enamel*, is of the most delicate description: much experience and skill are required in it, and with every care there are frequent failures; hence it is attended with considerable expense. The gilding of porcelain is generally performed by applying finely divided gold mixed with gum-water and borax; upon the application of heat the gum burns off, and the borax vitrifying upon the surface causes the gold firmly to adhere: it is afterwards burnished.

In the manufacture of various kinds of pottery employed in the chemical laboratory, and especially in regard to *crucibles*, many difficulties occur; and many requisites are necessary, which cannot be united in the same vessel. To the late Mr. Wedgwood we are indebted for vast improvements in this as well as in other branches of the art. Crucibles composed of one part of pure clay mixed with about three parts of coarse and pure sand, slowly dried and annealed, resist a very high temperature without fusion, and generally retain metallic substances; but where the metals are suffered to oxidize, there are few which do not act upon any earthen vessel, and some cause its rapid fusion, as the oxides of lead, bismuth, &c. Where saline fluxes are used, the best crucibles will always suffer; but platinum may often be employed in these cases, and the chemist is thus enabled to combat many difficulties which were nearly insurmountable before this metal was thus applied. Whenever silica and alumina are blended, as in the mixture of clay and sand, the compound softens, and the vessel loses its shape when exposed to a long-continued white heat, and this is the case with the *Hessian* crucibles: consequently, the most refractory of all vessels are those made entirely of clay, coarsely powdered burned clay being used as a substitute for the sand. Such a compound resists the action of saline fluxes longer than any other, and is therefore used for the pots in glass furnaces. A Hessian crucible lined with purer clay is rendered much more retentive; and a thin china cup, or other dense porcelain, resists the action of saline matters in fusion for a considerable time. Plumbago is a very good material for crucibles, and applicable to many purposes; when mixed with clay it forms a very difficultly fusible compound, and is protected from the action of the air at high temperatures: it is well calculated for small table furnaces.

POULP. The English generic name of the eight-footed Dibranchiate Cephalopods (*Octopi*), which have a double alternate row of suckers on each foot.

PO'ULTRY. Different kinds of birds reared for the production of eggs, feathers, and for the use of their bodies as animal food. The domestic poultry in common use in Britain are the common domestic fowls, or cock and hen, the turkey, the duck, and the goose; to which may be added, as occasionally reared, the guinea fowl and the peacock. The most generally useful kind of poultry is the common domestic fowl, which, though a native of India, accompanies man through all climates, but which is only productive of abundance of eggs when well fed and warmly lodged. Hence, all poultry houses, when not built adjoining an apartment in which fire is kept, or over a stable or cowhouse, where they might benefit by the heat generated by the larger animals, ought to be furnished with flues, or some other means of generating heat artificially during winter and spring. Without some mode of effecting this, poultry will seldom produce abundance of eggs in cold weather, particularly in the colder parts of Britain. Hence, in Scotland, the common hen roosts in the same room that the cottager lives in; and the poultry-house of the small farmer is a loft either over his kitchen, or over his cowhouse. In the management of poultry it is not sufficient to supply abundance of food and warmth, but it is equally necessary that they have ample space for exercise. This space should always contain living plants of various kinds, and some gravelly or sandy soil; because worms, snails, and insects, as well as occasionally grass and herbage, form a part of the food of poultry; and sand or gravel is swallowed by them for the purpose of promoting digestion. Hence, no healthy poultry can ever be reared in towns, however much the natural food may be imitated by the supply of animal matters, herbage, and sand: the want of exercise in poultry so circumstanced will soon become evident from the appearance of the fowls, and from the soft shell of their eggs, in consequence of the animal functions not being efficiently performed.

POULTRY-HOUSES. Structures in which poultry are kept in the night time; the principal features of which ought to be, that each kind of bird shall be separately lodged, and that all shall have access to an ample field, containing a pond and a heap of gravel. *See* POULTRY.

POUNCE. A powder to prevent ink from spreading upon paper after erasures: it is either sandarach (resin of the juniper) in powder, or the powdered bone of the cuttle-fish. The term pounce is also applied to coloured powders used by pattern drawers for sprinkling over pricked papers.

POUND. (Lat. pondus, *weight*.) A measure of weight. In England two different pounds are used; the *pound avoirdupois*, and the *pound troy*. The pound avoirdupois weighs 7000 grains troy, and the pound troy 5760 grains. The former is divided into 16 ounces, and the latter into 12. (*See* WEIGHT.) Pound is also a denomination of money; the pound sterling being equal in value to 20 shillings, or 240 pence. Anciently 240 pence were equivalent to a pound of silver; hence the origin of the term.

POUPART'S LIGAMENT. The tendinous attachment of the external oblique muscle of the abdomen to the superior and anterior spinous process of the os ileum and os pubis.

POU'RPRESTURE, or PU'RPRESTURE, in Law, is said to be when any man takes unto himself or appropriates any thing that he ought not, whether it be in any jurisdiction, land, or franchise; and generally when any thing is done to the nuisance of the king's tenants, by way of nuisance or hurt to the king's highways or demesnes, by inclosing, &c. Pourpresture may also be by tenant against lord of the fee, or by one neighbour against another.

POURSUIVANT. *See* PURSUIVANT.

POWER, in Algebra and Arithmetic, denotes the product arising from the continued multiplication of a quantity or number into itself. The successive powers of a number are formed and indicated as follows: — Thus, taking the number 3,

$$\begin{aligned} 3^1 &= 3, \text{ the 1st power of 3;} \\ 3 \times 3 \text{ or } 3^2 &= 9, \text{ the 2d power, or square of 3;} \\ 3^2 \times 3 \text{ or } 3^3 &= 27, \text{ the 3d power, or cube of 3;} \\ 3^3 \times 3 \text{ or } 3^4 &= 81, \text{ the 4th power of 3, \&c.} \end{aligned}$$

In like manner, the successive powers of the quantity a are a^1, a^2, a^3, a^4, &c. The numbers indicating the powers are called the *exponents*; and it is obvious from their formation that powers of the same quantity are multiplied by adding their exponents, and divided by subtracting their exponents. Powers are considered as negative or fractional which have negative or fractional exponents.

POWER, in Mechanics, denotes a force which being applied to a machine tends to produce motion. A *mechanical power* denotes one of the six simple machines; viz. the *lever*, the *inclined plane*, the *screw*, the *wheel and axle*, the *wedge*, and the *pulley*.

POWER. In Law, a term commonly employed to designate a reservation made in a conveyance, either for the party conveying or for some other party, to enable him to do certain acts regarding the property conveyed. Powers are either common law authorities, or have their validity from the Statute of Uses. To the former class belong powers granted by will or by act of parliament to certain persons to sell estates, &c. The latter are of several sorts — 1. Powers appendant, or appurtenant, are powers granted to one who has an estate given him by the deed creating the power, and strictly depending on he estate so limited; as where an estate for life is limited to a man, with power to grant leases in possession. 2. A power collateral, or in gross, given also to one having an interest, either granted by the same deed, or subsisting previously to its execution; but it enables him to create such interests only as will not attach on the interest limited to him, as a power to tenant for life to appoint the estate after his decease among his children. 3. A power simply collateral is one given to a party who has not any interest in the land, either after, or subsisting immediately up to, the period of the execution of the deed.

POWER OF ATTORNEY. In Law, an instrument by which a party empowers another to perform certain acts for him, either generally, or for a particular purpose; such as to accept and negotiate letters of exchange, to receive dividends, &c. An instrument by which a party authorizes his attorney to appear and plead for him is termed a warrant of attorney (see that article).

POWERS, GREAT, OF EUROPE. In the language of modern diplomacy, England, France, Austria, Russia, and Prussia, are so called.

POZZUOLA'NA. Volcanic ashes used in the manufacture of a mortar which hardens under water. They are exported from Pozzuoli, a town in the Bay of Naples.

PRAAM. A sort of lighter used in Holland and the Baltic.

PRA'CTICE. A rule in arithmetic for expeditiously solving questions in proportion; or, rather, for abridging the operation of multiplying quantities expressed in different denominations: as pounds, shillings, and pence; yards, feet, and inches, &c.

PRÆ-A'DAMITES. A term given to those inhabitants of the earth who are presumed, by some writers, to have lived before Adam. In support of this theory, a work was published in 1655, by Isaac de la Pyreri, which proved the means of converting many to its author's opinions.

PRÆCORDIA. (Lat. præ, *before*, and cor, *the heart.*) The fore part of the chest.

PRÆFECT. (Lat. præfectus.) A common name of various Roman functionaries; among others a military officer, who had the command of the cavalry of a legion. The prætorian præfect was the commanding officer of the prætorian cohorts, who were the imperial guard, and always stationed at Rome. This office, after the time of Severus, engrossed the highest powers to which a subject could attain. (*See* PRÆTORIAN COHORTS.) Præfect was likewise the title given to the imperial governor of Egypt, which was on a different footing from the other provinces, which were superintended by senatorial men with the titles of proconsul and proprætor. The præfect of Egypt, on the contrary, was always of the equestrian order, and was a military governor. This anomaly is said to have arisen from a prophecy which foretold that Egypt should recover its liberty when the Roman fasces and prætexta should come to it; and which Augustus took advantage of, to bring that province more immediately under his own superintendence.

PRÆMUNI'RE. In Law, a name given to a species of offence, in the nature of a contempt, against the king and his government. The name is derived from the words "præmoneri," or "præmuniri facias," which are used in the beginning of the writ preparatory to the prosecution of the offence: "Cause A. B. to be forewarned that he appear before us," &c. The first statute of præmunire was passed in the reign of Edward I. to restrain the encroachments of the Romish clergy; and several subsequent statutes before the Reformation have extended the number of penal acts under this title. The principal were those proceeding from an assumption of authority in England by virtue of papal and other foreign provisions. But, by still later statutes, acts of a very miscellaneous character have been rendered liable to the penalties of præmunire, as refusing to take the oaths of allegiance and supremacy, &c.

PRÆNO'MEN. *See* COGNOMEN, NAME.

PRÆTE'XTA. (Lat.) A long white robe with a purple border, originally appropriated by Tullus Hostilius to the Roman magistrates and some of the priests; but afterwards worn by the children of the higher classes; by boys till the age of seventeen (when they assumed the toga virilis), and by girls till they were married.

PRÆ'TOR. A Roman magistrate ranking in dignity next to the consuls. Anciently the name of prætor was common to all the chief magistrates; but, on account of the continual absence of the consuls in foreign wars, and their consequent inability to discharge many of their civil duties, a new civil magistrate was created to supply their place (A.U. 389), to whom the title of prætor was specially assigned. He was at first elected from the patricians, but the office was afterwards (A.U. 418) thrown open also to the plebeians. When it was found that a single prætor was inadequate to the due discharge of his duties, in consequence of the great influx of strangers, another was added (A.U. 519) to administer justice in cases in which they were involved, with the epithet *peregrinus* attached to his title, to distinguish him from the more ancient and honourable magistrate, the *prætor urbanus*, as he was called. This latter dignitary corresponded in many respects to the lord mayors, mayors, or provosts of our country, combining with their functions the judicial power of lord chancellor. Besides this he performed the duties of the consuls on many occasions in their absence, presiding in the assemblies of the people, and convening the senate. So long as the Roman empire was confined to Italy, the number of prætors did not exceed two; but on the reduction of Sicily and Sardinia to the form of provinces, two more were added to govern them, and again two more were created on the subjection of hither and farther Spain to the Roman yoke. The prætors on being elected determined their province, like the consuls, by casting lots. Under the emperors the powers of the prætors were reduced, their principal functions being transferred to the prætorian præfect; but the name of the magistrate continued to the time of Justinian. (See *Niebuhr's Roman History.*)

PRÆTO'RIAN COHORTS. A body of troops among the Romans, distinguished from the rest of the army by double pay and superior privileges, first instituted by Augustus, and called by that name, in imitation of the select band which attended a Roman general in battle. At their first institution they were nine in number, three being stationed at Rome, and the rest in the adjacent towns of Italy, and consisted of Italian soldiers only. Tiberius assembled them all at Rome, and placed them in a permanent camp; a measure which, while it answered the purpose of keeping the citizens in awe, proved dangerous and sometimes destructive to his successors. The emperor Severus disarmed the old guards, and established the prætorian cohorts on a new footing, increasing their number, and filling them entirely with troops draughted from the armies of the northern frontier. The command of these troops was vested in an officer called the Prætorian præfect, who, as the government gradually degenerated into a military despotism, rose from the station of simple captain of the guards not only to be the head of the army, but of the provinces, and even of the law. In every department of administration he represented the person and exercised the authority of the emperor. The prætorian bands were deprived of all their privileges by Diocletian, who replaced them by other troops, and were finally abolished by Constantine.

PRÆTO'RIUM. That part of a Roman camp in which the general's tent stood, and where he took the auspices. It was raised a few feet above the level of the rest of the camp. Of the four gates of the Roman camp, that which lay next the enemy was called the *prætorian* gate.

PRAGMA'TIC SANCTION, more correctly *Pragmatic Rescript*. A term of which the use seems to have originated in the Byzantine empire, signifying a public and solemn constitution or decree pronounced by a prince; distinguished from the simple rescript, which was a declaration of law in answer to a question propounded on behalf of an individual. In European history several important treaties are called by the name *Pragmatic Sanction*; among which the principal are, — 1. The ordinance of Charles VII. of France in 1438, which constituted the foundation of the liberties of the Gallican church. 2. Charles VI., emperor of Germany, being without male descendants, endeavoured by an instrument termed the Pragmatic Sanction to secure the succession to his female heirs; which caused the Bavarian war of succession, 1740. 3. The law of succession to the kingdom of Naples, when ceded by Charles II. of Spain, in 1759, to his third son and his posterity.

PRAIRIE. (Fr.) A term in common use for the vast plains or savannahs of the Mississippi and Missouri. *See* SAVANNAHS.

PRASE. Green quartz. The colouring matter of this mineral appears to be actinolite.

PRA'XEANS. A sect of heretics that sprung up in Asia in the second century; so called from their founder, Praxeas, an Asiatic hæresiarch. The distinguishing characteristics of this sect were their denial of plurality of persons in the godhead, and their belief that it was the Father himself who suffered on the cross. The Monarchici, Sabellians, and Patripassians adopted these sentiments.

PREA'MBLE. The commencement of a statute, which recites the intention of parliament in framing it, and is often admissible in argument to prove its meaning.

PRE'BEND. (Lat. præbenda.) The share of the estate of a cathedral or collegiate church received by a prebendary. To all such churches there are several prebendaries attached, who reside and officiate in rotation.

PRECE'DENCY. (Lat. precedo, *I go first.*) The relative rank of men and women in the etiquette of society; strictly it means the order in which they follow one another in a state procession, which it is part of the office of herald's duty to ascertain and preserve. The following are the degrees of precedency commonly recognized in England among men: — 1. The Sovereign. 2. The Prince of Wales. 3. The Queen's consort. 4. The Queen Dowager. 5. The princes of the blood according to seniority. 6. The Sovereign's uncles 7. Cousins of the Sovereign. 8. Husbands of princesses. 9. The archbishop of Canterbury. 10. The lord high chancellor. 11. The archbishop of York. 12. Lord high treasurer. 13. Lord president of the privy council. 14. Lord privy seal. 15. Lord high constable. 16. Earl marshal. 17. Lord high admiral. 18. Lord steward of the household. 19. Lord chamberlain of the household. (The last five, however, take precedence only of all their degree: *i. e.* if dukes, they precede all dukes; if marquises, all marquises, &c.) 20. Dukes. 21. Marquises. 22. Dukes' eldest sons. 23. Earls. 24. Marquises' eldest sons. 25. Dukes' younger sons. 26. Viscounts. 27. Earls' eldest sons. 28. Marquises' younger sons. 29, 30, 31. The bishops of London, Durham, and Winchester. 32. Other bishops, according to priority of consecration. 33. Barons. 34. Speaker of the House of Commons. 35. Viscounts' eldest sons. 36. Earls' younger sons. 37. Barons' eldest sons. 38. Knights of the Garter. 39. Privy councillors. 40. Chancellor of the Exchequer. 41. Chancellor of the duchy of Lancaster. 42. Lord chief justice of K. B. 43. Vice-chancellor. 44. Master of the Rolls. 45. Lord chief justice of C. P. 46. Lord chief baron of the Exchequer. 47. Judges and barons of the Exchequer of the degree of the coif, by seniority. 48. Knights bannerets made by the king in person. 49. Viscounts' younger sons. 50. Barons' younger sons. 51. Baronets. 52. Bannerets not made by the king in person. 53. Knights grand crosses of the Bath. 54. Knights commanders of the Bath.

55. Knights bachelors. 56. Companions of the Bath. 57. Eldest sons of the younger sons of peers. 58. Baronets' eldest sons. 59. Knights of the Garter's eldest sons. 60. Bannerets' eldest sons. 61. Knights of the Bath's eldest sons. 62. Knights' eldest sons. 63. Baronets' younger sons. 64. Esquires of the King's body. 65. Gentlemen of the privy chamber. 66. Esquires of the knights of the Bath. 67. Esquires by creation. 68. Esquires by office. 69. Younger sons of knights of the Garter. 70. Younger sons of bannerets. 71. Younger sons of knights of the Bath. 72. Younger sons of knights bachelors. 73. Gentlemen entitled to bear arms.

PRE'CEDENTS, in Law, are defined authorities to be followed in courts of justice. Precedents, strictly speaking, are only binding on tribunals when they are in the shape of actual judicial decisions of the point in question. What English lawyers term an extrajudicial opinion, — *i. e.* the opinion of a judge pronounced where it was not called for to decide the issue, — can only have authority from the character of the individual judge, and not as a precedent. When the principles of equity were as yet unsettled, it was held by many that precedents were inapplicable in that branch of law; as its very name seemed to imply that each case should be governed by the judge's opinion of its individual merits. But Lord Keeper Bridgman, among others, seriously refuted this supposition; and precedents have long been of as much authority in courts of equity as in those of common law. A form of an instrument or a pleading, from which others corresponding in circumstances may be copied, is also termed a precedent.

PRECE'PTORIES. In the Middle Ages, a kind of benefices possessed by the more eminent Knights Templar, whom the grand master created and styled *Præceptores Templi;* whence the name. Of these preceptories, 16 are recorded as belonging to the Templars in England (see *Mon. Ang.*); but it is averred by some writers that these places were merely cells, subordinate to their head-quarters, the Temple in London. *See* COMMANDERY.

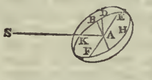
PRECE'SSION OF THE EQUINOXES. A term used in astronomy to denote a small annual variation in the position of the line in which the planes of the ecliptic and equator intersect each other, in consequence of which the sun returns to the same equinoctial point before completing his apparent revolution with respect to the fixed stars.

The longitude of a star is counted on the ecliptic eastward from the first point of Aries, or the vernal equinox. If the line of the equinoxes, therefore, maintained always the same position with respect to the celestial sphere, the longitudes of the stars would be invariable. But on comparing the actual state of the heavens with the observations recorded by ancient astronomers, it is found that the longitudes of all the stars have considerably increased, and all to the same degree; so that the celestial sphere appears to turn round the axis of the ecliptic with a slow motion from west to east, or in the same direction as the sun in his annual revolution. The phenomena, however, will be in all respects the same, if, instead of supposing the whole firmament to advance in the order of the signs, we suppose the axis of the earth's equator to have a slow motion about the axis of the ecliptic in the opposite direction. This will give to the line of intersection of the two planes (which is the line of the equinoxes) a retrograde motion from east to west, in consequence of which the sun, whose motion is from west to east, arrives at the equinoctial points sooner than if they remained at rest; and therefore the equinoxes, and the seasons which depend on them, come round before the sun has completed an entire circuit of the sphere. On this account the motion has been called the *precession of the equinoxes*.

Although the existence of the precessional motion of the equinoctial points was known at an early period in the history of astronomy, the imperfection of instruments prior to the sixteenth century did not permit of observations being made with sufficient accuracy to determine its precise rate, which must therefore be deduced from comparisons of the longitude of the same star calculated from modern observations; although, on account of the extreme slowness of the motion, the determination must be liable to some uncertainty, unless a considerable interval of time has elapsed between the epochs of observation. According to Bradley's observations, the longitude of the star *Spica Virginis*, at the beginning of the year 1760, was 200·4944°. At the beginning of 1802 Maskelyne found the longitude of the same star to be 201·0781°. The difference is 0·5837° in 42 years, which gives 50·03″ in a year. The comparison of a great number of observations on different stars gives 50·1″ for the annual precession. According to this estimate, the equinoctial points retrograde on the ecliptic at the rate of one degree in 71·6 years, and therefore will require a period of about 25,800 years to make a complete revolution.

The physical cause of the precession of the equinoxes is the combined action of the sun and moon on the mass of matter accumulated about the earth's equator, and forming the excess of the terrestrial spheroid above its inscribed sphere. The matter of this spheroidal shell, in reference to the effect of the solar attraction on it, may be regarded as forming a ring about the earth in the plane of the equator. Now the solar force, acting on the part of the ring which is above the ecliptic, may at every point be resolved into two parts, one parallel to the plane of the equator, and the other perpendicular to it; and the resultant of all the latter forces must be a force tending to impress on the ring a motion round the intersection of its plane with the ecliptic. The same thing holds true of the other half of the ring which is under the ecliptic. If the earth, therefore, had no motion of rotation, the plane of the equator would turn round the line of its intersection with the ecliptic until it coincided with the latter plane. But while the equator has this tendency to revolve about an axis in its plane, it has also a rotatory motion about an axis perpendicular to its plane; it will therefore, according to a well-known theorem in mechanics, not revolve on either of these axes, but on one which divides the angle between them, so that the sine of its angular distance from each axis is in the inverse ratio of the angular velocity round that axis. *See* ROTATION.

In order to illustrate this, let E K F H be the earth's equator, A the centre, A B the axis of rotation, S the sun, and E F the diameter of the equator perpendicular to A S; and suppose the earth to be in the position it occupies at the summer solstice. We may also



suppose the centre of gravity A to be at rest, as the effect in question is not altered by the orbital motion. It is plain that if the earth were a sphere, the sun's attraction would have no tendency to give it an angular motion about the centre A; for all the matter being symmetrically arranged about the line S A, the effect of the attraction on any point on one side of that line would be exactly compensated by the attraction on the corresponding point on the opposite side. But the earth being an oblate spheroid, we must consider the effect of the sun's attraction on the mass of matter exterior to the sphere which touches the spheroid at its poles. Now let K be an element of the protuberant matter, which we may suppose to be all accumulated in the plane of the equator; the sun's attraction on K, acting in the line which joins S and K, may be resolved into two parts, — one of them acting in the plane of the equator, and the other in a line perpendicular to that plane. The part of the solar force acting on K perpendicularly to the equator tends to give that plane a rotatory motion about the axis E F, by drawing K towards the plane of the ecliptic; but the earth at the same time revolves about the axis A B, which is perpendicular to E F. In consequence of this compound motion the axis of rotation will change its position from A B to A D, the pole B moving in a direction opposite to that of the rotation; and as the solar force continues to act at every instant, the pole B will have a continuous slow motion about the pole of the ecliptic, and the plane of the equator, which is perpendicular to A B, will at every instant intersect the ecliptic in a new line; which will slowly recede or go backward on the ecliptic in the direction opposite to that of the earth's rotation.

The motion now described may be assimilated to that of a top put into rapid motion, with its axis inclined to the horizon. In this position the axis of the top slowly revolves about the vertical drawn from the point on which it rests, describing the surface of a cone; and any section of the top perpendicular to the axis, if produced to meet the horizon, will at every instant intersect that plane in a new line; and the line of intersection will revolve with a motion corresponding to that of the axis in the direction opposite to that of the rotation.

The attraction of the moon on the spheroidal shell produces a similar effect to that of the sun, and in a still greater degree, in the ratio of about 5 to 2. It is easy to see that the effect of both those bodies in displacing the equator of the terrestrial spheroid must vary with their position in reference to it; for if they moved in the plane of the equator, there would evidently be no displacement, and their power to produce it is greatest when the earth is in such a position that the inclination of the equator to the ecliptic, or to the plane of the lunar orbit, is a maximum. This inequality of action gives rise to another highly important astronomical phenomenon; namely, an apparent vibratory motion of the equator, which Bradley (who first discovered its cause and period) significantly denominated the *nutation of the earth's axis*. *See* NUTATION.

In consequence of the precession of the equinoxes the sun's place among the zodiacal constellations, at any given season of the year, is now greatly different from what it was in remote ages. Some time before the age of Hipparchus the first points of Aries and Libra corresponded to the vernal and autumnal equinoxes, and those of Cancer and Capricorn to the summer and winter solstices,

These points have now receded 30° from the constellations to which they then corresponded. The vernal equinox now happens when the sun is in Pisces, the summer solstice when he is in Gemini, the autumnal equinox when he is in Virgo, and the winter solstice when he is in Sagittarius. Astronomers, however, still employ the term *the first point of Aries* to denote the position of the vernal equinox. On this account the *signs of the zodiac*, or ecliptic, which are fixed in respect of the equinoctial points, must be carefully distinguished from the *constellations*, which are moveable with respect to those points. (See *Airy's Mathematical Tracts; Encyc. Brit.*, art. "Precession;" *Woodhouse's Physical Astronomy;* La Place, *Mécanique Céleste;* Poisson, *Sur le Mouvement de la Terre autour de son Centre de Gravité*, in the *Mém. de l'Acad. des Sciences de Paris*, tom. vii. 1829.)

PRECI'PITATE. (Lat. præceps, *headlong.*) A result of chemical decomposition, in which a substance is *thrown down* in a solid, and generally in a finely divided state, from a liquid.

PREDA'CEANS. (Lat. præda, *booty.*) The English name used by Kirby as synonymous with the *Carnassiers* of Cuvier. *See* FERINES.

PREDESTINA'TION. (In Gr. προορισμος, Rom. viii. 29.; Eph. 1. 5. 11.) The belief that God has from all eternity decreed whatever comes to pass. In a theological sense, it is thus defined in the 17th Article of our church: — "Predestination to life is the everlasting purpose of God, whereby, before the foundations of the world were laid, he hath constantly decreed by his counsel, secret to us, to deliver from curse and damnation those whom he hath chosen in Christ out of mankind, and to bring them by Christ to everlasting salvation." The Lambeth Articles, agreed to in 1595 by a portion of the clergy, assert that "God from eternity hath predestinated certain men unto life, certain he hath reprobated." Theological writers have generally forborne to use the word predestination with respect to the rejected: "Nefas est dicere Deum aliquid nisi bonum prædestinare." (August., *De Dono Perseverantiæ.*) *See* ELECTION, CALVINISM.

PREDETERMINA'TION. In Scholastic Philosophy, that concurrence of God which determines men in the performance of their actions, good or evil; called physical predetermination, or premotion.

PRE'DIAL. (Lat. prædium, *farm.*) Of or belonging to a farm. Thus we often read of *predial* slaves and slavery, in opposition to *domestic; predial* disturbances in Ireland, &c.

PRE'DICABLE. In Logic, a term which can be affirmatively predicated of several others. The notions expressed by such terms are formed by the faculty termed abstraction, after the particular circumstances characterizing each individual have been withdrawn from it. The predicables are commonly said to be five; genus, species, difference, property (which has been subdivided into four heads by no very intelligible system of classification), and accident (which is either separable or inseparable). See these terms, and LOGIC.

PREDI'CAMENTS, or CA'TEGORIES, in Logic, are a certain number of general heads, or, in logical phraseology, *summa genera*, under one or other of which every term may be arranged. Aristotle enumerated ten predicaments; others, by subdividing some of these, have increased their number. Those of Aristotle are — substance, quantity, quality, relation, place, time, situation, possession, action, suffering. It is evident that all these may be arranged under two grand heads, — substance and attribute. *See* CATEGORY, ATTRIBUTE.

PRE'DICATE, in Logic, is, of the two terms of a proposition, that which is affirmed or denied of the other. *See* TERM, PROPOSITION, LOGIC.

PREDISPO'SING CAUSE, in Medicine, is any circumstance which renders the body susceptible of disease.

PRE-EXISTENCE. In Philosophy, the existence of any thing before another; commonly used for the existence of the human soul, in some former condition, before it became connected with its present body. It was the doctrine of the Pythagorean school, and connected with their peculiar tenet of the Metempsychosis. It was also the doctrine of Plato; and he uses in support of it arguments which have exercised a strong influence on many minds, and to this day are constantly recurring to those who study the subject on independent principles; particularly the rapidity of learning in early childhood, which he explains as an effort of reminiscence, not acquisition. Others have enlisted into the service those peculiar sensations which are sometimes raised by scenes, persons, sounds, words, though seen or heard, as our reason would persuade us, for the first time, as if we were conscious of some prior familiarity with them. This poetical, rather than philosophical view of the subject, is beautifully illustrated in a well-known ode of Wordsworth.

PRE'FACE. (Lat. præ, and fari, *to speak.*) The observations prefixed to a work or treatise, intended to inform the reader of its plan and peculiarities. There are few subjects which afford so wide a field for the display of skill and address as preface writing; and those who wish to witness an unrivalled exhibition of these qualities may consult some of Dr. Johnson's prefaces, either to his own writings, or to the numerous works which he edited.

PRE'FECT. An important political functionary in modern France. Under the old régime, the officers who were sent round to the provinces to superintend the details of administration on behalf of the king were at first styled maitres des requêtes. These were made permanent local officers in the reign of Henry II., and afterwards attained many additional powers, with the title of intendants. These were abolished at the Revolution, when various attempts were made to establish elective local governments. By a law of the year 1800 prefects were first appointed for the departments, with powers similar in many respects to those of the old intendants, with a council of the prefecture, and a general council of the department; which, however, fell into disuse. With slight variations, the prefects retain the same jurisdiction. They are, in some respects, analogous to our sheriffs; but with far greater powers. They possess not the nominal only, but the actual direction of the police establishment, within their respective departments, together with extensive powers of municipal regulation: the arrondissements or districts into which the departments are subdivided are under sous-préfets appointed by them. Their power, however, is considerably controlled by that of the council of the prefecture, which acts in some measure as a court of appeal from the prefect, taking cognizance of various cases within the sphere of his administrative interference, if legal disputes arise upon it.

PRE'HNITE. A mineral of a greenish colour, allied to the zeolites; originally discovered at the Cape of Good Hope by Colonel Prehn.

PRE'LACY. *See* EPISCOPACY.

PRE'LATE. (Lat. prelatus.) A term commonly applied to bishops, archbishops, and patriarchs, in Christian churches. Anciently, mitred abbots seem also to have been called prelates.

PRE'LUDE. (Lat. præ, *before*, and ludo, *I play.*) In Music, the preface or introduction to a movement, and usually consisting of a few bars of harmony in the same key as the movement which it precedes; being, in fact, a preparation to the ear for what is to follow.

PRE'MIER. (Fr.) The name generally given to the prime minister of England.

PRE'MISES. In Logic, the two first propositions of a syllogism are so called. *See* SYLLOGISM.

PREMO'NSTRANTS. A religious order of regular canons instituted in 1120 by St. Norbert (whence they are also called Norbertines), at Premonstratum, in Picardy, which is said to have derived its name from being *pointed out* by the Virgin. The canons of this order followed the rule of St. Austin, and were sometimes called White Canons, from the colour of their habits. They were brought into England about 1140, where they are said to have established thirty-five houses of their order.

PRENSICULA'NTIA. (Lat. prehendo, *I seize.*) A name applied by Illiger to an order of Mammalia, corresponding with the *Glires* of Linnæus and the *Rodentia* of Cuvier, and indicative of the prehensile faculty with which the fore paw is endowed in most of the species of this order.

PREPARA'TION. In Music, the previous adjustment of two notes by whose introduction a note which is to become a discord is heard in the preceding harmony. *See* MUSIC.

PREPOSI'TION. (Lat. præpono, *I place before.*) In Grammar, that part of speech which denotes the relations between objects; as *in, to, upon. See* GRAMMAR.

PRERO'GATIVE. (Lat. *prærogativa*, applied in ancient Rome to that tribe, or century, which had the privilege of giving its votes (rogare suffragia) first at the comitia.) A word in English law, signifying the king's special rights, both as chief of the kingdom in point of honour, and as supreme magistrate intrusted with the execution of the laws. Prerogatives are said to be of two kinds, direct and incidental: the first, such as belong to the king essentially by virtue of his high political character; such as the inviolability of his person, the appointment to offices and places of trust, the command of the army, the power of making war and peace, the supremacy of the national church, his legislative authority, &c.; and the latter, such exceptions as are made in his favour from the ordinary rules of law in private matters. Such are, with respect to debts, the power to levy first execution before other creditors, and of levying by the prerogative writ of extent; the power of taking goods and chattels in succession, which no other corporation can do; exemption from all customs general and special as to descent of lands, in a case where any such custom would have the effect of preventing lands held jure coronæ from passing to the successor; the abstract dominion of all lands and hereditaments by the fiction of

universal occupancy; the right to derelict lands by the sudden retiring of the sea; the dominion of seas, navigable rivers, &c.

PRERO'GATIVE COURT. The court in which wills are proved, and administrations taken, which belong to the archbishop, by his prerogative. *See* Law, Ecclesiastical.

PRESBYO'PIA. (Gr. πρεσβυς, *old*, and ωψ, *the eye*.) An imperfection of vision commonly attendant upon the more advanced periods of life, in which near objects are seen less distinctly than those at a distance. It is usually caused by flattening of the cornea; hence convex spectacles are required. It often happens that one eye is more affected than the other, in which case glasses of different foci should be used.

PRE'SBYTER. (Gr. πρεσβυτερος, *elder*; by which word it is translated in our New Testament.) One of an order of ministers in the Christian church, frequently alluded to in the Scriptures as having, in its several members, the spiritual care of distinct congregations, and exercising as a class a general superintendence over the concerns of the church. It is allowed that, up to the time of Calvin, there never existed a church in which there was not an order of presbytery, or priests, subordinate to that of bishops; and, although the words themselves are sometimes confounded in the New Testament, the assertors of episcopacy point out the distinction between the offices as accurately preserved throughout. *See* Episcopacy and Presbytery.

PRESBYTE'RIANS. The name given to that sect of Christians who have embraced the Presbyterian form of government. *See* Presbytery.

PRE'SBYTERY (Gr. πρεσβυτεριον, *a council or assembly of elders*), is that form of ecclesiastical polity according to which there is no gradation of order in the church, but which vests church government in a society of clerical and lay presbyters, or, in common phraseology, ministers and lay elders, all possessed officially of equal rank and power. The Presbyterians maintain that the words presbyter (πρεσβυτερος) and bishop (επισκοπος) are synonymous and interchangeable terms; that we nowhere read in the New Testament of bishops and presbyters or of pastors of different rank, in the same church; that all ministers of the gospel, being ambassadors of Christ, are inherently equal; and that deacons are laymen, whose sole duty it is to take charge of the poor. Among other proofs they quote the following:—"The elders (πρεσβυτεροι) who are among you I exhort, *who am also an elder* (συμπρεσβυτερος). Feed the flock which is among you, taking the oversight thereof (επισκοπουντες, *acting as bishops over them*), not by restraint, but willingly; not for filthy lucre, but of a ready mind; neither as being lords over God's heritage." (1 Peter, v. 1, 2, 3.) It is contended that, in this passage, the identity of presbyter and bishop is apparent; and that the apostle himself, as an officer of the church, was simply a presbyter or elder. (See also Hebrews, xiii. 7. 17.; 1 Thess. v. 12. 6.) On these grounds the Presbyterians assume that "the very chiefest apostles" were presbyters, or labouring ministers; and that every faithful pastor of a flock ordained by the imposition of hands, as sanctioned and taught in Scripture, is a successor of the apostles in every respect in which divinely inspired men can be regarded as having any successors. It is farther argued, in support of the polity under review, that Timothy himself, though said to be a bishop, was ordained "with the laying on of the hands of the *presbytery*." (1 Tim. iv. 14.)

It is, however, admitted by the Presbyterians that episcopacy was introduced at an early period into the Christian church, and has hitherto been the prevailing polity; but they insist that as St. Paul presided at the ordination of Timothy, not as supreme over his brethren, but as moderator or chairman for the occasion, *primus in paribus*, so the moderator of a presbytery, instead of being changed or re-elected, had in course of time been declared permanent; and hence the origin of the episcopal order. (*Mosheim*, i. 90.; *Hill's Theol. Institutes*.)

But while the Presbyterians trace the origin of their church to the practice of the apostles, and affirm that there are no intimations of episcopacy in Scripture, or in the writings of the apostolical fathers, they admit that presbytery, as it now obtains, did not exist between the 2d century and the reformation of religion. "The first reformers, who believed that the distinction between bishops and presbyters had no foundation in Scripture, and who wished to apply an effectual remedy to the abuses which appeared to them to have arisen in the progress of human inventions of investing bishops with powers superior to presbyters, did not consider the antiquity or universality of that practice as any reason for its being continued. Recurring to what they considered the primitive Scripture model, they laid the foundation of presbyterian church government on this principle, that all members are equal in rank and power; and they did not admit any official preference, but that which is constituted by voluntary agreement for the sake of order." (*Hill's Theol. Inst.* p. 167.)

The first presbyterian church, in modern times, was founded in Geneva by John Calvin, about 1541; and the system was thence introduced into Scotland, with some modifications, by John Knox, about 1560, but was not legally established there till 1592. For about a century from this date there was a continual struggle in Scotland between presbytery and episcopacy for superiority. The latter (which was patronized by the court) predominated in 1606; but was superseded by the former (to which the great body of the people were attached) in 1638. Presbytery kept its ground from this period till the revolution in 1660, when episcopacy again obtained the ascendancy, which it maintained till 1688; soon after which it was abolished, and the national church of Scotland declared presbyterian,—a form which it has since retained. The most numerous bodies of dissenters from the Scottish established church, such as the Associate and Relief Synods, are also Presbyterians; their cause of secession being that the church had relaxed the strictness of presbyterian principles.

Presbytery has never flourished greatly in England. Here the first presbyterian church was formed at Wandsworth, Surrey, in 1572, about 20 years before presbytery was established by law in Scotland; but though the system was never palatable to the English nation generally, an attempt was made to make the established church presbyterian in the reign of Charles I. This object was signally promoted by the famous Assembly of Divines at Westminster. In 1649, presbytery was sanctioned by the English parliament, and the established church was nominally presbyterian from this date till the restoration in 1660; yet it was never generally adopted, or regularly organized, except in London and in Lancashire. (*Murray's Life of Samuel Rutherford*, Edin. 1828, chap. viii.) Upwards of 2000 presbyterian clergy were ejected from their cures in England, in consequence of the Act of Uniformity in 1662. There are still many congregations (about 150) in England, particularly in the northern counties, called presbyterian; some of them in full connection with the Scottish church, others differing materially from that polity, while not a few of them have adopted nearly the same church government with the Independents. In Ireland, chiefly in the province of Ulster, there are about 450 presbyterian congregations. There are upwards of 100 such congregations in our North American possessions; and presbytery has also been introduced to a greater or less extent in the other British colonies.

In the United States of America presbytery embraces upwards of 2800 congregations, with 2000 ministers. (*American Almanac* for 1840.) The same system, though somewhat modified from that which obtains in Scotland, is the established church in Holland. (*Steven's Brief View of the Dutch Eccles. Establishment*, ed. 1839.) It still exists, though to a very limited extent, in Geneva; it prevails also less or more in several of the other Swiss cantons.

The constitution of the church of Scotland, which has long been the most perfect and efficient model of presbytery, is as follows:—The kirk session is the lowest court, and is composed of the parochial minister and of lay elders, the number of whom varies in different parishes, but is generally about 12. The minister is moderator *ex officio*. This kirk session exercises the religious discipline of the parish; but an appeal may be made from its decisions to the presbytery, the court next in dignity. The presbytery, from which there is a power of appeal to the synod, is composed of the ministers of a number of contiguous parishes (varying in number in different cases), with a lay elder from each. A moderator, who must be a clergyman, is chosen every half year. A presbytery generally meets once a month, but it must meet at least twice a year; and it may hold *pro re nata* meetings. This court takes young men on trials as candidates for licence; ordains presentees to vacant livings; has the power of sitting in judgment on the conduct of any of its members, and can depose them; and has the general superintendence of religion and education within its bounds. The number of presbyteries is at present 82. The synod, which meets twice yearly, is formed of the members, both lay and clerical, of two or more presbyteries. At every meeting a moderator is chosen, who must be a clergyman; and a sermon is preached before the court proceeds to business. The number of synods is sixteen. The general assembly is the highest ecclesiastical court, its decisions being supreme. It meets annually in the month of May, and sits for ten successive days. Unlike the inferior courts, it consist of representatives chosen by the various presbyteries, royal burghs, and universities of Scotland. The number of representatives from presbyteries depends on the number of members of which each is composed. No presbytery sends less than two ministers and one lay elder; and none more than six ministers and three elders. The total number of members of the general assembly is 386, of whom 218 are ministers. This supreme court has of late consisted of more than this number, as the church

has admitted the ministers of *quoad sacra* parishes as constituent members of ecclesiastical courts; but the civil law has not given its sanction to this measure: indeed the question is at present *sub judice*. The assembly chooses a new moderator yearly, who, in recent times, is always a clergyman. A sermon is preached before the opening of the court. The assembly is honoured with the presence of a nobleman as representative of the sovereign, under the title of lord high commissioner; but this high functionary takes no part in the proceedings of the court, except in opening and closing or dissolving its sittings, and has no voice in its deliberations. The assembly before its close appoints a commission, which is equivalent to a committee of the whole house, being composed of all the members of assembly, and one minister additional, named by the moderator. The commission meets quarterly; but may hold *pro re nata* meetings.

The income of the clergy, which may average about 250*l*. yearly, including manse and glebe, is regulated by the state; and they are nominated to livings by patronage. They have no liturgy, no altar, no instrumental music. The Scottish presbyterians do not kneel, but stand in time of prayer; and in singing the praises of God they sit. The sacrament of the Supper is not administered in private houses to any person under any circumstances whatever. (*The Directory for the Public Worship of God, by the Westminster Assembly of Divines*.) Pluralities have been prohibited; and the residence of clergymen within their repective parishes has always been imperative. Their creed is rigid Calvinism, and may be found embodied in the *Westminster Confession of Faith* and the *Larger* and *Shorter Catechisms*. But though the faith of the Scottish Presbyterians, whether churchmen or dissenters, is Calvinistic, not a few of the Presbyterians in other countries have adopted an Arminian, and not unfrequently a Unitarian creed. (*Adam's Relig. World Displayed*, ii. 289—305.; *Lord King's Inquiry into the Constitution of the Primitive Church; Forbes's Presbyterian Letters*.)

Presbytery. In the Scottish Kirk, a district composed of a number of adjacent parishes. See the preceding article.

Presbytery. In Architecture, a portion of the choir or chancel of a church arranged with seats for the dignitaries of the establishment.

PRESCRI'PTION. A title acquired by use and time to incorporeal hereditaments, such as a right of way or of common, and the like. All prescription is either personal, as when it is in a man and his ancestors, or it is in right of a particular estate; which last being in a man, and those whose estate he hath, is called prescription in a *que* estate. It presupposes a grant, and can therefore give a title to those things only which can pass by grant. After uninterrupted enjoyment for thirty, and in many cases for twenty years, a primâ facie title arises by prescription to the thing enjoyed; and unless such enjoyment have continued under some consent or agreement, the title becomes, in sixty years, absolute and indefeasible. The time of prescription in most of the ordinary instances to which it applies is now regulated by 2 & 3 W. 4. c. 71.

PRESENTATION. In Law, the appointment of a clergyman to a benefice by the patron, which takes place by presenting him to the bishop for institution.

PRESENTATION, FEAST OF. In Ecclesiastical Usage, the same with the Purification of the Blessed Virgin. *See* Purification.

PRESE'NTMENT, in Criminal Law, is defined to be an information made by the jury in a court before a judge who has authority to punish an offence. Properly speaking, it is the notice taken by a grand jury of their own knowledge, without any bill or indictment found before them, at the suit of the king, of any offence, nuisance, libel, &c. of which they are competent to take notice. An indictment, correctly speaking, is that which is drawn up and engrossed to be found by the grand jury, founded on their presentment or note of instruction. Presentment is also comprehensively taken to include inquisitions of office and indictments, as well as presentments strictly so called.

PRE'SIDENT. (Lat. præsideo, *I sit foremost*.) A title applied to many officers in various capacities, but generally denoting a pre-eminency, either temporary or fixed, among a number of individuals assembled for a definite purpose. Thus the superior of a board or council, &c. is generally entitled president, as is the individual called to preside over an occasional meeting, or to fill the chair at a club, dinner, &c.; although the old English title of chairman is frequently used on such occasions.

The supreme executive officer of the United States of America is styled president. The qualifications required of a person raised to this dignity are, to be a natural-born citizen of the age of thirty-five years, and to have resided fourteen years within the States. The election is by electoral colleges in every state. These colleges contain, in each state, a number of electors equal to all the senators and representatives of that state in congress; but their appointment varies in different states, and at different times; sometimes it is made by their respective legislatures, sometimes by general election throughout the state, sometimes part of the electors are chosen by district and part by general election. The colleges in each state vote by ballot for a president (and at the same time for a vice-president); and the votes of all the electors, taken in this manner, are counted by the president of the senate: when, if any person have an absolute majority of votes, he is duly elected; if not, the election is made by the house of representatives between the three persons having the highest number; in which case the votes are taken by states, and a majority of all the states is necessary to constitute a choice. On two occasions, of which the last was in 1824, no candidate having had a majority of the whole number of voters, the house of representatives has proceeded to make the election; and, on the last of these occasions, a majority of states chose a candidate (Adams) who had a smaller number of electoral votes than one of his opponents (Jackson). On one occasion, in 1800, the states balloted thirty-six times before any candidate could obtain an absolute majority. Should the president die during his term of office, he is succeeded by the vice-president, an event which has recently occurred.

In his legislative capacity, the president has the power of approving bills sent to him after passing both houses of congress, or of returning them to the house in which they have originated with his objections annexed. In the latter case, the bill must be reconsidered by that house; and if, on reconsideration, it obtain a majority of two thirds in both houses, it passes into a law. In his executive capacity, he is commander-in-chief of the army and navy of the Union, and of the state militias when called into the service of the Union; he has the power of reprieving and pardoning, except in cases of impeachment; he has power to make treaties, with the consent of the senate (by a majority of two thirds); he nominates ambassadors, consuls, judges of the supreme court, and all other officers of the United States whose appointments are not vested elsewhere by the constitution.

PRESIDENT, LORD, OF THE COUNCIL. The fourth great officer of state in England; appointed by letters patent under the great seal, durante bene placito.

PRESS. (Fr. presse.) The machine by which books, &c. are printed. Very little improvement in the construction of this instrument took place from the first introduction of the art into Europe till the late Earl Stanhope applied the powers of his mind to the subject, and introduced a new press of a decidedly superior construction. The old press was made of wood, with an iron screw that had a bar fitted in it; to the lower end of this screw was attached, horizontally, a flat piece of wood, called the platen, which was brought down by means of the screw, and pressed the paper upon the face of the types; and thus the impression was obtained. This press has, however, entirely given place to presses made of iron. Lord Stanhope's press is constructed of iron, with a screw; but the bar is fixed to an upright spindle, to which a lever is attached connected with a second lever fixed to the top of the screw by a connecting bar. These two levers are placed at different angles to each other; and when the platen is brought down to the face of the types, and power is wanted, the two levers take such a position with each other so as to act with the greatest advantage, and thus an almost incredible accession of power is gained, which enables the pressman to print larger sheets of paper in a superior manner, with less labour, and with greater ease to himself. This press maintains its superiority over all others.

This great improvement in the printing press that Lord Stanhope had accomplished excited other ingenious men to exert their abilities in attempts at further improvements; among whom was a Mr. George Clymer, an American, who brought forward an iron press, called the Columbian press, in which he discarded the screw, and obtained his power entirely by levers. This press has great power, and consequently great strength, and is made of a size to print larger sheets of paper than any other; but for the common run of printing it does not work so easy as the Stanhope press. These two are looked upon as the best presses.

There are a variety of others which are great improvements upon the old construction, and which are held in estimation by printers, but the limits of this work will not admit of the details of their respective merits.

The *book press*, in the warehouse department, used for pressing books previous to their delivery, is the common screw press, with a perpendicular screw, and screwed down by means of an iron bar: it is also used for pressing paper, when wetted, previous to being printed on, for the purpose of making it in better condition for the process; and also in cylindrical or machine printing to cause it to lie flat, otherwise it is apt to wrinkle, particularly large sheets, in being carried round the cylinders upon a flat surface. In large establishments Brahmah's hydraulic

press is generally used for these purposes, as being much more powerful, and also more expeditious, not only in its use, but also in its effect.

PRESS. A machine for the purpose of compressing or squeezing bodies. Any of the mechanical powers may be used for this purpose. When constructed on a large scale, the hydrostatic pressure of water is the power generally employed. *See* HYDROSTATICS.

PRESS is metaphorically applied either to the whole literature of a country, or to that part of it more immediately connected with newspapers or other periodical publications.

PRESSIRO'STERS, *Pressirostres.* (Lat. pressus, *flattened;* rostrum, *a beak.*) A tribe of wading birds, including those which have a flattened or compressed beak.

PRE'SSURE. Dr. Young defines pressure to be "a force counteracted by another force, so that no motion is produced." (*Lectures on Nat. Phil.*) Thus, when a heavy body is supported on a table, or the ground, the force of terrestrial gravity, which, if the support were removed, would cause the body to descend towards the centre of the earth, being destroyed at every instant by the resistance of the support, produces a pressure. A pressure and a moving force differ from one another only in this respect, that the infinitely small velocities which the pressure tends to produce are incessantly destroyed by the resistance of the obstacle; whereas those that are actually produced at every instant by the moving forces are accumulated in the moving body, and produce a finite velocity after a finite time. The pressures of two different bodies are, therefore, to each other as the masses multiplied by the infinitely small velocities which they tend to produce in the same instant of time, and which they would produce if the bodies were free to move.

The pressure of a solid body is exerted in the direction of the resultant of all the forces by which the body is acted upon. In the interior of liquid and aëriform bodies, the pressure is equal in all directions. (*See* HYDROSTATICS, PNEUMATICS.) *Centre of Pressure*, in Hydrostatics, is that point of a plane or side of a vessel containing a liquid to which, if a force were applied equal to the total pressure, and with the opposite direction, it would exactly balance the effort of the total pressure.

PRESSWORK, in Printing, is the operation of taking impressions from types, &c. by means of the press; distinct from *composing*, which is arranging the types to prepare them for press.

PRESTO. (It.) In Music. *See* ALLEGRO.

PRESU'MPTION OF LAW, is the assuming the truth of a certain state of facts by the ordinary custom of the law. It is either "juris et de jure," which is a presumption which no evidence to the contrary can be admitted to traverse, as the presumption of incapacity in a minor with guardians to act without their consent; or it is "juris" only, which may be traversed by evidence, as where the property of goods is presumed to be in the possessor until the contrary is shown.

PRESUMPTIVE HEIR. *See* HEIR.

PRETE'NDER. The name by which the Chevalier Charles Stuart is usually known, from his having pretended a right to the British crown, from which he had been excluded.

PRE'VOTALES, COURS. (Fr. *courts of prevots, or provosts.*) Certain tribunals of summary jurisdiction, which existed in France before the Revolution, were called by this name. They were the courts of the prevots of France and of Paris, of the prevots des maréchaux (*see* PROVOST, PROVOST-MARSHAL, &c.), and exercised a summary jurisdiction over vagrants, highway robbers, disturbers of the peace, &c. These ancient institutions furnished Napoleon with the model of certain extraordinary courts, with mixed civil and military judges, which were formed in 1808 for the purpose of preserving public order in a summary manner. All these unconstitutional tribunals were abolished by the first charter of 1814; but with provision for the restoration of the Cours Prevotales, should it be thought necessary. They were accordingly established in 1815, to last for two years; but expired in 1818.

PRIA'PUS. (Gr. Πρίαπος.) A divinity introduced into Grecian mythology after the time of Alexander. He was the god of fruitfulness, and by the Romans was looked on particularly as the guardian of gardens, in which indecent and rudely sculptured wooden statues of him were usually set up.

PRICE (Fr. prix), in Commerce, means the value or exchangeable worth of any commodity or product estimated or rated in money, or simply the quantity of money for which it will exchange. The price of a commodity rises when it fetches more, and falls when it fetches less money.

Price of freely produced Commodities. — The exchangeable value of commodities — that is, their power of exchanging for or buying other commodities — depends, at any given period, partly on the comparative facility of their production, and partly on the relation of the supply and demand. If any two or more commodities respectively required the same outlay of capital and labour to bring them to market, and if the supply of each were adjusted exactly according to the effectual demand — that is, were they all in sufficient abundance, and no more, to supply the wants of those able and willing to pay the outlay upon them, and the ordinary rate of profit at the time, they would each fetch the same price, or exchange for the same quantity of money or any thing else. But if any single commodity should happen to require less or more capital and labour for its production, while the quantity required to produce the others continued stationary, its value, as compared with these, would, in the first case, fall, and in the second rise; and supposing the cost of its production not to vary, its value might be increased by a falling off in the supply, or by an increase of demand, and conversely.

But it is of importance to bear in mind, that all variations of price arising from any disproportion in the supply and demand of such commodities as may be *freely produced in indefinite quantities* are *temporary* only; while those that are occasioned by changes in the cost of their production are *permanent*, at least as much so as the cause in which they originate. A general mourning occasions a transient rise in the price of black cloth; but supposing that the fashion of wearing black were to continue, its price would not permanently vary; for those who previously manufactured blue and brown cloths, &c., would henceforth manufacture only black cloth; and the supply being in this way increased to the same extent as the demand, the price would settle at its old level. Hence the importance of distinguishing between a variation of price originating in a change of fashion, or other accidental circumstance — such, for example, as a deficient harvest, — and a variation occasioned by some change in the cost of production. In the former case, prices will at no distant period revert to their old level; in the latter, the variation will be lasting.

When the *price* of a freely produced commodity rises or falls, such variation may evidently be occasioned either by something affecting its value, or by something affecting the value of money; but when the generality of commodities rise or fall, the fair presumption is, that the change is not in them, but in the money with which they are compared. This conclusion does not, however, apply in all cases; and we believe that most part of that fall in the price of commodities which has taken place since the peace, and which has been so generally ascribed to a rise in the value of money occasioned by a decline in the productiveness of the mines, has been caused by the increased productiveness of industry, arising from the abolition of oppressive restraints on commerce, the opening of new and more abundant sources of supply, and the discovery of new means and improved methods of production.

Price of monopolised Commodities. — Exclusive, however, of the commodities now alluded to, there is a considerable class whose producers or holders enjoy either an *absolute* or a *partial* monopoly of the supply. When such is the case, prices depend entirely or principally on the proportion between the supply and demand, and are not liable to be influenced, or only in a secondary degree, by changes in the cost of production. Antique statues and gems, the pictures of the great masters, wines of a peculiar flavour produced in small quantities in particular situations, and a few other articles, exist under what may be called absolute monopolies; — their supply cannot be increased; and their price must therefore depend entirely on the competition of those who may wish to buy them, without being in the slightest degree influenced by the cost of their production.

Monopolies are sometimes established by law; as when the power to supply the market with a particular article is made over to one individual or society of individuals, without any limitation of the price at which it may be sold; which of course enables those possessed of the monopoly to exact the highest price for it that the competition of the buyers will afford, though such price may exceed the cost of production in any conceivable degree. Monopolies of this sort used to be common in England, particularly in the reign of Elizabeth; but they were finally abolished by the famous act of the 21 Jac. 1. c. 3., an act which, by establishing the freedom of competition in all businesses carried on at home, has been productive of the greatest advantages.

The rights conveyed by patents sometimes establish a valuable monopoly; for they enable the inventors of improved methods of production to maintain, during the continuance of the patent, the price of the article at a level which may be much higher than is required to afford them the ordinary rate of profit. This advantage, however, by stimulating invention, and exciting to new discoveries, of which it is the natural and appropriate reward, instead of being injurious, is beneficial to the public.

There are also partial monopolies, depending upon situation, connection, fashion, &c.; these and other inappreciable circumstances sometimes occasion a dif-

ference of 30 per cent., or more, in the price of the same article in shops not very distant from each other.

Generally speaking, the supply of monopolised commodities is less liable to vary than those that are freely produced; and their prices are commonly steady. But there are various exceptions to this rule; and of these the partial monopoly of the supply of corn, which the existing corn laws secure to the British agriculturists, may be taken as an example. The variations in the harvests of particular countries, and their average equality throughout the world, expose a nation which shuts foreign corn out of its ports to vicissitudes of price, from which it would enjoy a comparative exemption were its ports always open. Sometimes the expiration of a monopoly, a patent for example, has occasioned a sudden and extraordinary increase of supply, and consequent fall of price; entailing, of course, a serious loss on the holders of large stocks of goods produced under the monopoly.

New Sources of Supply. — The effects on prices produced by the opening of new markets, or new sources of supply, are familiar to every one. The fall that has taken place in the price of pepper, and of most sorts of commodities brought from the East, since the opening of the trade in 1814, is a conspicuous proof of what is now stated.

Influence of Taxes on Prices. — It is unnecessary to dilate on a topic so familiar to every one. When a tax is laid on a commodity, its price necessarily rises in a corresponding proportion; for otherwise the producers would not obtain the ordinary rate of profit, and would, of course, withdraw from the business. A considerable part of the price of many articles in this and other countries really consists of the tax or duty laid upon them.

These statements will probably suffice to give our readers a general idea of the principles which determine the value of commodities. To go deeper into the subject would involve us in discussions that belong to political economy, and which are nowise suited for such a work as this.

Such however of our readers as wish for full and satisfactory information as to these topics, and the practical operation of the different circumstances to which we have now adverted, would do well to consult Mr. Tooke's *History of Prices*. This work is especially valuable for the rare union which it exhibits of a perfect knowledge of principles with the most extensive acquaintance with practical details.

PRICKING-UP. In Architecture, the first coating of plaster in work of three coats upon laths. It is executed with *coarse stuff* in London, usually compounded with road stuff, or Thames sand. The surface is scratched over, to form a better key for the next coat.

PRICK-POST. In Architecture, a post in wooden buildings framed intermediately between two principal posts.

PRIEST. (Gr. πρεσβύτερος, *elder.*) Etymologically, the Christian priest is merely a minister who presides over the spiritual affairs of a congregation. The word, however, is commonly used also to represent the Greek ἱερεύς, who, like the Jewish priest, had both a sacrificial and mediatorial character; and the Roman Catholic looks upon the Christian priest in the same light.

PRIMÆ VIÆ. (Lat. *the first passages.*) Medical men apply this term to the stomach and bowels.

PRI'MAGE. A certain allowance paid by the shipper or consigner of goods to the master and sailors of a vessel for loading the same. It varies in different places according to their respective customs.

PRI'MARY COLOURS. The colours into which a ray of white solar light may be decomposed or separated. Newton supposed them to be seven; red, orange, yellow, green, blue, indigo, and violet. Mayer considered some of these to be secondary colours, and that there are only three primary colours in the solar spectrum; namely, red, yellow, and blue, certain portions of which constitute white light and all the other colours. (*Opera inedita*, 1775.) Dr. Young assumes red, green, and violet as the fundamental colours. (*Lectures on Nat. Phil.* p. 439.) In fact, any three prismatic rays may be assumed as the primary colours, and all the rest compounded from them, provided we attend only to the predominant tint resulting, and disregard its dilution with white. (*Herschel on Light*, § 518.) *See* CHROMATICS, LIGHT.

PRIMARY ROCKS, or PRIMITIVE ROCKS. *See* GEOLOGY.

PRI'MATE. (Lat. primus, *first.*) A prelate of superior dignity and authority. In England, the archbishop of York is entitled Primate of England; the archbishop of Canterbury, Primate of all England.

PRIMA'TES. The name given by Linnæus to the first order of animals in his *Systema Naturæ*, which associated man with the monkeys and bats, and corresponded to the Bimana, Quadrumana, and Cheiroptera of Cuvier.

PRIME NUMBERS, in Arithmetic, are numbers which have no divisors, or which cannot be divided into any less number of equal integral parts than the number of units of which they are composed; such are 2, 3, 5, 7, 11, 13, &c.

A general method of finding prime numbers, beyond a certain limit, by a direct process, is one of the most difficult problems in the theory of numbers; and, though often sought after, has not yet been discovered. Many remarkable properties of numbers have, however, been detected, by means of which it is in most cases not difficult to determine whether an assigned number is prime or not. Some of these properties are the following: —

1. Every prime number above 3 is comprehended in one of these forms, $6n+1$, or $6n-1$ (n being any whole number); that is to say, if a prime number be increased or diminished by unity, the result is a multiple of 6. In order to prove this, it will be sufficient to remark that every whole number is necessarily comprised in one or other of these six forms (where n is successively 0, 1, 2, 3, &c.),

$$6n+1,\ 6n+2,\ 6n+3,\ 6n+4,\ 6n+5,\ 6n+6.$$

Now the second, fourth, and sixth of these forms, being divisible by 2, cannot give prime numbers. The third gives only numbers divisible by 3; therefore the primes can only be of the form $6n+1$, or $6n+5$. But $6n+5 = 6n+6-1 = 6(n+1)-1 = 6n'-1$, n' being any whole number; it follows therefore that all prime numbers are comprehended in one of the forms $6n+1$, or $6n-1$.

2. In like manner, every prime number above 2 is of one of the forms $4n+1$, or $4n-1$; and every prime number, excepting 2, of one of the forms $8n+1$, $8n+3$, $8n+5$, $8n+7$. In fact, prime numbers may be divided in this manner into classes, according to any modulus, at pleasure; the last four forms, however, are those which possess the most distinctive properties.

Although every prime number is comprehended in one of these forms, the converse proposition is not true; namely, that every number in one of these forms is a prime number. No direct rule has yet been given by which it can be determined *à priori* whether a given number be prime or not.

3. If a number cannot be divided by another number less than the square root of itself, that number is a prime.

4. If n denote any prime number, the product, $1\cdot2\cdot3\cdot4\cdots(n-1)$, increased by unity, is divisible by n.

It is frequently of use in arithmetical investigations to know whether a number is prime or not; tables of them have accordingly been formed to a certain extent, and are given in various works. Vega's tables contain the prime numbers under 400,000. The largest prime number which has yet been verified is $2^{31}-1=2147483647$. This was found by Euler.

For properties of prime numbers, see Fermat's edition of *Diophantus; Euler's Algebra*, and *Analysis Infinitorum;* Legendre, *Essai sur la Théorie des Nombres; Barlow's Elementary Investigations, &c.;* and especially the *Disquisitiones Arithmeticæ* of Gauss, of which there is a French translation by Delisle.

Prime and Ultimate Ratios.—A method of calculation invented by Newton, and employed in the *Principia*, being an extension and simplification of the ancient method of exhaustions. It may be thus explained: — Let there be two variable quantities constantly approaching each other in value, so that their ratio or quotient continually approaches to unity, and at last differs from unity by less than any assignable quantity; the *ultimate ratio* of these two quantities, is said to be a ratio of equality. In general, when different variable quantities respectively and simultaneously approach other quantities considered as invariable, so that the differences between the variable and invariable quantities become at the same time less than any assignable quantity, the ultimate ratios of the variables are the ratios of the invariable quantities or *limits*, to which they continually and simultaneously approach. They are called *prime ratios*, or *ultimate ratios*, according as the ratios of the variables are considered as receding from, or approaching to, the ratios of the limits. (See *Principia*, book i.)

PRI'MER, signified anciently a religious work employed in the Roman Catholic service; but it is now generally used to denote the first book for children.

PRIMER SEISIN. (Norm. Fr.) An ancient branch of the royal prerogative in England, whereby it had possession for a year of the lands and tenements of which a tenant in capite died seised, if the heir was of full age; or, if not, until he was of age.

PRIME VERTICAL. In Astronomy, the vertical circle of the sphere which intersects the meridian at right angles, and passes through the east and west points of the horizon. In dialling, prime vertical dials are those which are projected on the plane of the prime vertical, or a plane parallel to it.

PRI'MINE. In Botany, the outermost sac or covering of an ovule; either composed of cellular tissue only, or traversed by numerous veins or bundles of tubes.

PRIMING. (Lat. primus, *first.*) In Architecture, the first coat of painting.

PRIMIPI'LUS. In Ancient History, the name of the centurion of the first cohort of a legion, who had charge of the Roman eagle. This office was one of considerable dignity, and entitled its holder to various privileges, which conferred both rank and emolument. On quitting his charge, the primipilus assumed his place among the members of the equestrian order, with the title primipilarius. (See *Adam's Rom. Antiquities; Mém. de l'Acad. des Inscr.* vol. xxxii.)

PRIMI'TIÆ. The first fruits of any production of the earth, which were uniformly consecrated to the Deity by all the nations of antiquity. *See* FIRST FRUITS.

PRI'MITIVE. In Grammar, a word neither derived from any other language, nor compounded from any other words of the same; as *horse*, *man*.

PRI'MITIVE COLOURS, in Painting, are red, yellow, and blue, from the mixtures whereof all other colours may be obtained.

PRIMOGE'NITURE. The right of the eldest son, and those who derive through the eldest son, to succeed to the property of the ancestor. Among ancient nations, the Jews alone appear, as far as is known, to have recognized this usage among their institutions. For some notice of the policy of the system of primogeniture, see SUCCESSION, LAW OF.

PRIMULA'CEÆ. (Primula, one of the genera.) A natural order of herbaceous Exogens, inhabiting the northern and colder parts of the globe. It is nearly allied to all the regular Monopetalous orders, with a capsular superior fruit, especially to *Solanaceæ* and *Ericaceæ*, from both of which it is readily known by the stamens being placed opposite to the segments of the corolla. In this respect it agrees with *Myrsinaceæ*, which differ chiefly in their fleshy fruit and arborescent habit. The cowslip, from which a sedative wine is made; the primrose, auricula, and the acrid cyclamen; together with anagallis, or the herb pimpernel, which regularly closes its flowers at the approach of rain, — are species of this order.

PRI'MUM MO'BILE, in the Ptolemaic Astronomy, is the outermost sphere of the universe, which gives motion to all the others (*i. e.* those of the moon, planets, &c.), and carries them round with it in its diurnal revolution. Its centre is the centre of the earth.

PRI'MURIES, or PRIMARY QUILLS. (*Primores*, Linn.) The largest feathers of the wings; they rise from the pinion-bones, or those corresponding to the metacarpus and digits.

PRINCE. (From the Latin princeps, *first*, *leader*, *or foremost.*) This title is probably of Teutonic origin: the German equivalent, fürst, has the same etymological signification, and the Latin nation appears to have translated it. In England, the title is applied only to members of the royal family; and in no case, except that of the eldest son of the reigning king (Prince of Wales), is it connected with a territorial distinction. On the Continent, the rank of princes is various: in France, under the old regime, the title belonged only to certain families of high distinction, connected with the royal blood; it ranks in Germany below that of duke.

PRINCE OF WALES. The title bestowed by patent on the heir apparent to the crown of England. He is born Duke of Cornwall, &c.; but the title of Duke of Cornwall does not necessarily belong to the heir apparent, as it can only be held by the *first-begotten* (not *eldest*) son of a king: thus Henry VIII. was not, in the life of his father, Duke of Cornwall. The origin of the title of Prince of Wales is as follows: — When Edward I. subdued Wales, he promised the people of that country, upon condition of their submission, to give them a prince who was born amongst them, and who could speak no other language. Upon their acquiescence with this deceitful offer he conferred the principality of Wales upon his second son Edward, then an infant, born within the principality, and unable to speak any language. Edward, by the death of his elder brother Alfonso, became heir to the crown, and from that time this honour has been appropriated to the eldest sons of the Kings of England. The Earldom of Chester, which is likewise usually conferred upon the heir-apparent, was once a principality, and erected into that title by parliament in the 21st of Richard II.; it was then appointed to be given to the king's eldest son. But the whole acts of that parliament were repealed in the reign of Henry IV., although the earldom has usually been since given with the principality of Wales. The revenue of the last Prince of Wales was 125,000*l.*; 60.000*l.* being paid from the civil list, and 65,000*l.* from the consolidated fund. His income was last regulated by 35 G. 3. c. 125. To compass the death of the Prince of Wales, or violate the chastity of his consort, is high treason within the statute of 25 Ed. 3. The Prince of Wales has a household of his own, of which the chief officers are a comptroller and auditor-general, treasurer, vice-chamberlain, Gloucester king-at-arms, and herald; besides another class of officers belonging to the duchy of Cornwall, and another as great steward of Scotland. As Duke of Cornwall and Earl of Chester, the prince appoints sheriffs, &c. for those counties. By a statute of the order of the Garter, issued in 1805, the Prince of Wales was declared a constituent part of the original institution. Hence every prince becomes a Knight of the Garter the moment he is created Prince of Wales. For the constitutional question raised in 1788, respecting the right of the Prince of Wales to the regency, see REGENT.

PRINCEPS SENA'TUS. Prince or first of the senate. In Ancient Rome, the citizen whose name was inscribed first on the list of the senate by the censors was so called. This high dignity was not connected with any office, and was conferred, in later times, only on those who were recognized as the most considerable citizens of the state. Before the second Punic war, it seems to have belonged to the oldest of those who had held the office of censor; but the first deviation from this practice was in favour of Fabius Maximus. This title was the first germ of the imperial authority of Augustus. (*See* SENATE.) There is a memoir on the subject in vol. xxiv. of the *Mémoires de l'Academie des Inscriptions.*

PRI'NCIPAL. (Lat. princeps, *chief.*) In Architecture, a main timber in an assemblage of carpentry. Thus, in a roof, the strong rafters used for trussing the beams are called principal rafters.

PRINCIPAL. The name by which the heads of the Scottish universities are distinguished.

PRINCIPAL. In the Fine Arts, the chief circumstance in a work of art, to which the rest are to be subordinate.

PRI'NCIPES. The name given to one of the four grand divisions of the Roman infantry. It was their duty to assume the initiative in an engagement, for which they were admirably qualified, being the choice men of the Roman army, and from this circumstance their name is said to be derived. The other three bodies were the velites, hastati, and triarii, which see. (See *Mém. de l'Acad. des Inscr.* vol. xxix.)

PRI'NCIPLE. (Lat. principium.) In Chemistry, a term sometimes applied to certain proximate components of organic bodies, such as *bitter principle*, *febrifuge principle*, *narcotic principle*, &c. This term, however, is now almost disused, it having been found that each bitter, febrifuge, narcotic, or other substance, generally contains a principle peculiar to itself upon which its powers depend, and that there is no such common or universal principle as was formerly supposed. For the same reason the term "principle of inflammability," or *phlogiston*, is rejected, as applied in common with "nervous principle," &c., to an imaginary existence.

PRI'NCIPLES. In the Fine Arts, those general and fundamental truths from which the rules and maxims of art are deduced. To each art particular principles are attached on which its theory is founded. These principles, before they can be said to have stability, must be found to depend on certain truths, which, recognized by every one, and indisputable, oblige the mind to concur in the deductions that result from them. Before a law in any art is laid down, it is necessary to trace it to the principles from which it springs, though there may be causes which prevent those principles being universally admitted: such as ignorance, prejudice, love of novelty, and the like. Indeed, there is an everlasting contest between truth and error in all human institutions. The former, like light, is acknowledged by all, though our passions and interests too often tempt us to obscure it; but, as darkness itself proves that light exists, so falsehood only enables truth to shine with greater lustre.

PR'INTING. (Fr. imprimerie.) Letterpress printing, to which this article is confined, is the art of taking impressions from engravings in relief.

The process is generally limited to printing from types, and from engravings on wood.

The history of its origin is enveloped in mystery; and this art, which commemorates all other inventions, which hands down to posterity every important event, which immortalizes the actions of the great, and which, above all, extends and diffuses the word of God to all mankind; this very art has left its own origin in obscurity, and has given employment to the studies and researches of the most learned men in Europe, to determine to whom the honour of the invention is due.

Some writers maintain that the art was practised as far back at least as the building of Babylon; and hold that the characters impressed on the bricks found on the supposed site of that city are literally printed: we are in possession of metal stamps, with words engraved in relief, which the Romans made use of to mark their various articles. On this subject Mr. Landseer, in his *Lectures on the Art of Engraving*, 8vo. 1807, observes, "Had the modern art of making paper been known to the ancients, we had probably never heard the names of Faust and Finiguerra; for, with the same kind of stamps which the Roman tradesmen used for their pottery and packages, books might also have been printed; and the same engraving which adorned the

shields and pateras of the more remote ages, with the addition of paper, might have spread the rays of Greek and Etrurian intelligence over the world of antiquity. Of the truth of this assertion I have the satisfaction to lay before you the most decided proofs, by exhibiting engraved Latin inscriptions, both in cameo and intaglio, from the collection of Mr. Douce, with impressions taken from them at Mr. Savage's letterpress but yesterday (in 1805). One of these is an intaglio stamp, engraved on stone, with which a Roman oculist was used to mark his medicines; the other, which is of metal, and in cameo, is simply the proper name of the (Roman) tradesman by whom it has probably been used, 'Titus Valagini Mauri.'" Of the latter stamp, the following impression is a facsimile:—

Papillon's relation of the two Cunio, who engraved on wood the heroic actions of Alexander the Great, and printed impressions from them in the year 1285, the truth of which has been defended by Zani, Ottley, and Singer; the print of St. Christopher carrying the infant Jesus across the sea, with an inscription and the date 1423 at the bottom on the same block, in the library of Earl Spencer; and the decree of the government of Venice, of the date 11th October, 1441, respecting "playing cards, and coloured figures printed," the art and mystery of making which had fallen to total decay at Venice, in consequence of the great quantity which were made out of Venice, and prohibiting the introduction of them under pain and forfeiture and fine,—a decree which carries the art of printing back into the 14th century: these circumstances, taken together, prove that the knowledge and the practice of the art of printing existed in Europe long before the time which is usually attributed to it, although it had not been applied to the multiplication of books.

According to Du Halde and the missionaries, the art of printing from engraved blocks of wood was practised in China nearly fifty years before the Christian era; and from the early commercial intercourse of the Venetians with that country, there is reason to believe that the knowledge of the art and of its application to the multiplying of books was derived from thence; for Venice is the first place in Europe of which we have any account in which it was practised, as appears by the decree above mentioned, which is the most ancient document in existence respecting printing; but the date of this application of the art, or the place where it was first practised, it is impossible to determine. From that decree and the existence of the print of St. Christopher, it would seem that it had been long applied to the production of playing cards, and of religious subjects; and when it was extended to books they were printed by the Chinese method, still in use, each page being engraved on a block of wood: and if this plan was followed, as most probably it was, from its being the most expeditious and the most correct,—of fastening a page of manuscript on the face of the block and engraving from that, instead of drawing the characters on the wood,—it would at once account for the diversity of characters found in the block books, which varied with the different handwritings of the scribes, and has completely puzzled the learned, who endeavour to ascertain the printer by comparing the characters with some other work; as well as for their great similarity to manuscripts, for which they were sold. This appearance too was aided by their being printed on one side of the paper only, the indention being removed by burnishing the back, and two leaves were pasted together, thus making them such perfect facsimiles of manuscripts as to require even at the present day great discrimination and even chemical skill to distinguish them from each other; and as these books had neither names, dates, nor places affixed to them, it is now impossible to ascertain by whom, when, or where they were executed; and thus the fabrication of these pseudo-manuscripts involved the first introduction of the art of printing books in Europe in complete obscurity.

About the year 1450, the great and accumulating expense of engraving blocks for each separate work of the increasing number of books produced by means of printing, led to the important improvement of the art of casting separate metal types, and substituting them for the wooden blocks previously used. This formed a new epoch in the art, and is now termed, erroneously, the origin of printing. After a lapse of many years, several cities claimed the honour of this invention, but time has reduced these claims to two,—Haarlem and Mentz; and this rivalry has employed the studies and the pens of many learned men, who have laboured to prove the respective claims of these cities to the imaginary honour of the invention of printing; for what can be more imaginary than such an honour? seeing the art had been practised in Europe, privately and publicly, in a modified form, for sixty or seventy years previously to the period which forms the subject in dispute. The claims of Haarlem rest upon the statement of Hadrian Junius, who gives it upon the testimony of one Cornelius, who had been a servant of Laurence Coster, for whom the invention is claimed; but this testimony, is our opinion, utterly worthless. Modern research gives the credit of the introduction of moveable metal types (unquestionably a grand *improvement*), to Peter Schoeffer, the assistant and son-in-law of John Fust or Faust of Mentz, so well known in Europe as Dr. Faustus. Of two writers who have supported the respective claims of these two places, it has been observed, that it now seems to be allowed that Heinecken has paid too little attention to the antiquity of the claims of Haarlem, and Meerman infinitely too much.

The first edition of the *Speculum Humanæ Salvationis* was printed by Coster at Haarlem, about the year 1440 as is supposed, and is one of the earliest productions of the press of which the printer is known, and of which we shall have occasion to speak hereafter. But the celebrated Bible, known as the "Mentz Bible without date," is the first important specimen of printing with metal types: this was executed by Gutemberg and Fust, between the years 1450 and 1455, and was the occasion of the secret being divulged, of producing books by mechanical means, as is mentioned in the article Black Letter. Then followed "the *Psalter*, of 1457," by Fust and Schoeffer. These works are executed in such a manner that, with all our boasted skill, and our improvements in the art, we are decidedly of opinion, perfect facsimiles, taking the ink and workmanship into account, could not have been executed in England so lately as twenty-five years ago. When the secret was made known, books avowedly printed issued from the press in all parts of Europe, far beyond what could have been calculated upon from a new discovery; for before the year 1500, there were printing offices in upwards of 220 places,—in Austria, Bavaria, Bohemia, Calabria, the Cremonese, Denmark, England, Flanders, France, Franconia, the Frioul, Geneva, Genoa, Germany, Holland, Hungary, Italy, Lombardy, Mecklenburg, Moravia, Naples, the Palatinate, Piedmont, Poland, Portugal, Rome, Sardinia, Upper and Lower Saxony, Sicily, Silesia, Spain, Swabia, Switzerland, Thessalonica, Turkey, Tuscany, the Tyrol, Venice, the Veronese, Westphalia, Wirtemberg, &c. The number of places in which the art was practised, the wide extent to which it had spread in so short a space of time, combined with the skill which the early printers displayed in their works, appear to us to be totally incompatible with the date generally assigned to the invention; and we are of opinion that, after having been long practised in private, it emerged into publicity in a state nearly approaching to perfection.

It is impossible in this short and rapid sketch of the history of the art to enter into detail, or to trace its progress in the different cities and towns, or even in the different countries where it was first publicly practised after the secret was divulged: in fact it would be impossible to arrive at any satisfactory conclusion; for as the first printers neither affixed their names, dates, nor places where their productions were executed, the greatest research could only result in vagueness and uncertainty. There has been great difference of opinion among bibliographers who have written on the subject, even respecting the first edition of the Latin translation of the Bible; and Meerman has enumerated ten ancient editions without date, in favour of the priority of each of which pretensions have been advanced and supported.

William Caxton is generally regarded as first who introduced the art of printing into England, and practised it at Westminster; but a prior claim is advanced in favour of Oxford, which has occasioned much controversy. Dr. Dibdin, in his *Typographical Antiquities*, says, "Although Caxton is called by me the first English printer, yet I fully believe in the authenticity of the Oxford edition of the *Exposicio sancti Jeronimi in simbolo apostolorum*, &c.. of the date of 1468, which was printed by a foreigner at Oxford, who was interrupted in the prosecution of his typographical labours." Several copies of this work are in existence: one is in the Bodleian library, another in the public library at Cambridge, and a third in the British Museum: Herbert mentions a fourth in the Earl of Pembroke's library; a fifth in All Souls library, of which a doubt may be entertained; and Hearne speaks of a sixth copy in the school tower at Oxford. Those who deny the priority for Oxford argue that the date is incorrect, either from accident or design; that being in Roman numerals an X is omitted, and that the real date of the book should be MCCCCLXXVIII.

Caxton, during a long residence on the Continent on

commercial affairs and political missions, in the reign of Henry VII., acquired a practical knowledge of the art, and on his return to England established a printing-office in a chapel adjoining to Westminster Abbey, where for many years he was indefatigable in translating and preparing works for the press, and in printing them; and to him may be fairly ascribed the merit of being the first to introduce the practice of printing generally into England. He printed many books on a variety of subjects; and all the productions of his press are objects of great interest to book collectors. He commenced printing in England about the year 1474, and was followed by Wynkyn de Worde, Richard Pynson, &c.

In the Privy Purse Expenses of Henry the Seventh are the following entries:—

"June 6, 1499. To the Printers at Westmr, £1."

"Nov. 1, 1504. To Richard Pynson the Prynter, in rewarde, £1."

"24. For pryntyng of new Colletts, £1 13s. 4d."

"July 12, 1505. To Ric. Pynson opon a prest for massebokes to be printed, £10."—*Excerpta Historica*, 8vo. 1833.

Dr. Dibdin relates, that, in 1524, Dr. Robert Wakefield, chaplain to Henry VIII., published his *Oratio de Laudibus et Utilitate trium Linguarum, Arabicæ, Chaldaicæ, et Hebraicæ*, &c. 4to. The printer was Wynkyn de Worde; and the author complains that he was obliged to omit his whole third part, because the printer had no Hebrew types. We have now in the British founderies, in addition to the Roman and Italic characters, Arabic, Armenian, Coptic, Domesday, Engrossing, Ethiopic, Etruscan, German, Greek, Alexandrian Greek, Gothic, Hebrew, Hibernian or Irish, Malabaric, Malayan, Nagari or Brahmin, Persian, Philosophical, Runic, Russian, Samaritan, Sanscrit, Saxon, Sclavonian or ancient Russian, Script in imitation of writing, Swedish, Syriac, Tamoul, Télegú, Turkish; also black letter, and music; and, in addition, a great variety of fancy types.

The first book in which Greek types occur is Cicero's *Offices*, printed in the year 1465, in which the characters are so imperfect that the words are with difficulty deciphered; and the first book printed in Roman characters was Cicero's *Epistolæ Familiares*, by Sweynheim and Pannartz, at Rome, in 1467. The Italic type was the invention of Aldus Manutius, the celebrated printer at Venice, about 1500, and dedicated by him to the States of Italy, from which it took its name.

The art appeared to start into publicity in a state of perfection. As it extended, the workmanship became much inferior; so that while the productions of the first printers were executed in a very superior style, and the embellishments showed a great proficiency both in design and engraving, the productions of their competitors had all the crudeness and imperfection of a new invention; and in the 17th century it had retrograded to a very low state. At the commencement of the 18th century, Caslon made great improvement in types; and about 1750 Baskerville of Birmingham also made great improvements, both in types and printing, which were subsequently carried on by Bensley, Bulmer, Corrall, Davison, M'Creery, Whittingham, and a few others, in London; the Foulis at Glasgow; the Ballantynes in Edinburgh; Bodoni at Parma, and Didot at Paris.

Many of the manuscripts of the 14th and 15th centuries were written in a beautiful manner, and embellished by borders round the pages, and by the large letters at the commencement of chapters being drawn and coloured with brilliant colours, heightened with burnished gold, and finished with taste, delicacy, and great ability, so as to produce a most splendid effect. These were called illuminated manuscripts. On the first production of books by the process of printing these ornamental letters were left blank, and both these letters and the borders were finished by hand in the usual manner, which gave to the book a perfect resemblance to a manuscript, of which it became by these means a complete facsimile. This is the case with the Mentz Bible by Fust and Gutenberg. The first printers soon began to print these large ornamented letters, the letter itself being in some instances red and the ornamental part blue, in others the letter is blue and the ornamental part red; and these were afterwards finished by hand, as is apparent in the Psalter of 1457, printed by Fust and Schoeffer, who also showed great ingenuity and skill in the large letter B in the same book, which is printed with red ink, and the ornamental part, consisting of a flourished line, as if it had been drawn with a pen, extending from the top to the bottom of the folio page, with blue ink. Of two copies which we have examined, one was in the library of Geo. III., at Buckingham Palace, and the other is in the possession of Earl Spencer.

The first edition of the *Speculum Humanæ Salvationis*, which was printed at Haarlem, about the year 1440, by Laurence Coster, has engravings on wood printed in a different coloured ink from the body of the work. A copy of this rare and curious work, which we examined some years ago in the valuable collection of Messrs. Longman, impressed us momentarily with the idea that the engravings were pen and ink drawings, and that the ink had turned brown with age, so precisely was this effect produced by the tone of the ink.

We mention these early specimens of printing with coloured inks, and in the case of the Psalter having two blocks of wood with two different colours, as being produced by means of the press, coeval with the generally received opinion of the invention of printing, to show the impossibility of the case. For, looking at the freedom of the engraving in the letter B, and the skill of the workman in printing it, it must be evident to every person conversant with the art that this perfection could only be obtained by long practice; and the contrast between these productions of the first practitioners and their competitors, when the art became public, puts the question beyond a doubt, as an examination of the facsimiles given by Heinecken from Fables printed at Bamberg about 1461, from the *Legendes* printed at the same place about 1470, and also the Fables of Æsop by Caxton, will, we think, satisfy the most scrupulous and sceptical.

Towards the end of the 15th century the art was extended to the imitation of pen and ink sketches with a coloured ground, by the great masters of painting; and in a few years it was further extended to the imitation of drawings in clare-obscure, and that with such success as to induce some of the first artists to encourage it by drawing the subjects on the blocks. The first practisers of this extension of the art were, Michael Wolgemuth of Nuremberg, who furnished the designs for the *Nuremberg Chronicle*, and also engraved them on wood, and Mair, a native of Landshut, the disciple of Martin Schön; between whom the priority rests of printing in clare-obscure. After them were Girolomo Mocetto, Lucas Cranach, Baldassar Peruzzi, Hans Burghmair, and Ugo da Carpi (who has been generally regarded as the inventor of this style of printing, but dates prove this opinion to be erroneous), Domenico Beccafumii, John Ulric, Albert Altdorfer, Hans Baldung, Lucas Jacobs Leyden (called Lucas Van); all these were born in the 15th century. In the 16th century, there were Antonio da Trenta, Giovanni Nicolo Vicentino (called Rossigliani), Herbert Goltz or Goltzius, Andrew Andreani, Henry Goltz or Goltzius, Abraham Bloemaert, Paul Moreelze, Bartolomeo Coriolano, Giovanni Batista Coriolano, Christopher Jegher, George L'Allemand, and Frederick Bloemaert. In the 17th century, there were Louis Businck, Vincent le Sueur, Antonio Maria Zanetti, Nicholas le Sueur, Comte de Caylus, Edward Kirkhall, and John Baptist Michael Papillon. This last-mentioned engraver, in his treatise on *Engraving on Wood*, expressly states that Albert Durer engraved some subjects in clare-obscure, and that he had examined them in the collection of the king of France; Parmigiano also superintended the printing in this manner of a number of his own designs; Titian, Raffaelle, and other eminent masters made designs on the blocks for printing; and the author of *An Enquiry into the Origin of Printing in Europe* states, that "one of the greatest princes and connoisseurs of our age used to say, he saw nothing in prints that could give him the pleasure he received from looking at the wood prints, done in chiaro-oscuro by Hugo di Carpi." This prince was the Duke of Orleans, regent of France.

After these were John Baptist Jackson, who executed a number of subjects, of a large size, in clare-obscure, copied from celebrated paintings in churches in Italy, and from private collections; he afterwards established a manufactory at Chelsea for printing paper-hangings in oil colours, a speculation, however, which was unsuccessful. Some of his productions printed in colours were complete failures, the oil having spread in the paper; and the subjects being in the first instance engraved with strong lines, they have the appearance of coarse engravings coloured by children. Jackson flourished from 1720 to 1754. Mr. John Skippe, an amateur, executed many subjects in clare-obscure very adroitly.

Gubitz, an engraver at Berlin, has produced a great number of subjects printed in colours, of a very superior character, but none of them can be called imitations of drawings. The writer of this article was the first who attempted to imitate drawings in water colours by means of the common printing press, and accomplished the applying of all the colours used by artists to the composition of printing ink, thus serving as a pioneer to more skilful persons who might devote themselves to this branch of art; and he succeeded in producing facsimiles of the drawings of different artists so as to deceive every one who examined them. Messrs. Whiting and Branston, of Beaufort House, applied printing in coloured inks to the prevention of forgery, and to embossing on paper; and Messrs. Vizetelly and Branston have produced some very tasteful things in colours; but neither of these establishments has, to our knowledge, turned their attention to the imitation of drawings. Mr. Baxter is now pursuing the subject, and has executed many very superior specimens in a manner that would have been deemed totally im-

practicable twenty-five years ago. The result is confirming the most sanguine expectations we ever entertained on the subject; and we are decidedly of opinion that the powers of the printing press in producing works of art are far from being fully developed.

The art of taking impressions in gold from types, and from engravings on wood and metals in relief, generally called printing in gold, is executed most successfully by the common printing press. It is also accomplished with bronze of different colours in the most delicate engravings; but however beautiful the effect of bronze may be at first, it unfortunately is not permanent.

After this brief sketch of the history and progress of the art of printing in Europe, an art more important in the effects it has produced on the human mind, and consequently on the state of society, than any other that has ever been practised, we shall lay before the reader a short outline of the practical part, for the better understanding of which, we shall subjoin a glossary of the chief technical terms in common use.

The first operation, called composing, is to arrange the separate letters called types (*see* Types) into words, lines, and pages. These pages, being placed upon a large flat surface, called an imposing stone, in such an order that when they are printed, and the sheet of paper is folded, the pages will follow each other consecutively, are then wedged up in an iron frame, termed a chase. This operation is styled imposing.

A printing press is a machine on which the matter to be printed is laid on an even surface horizontally placed, either of stone or iron; and the pressure upon the types is produced by a parallel surface of wood or iron, technically a platen, by means of a screw, or lever, or both combined. *See* Press.

Perhaps the most satisfactory way of explaining the process generally will be to take a printing-office just commencing, and describe the whole arrangement, and follow, in the order of its proceeding, the execution of a work from its being put in hand to its completion.

The office having been supplied with all the necessary materials; viz. frames, cases, case racks, bulks, boards, board racks, imposing stone, furniture, quoins, mallet, shooting-sticks, brass rule, chases, and types, in the quantity and variety that may be judged necessary; and also presses with their accompaniments, banks and horses, with a sink, lye trough, wetting trough, and paper boards; and in the warehouse, with a gathering table, poles, a peel, and a press to press the books before they are delivered, — it may be said that the office is in a state to commence business.

The compositor now proceeds to lay the letter into as many cases as may be judged expedient in the first instance (*see* Case), laying the Italic in cases distinct from the Roman, each letter or sort in the box appropriated to it: having done this with one fount, he will put the cases into the case rack, and proceed with another fount, till the whole of the letter is laid; he will put the superfluous sorts either into a fount case or into coffins; and he will then be ready to take copy.

The pressman has to adjust his press, place the footstep so as to give him the greatest advantage in the pull, fix the rounce, place the girths so that the carriage shall run in and out properly, fix the back stay, justify the platen so that it shall bear equally on all parts of the form, and cover his tympans and frisket; and he is also ready to proceed in his work.

The compositor having taken copy, and received directions respecting the measure, the length of the page, any peculiarity in the spelling of particular words, the use of capital letters, the punctuation, the words that are to be in Italic or small capitals, and any other directions that may be deemed necessary, proceeds to make his measure, and cut a composing rule; he then begins to compose, letter by letter, till he has formed a word; he separates this from the following word by a space, and so continues till he has composed a line; he then justifies this line, by increasing the space between the words or lessening it according to circumstances, so that the line shall be tolerably tight in the composing stick; and thus proceeds till he has completed a page: after having set the head line and direction line with the signature, he ties a page-cord round it, to preserve it from falling asunder, puts it on a page-paper, and places it on the bottom of his frame; and thus continues, page after page, till he has composed a sheet.

It may be necessary to state that every line is of the same length, whether the types fill it out or not; the last line of a paragraph, lines of poetry, and short lines of any other description, are filled up with quadrats to the proper length, in order that they be secured from derangement by being wedged up in the chase; which is termed locking-up.

The pages are then taken to the imposing stone, and arranged in the proper order; the page-papers removed; a chase is then placed over them (*see* Chase), furniture put about them (*see* Furniture), and the page cords taken away; proper quoins are then selected, and the form is locked up. It is then taken to a press, and one impression is printed; this is styled the first proof, which is folded and taken to the reader with the copy; a boy reads the copy to him, while he examines the proof and marks the errors of the compositor, and puts a query to any doubtful matter for the author's consideration; the proof is then returned to the compositor, who corrects the errors and mistakes, and a second impression is printed with more care, and generally on better paper; this is styled a clean proof; it is examined by the first proof to see that the errors of workmanship are corrected, which is termed revising, and then sent out with the copy to the author; he makes what alterations and corrections he may think necessary (*see* Correcting); these are corrected by the compositor; another impression is printed, revised, and read finally and with care for press; the margin is then adjusted (*see* Margin); and the corrections being carefully made, it is taken to the press to be printed off.

In the mean time, after the author has returned the sheet for press, the warehouseman delivers out the proper quantity of paper, which the pressman wets, by drawing the paper, to the extent of three, four, five, or six dips for each quire, through clean water, according as the paper may be hard-sized or porous, and also as the form may be solid or open; the paper as it is wetted is laid upon a board, opened out, and another board is laid upon it with weights; on the following day it is turned, which causes fresh surfaces to come into contact with each other, and diffuses the moisture equally throughout every part of the heap; it will be in good condition to print on the next day. This wetting the paper causes it to receive the impression of the ink in a much more perfect manner than it could possibly be made to do if dry.

The pressman having received the forms lays the inner form on the press, and prints one copy, which is called a revise; this he takes to the person appointed to revise it, and while that is doing proceeds to secure the form on the table of the press by means of quoins; to place his tympan sheet; to fix the points which make small holes in the paper that enable him to cause the pages to fall precisely on the back of each other when the second side of the paper is printed, and to produce an even and uniform impression in all the pages; he then cuts his frisket, which preserves the margin of the paper clean, and, when the revise is corrected, proceeds to ink the surface of the types by means of balls or rollers. When the whole impression of one side of the paper is printed, he lifts the form off the press, washes the ink off the face of the type with lye, and rinses it with water. He then proceeds in a similar manner with the outer form, which completes the sheet; and thus sheet after sheet.

If it be intended to have large paper copies of a work, the alteration of margin is made when the number of small paper copies is printed off from each form.

When the sheet is printed the compositor lays it up, distributes the letter, and proceeds, sheet after sheet, till the body of the work is finished; then the title, dedication, preface, introduction, contents, and any other prefatory matter is proceeded with, these being always printed the last.

The warehouseman then takes the printed sheets away, and hangs them up on poles to dry, varying the number of sheets hung up together from five or six to ten or eleven, according to the state of the weather, the heat of the room, or the pressure of business; when these sheets are dry they are taken down from the poles, carefully knocked up, and put away in the warehouse in piles: when the book is nearly finished from ten to fourteen consecutive sheets are laid upon the gathering table in order, and collected sheet by sheet by boys, who deposit each gathering in a heap at the end of the table, which is generally what is styled a horse-shoe table, so that when a boy has deposited his gathering he has only to turn himself and begin again. These gatherings are then carefully collated, to ascertain that the different sheets are correct and in order, and folded up the middle. When the work is finished the gatherings are put together, one of each, which forms a copy of the work, and pressed; the work is now completed, and awaits the order of the bookseller, &c. to deliver the copies either to himself, the bookbinder, or to others, according to circumstances.

A new method of obtaining impressions from types by means of cylinders has been introduced, and the power generally employed is steam. Mr. König, a Saxon, had considered that steam might be employed with advantage to expedite the process; but not receiving encouragement on the Continent to enable him to prosecute his plans, he came to England in 1804, and, after explaining his views to some of the principal printers in London, Mr. Thomas Bensley, Mr. George Woodfall, and Mr. Richard Taylor embarked in the undertaking, but Mr. Woodfall soon withdrew. After innumerable experiments, and a great outlay of capital, the result was not satisfactory; but the experience gained by prosecuting these experiments resulted in the production of a machine to print with cylinders instead of a flat surface, as was the case with the printing press, which was limited in the size of

the paper by the size of the press and the power of the pressman. In cylindrical printing, by which the pressure is communicated in lines, the size may be very considerably increased.

The first machine that was constructed was capable of printing 1000 copies per hour of double demy paper on both sides, while a press is estimated to print 250 copies of a single sheet on one side only in the same time.

When this machine was completed, the proprietors of the *Times* newspaper, ever ready to adopt any improvement that would expedite its publication, without regarding expense, agreed with the patentees for two machines; and on the 28th of November, 1814, the *Times* was published, executed by cylindrical printing, the moving power being steam: these were the only machines constructed under the first patent.

Various improvements and simplifications of this complex machine were soon effected by different ingenious men, and were adopted by many printers. They have become invaluable for the publication of periodicals where the number of copies is great, and also for newspapers; for their power of printing sheets of paper of a size far beyond the capability of any press, and their rapidity of throwing off copies, enable the editors to increase the size, and to delay commencing the printing off for a considerable time later than before their introduction, and thus avail themselves of any intelligence that might arrive in the interval.

Perhaps the most complete machine for printing one side of the paper is that used at the office of the *Times*; the carriage on which the pages to be printed are laid travels under the printing cylinders, of which there are four, and back again nineteen times in a minute, producing two impressions in going, and two in returning, or seventy-six in a minute, being 4,560 copies of four pages of that newspaper in the hour, at its ordinary rate of working. The paper is laid on at both ends of the machine, two persons laying on at each end; and the printed sheets are delivered two at each end.

The types are inked by means of rollers, and the apparatus for this purpose was the invention of Mr. Edward Cowper; the paper is secured in travelling round the cylinders by means of tapes, as first practised by Mr. König: the chief improvements in this machine are known as those of Messrs. Applegath and Cowper, by the former of whom it was constructed and fitted up.

This machine has the appearance of four single machines formed into one, and working at less speed than separate machines are in the habit of doing, many of which are capable of printing 1500 per hour; and we have no hesitation in saying, that if it were requisite for the sake of despatch, the principle might be extended, and a machine constructed to print 6000 or 8000 an hour without difficulty.

The idea of cylindrical printing in England originated some years anterior to Mr. König submitting his plan, for the late Mr. William Nicholson took out a patent for the purpose, dated 29th April, 1790, but it was never acted on; and, as to the use of steam as the motive power, the late Mr. Alexander Tilloch is known to have stated previously to the introduction of these machines, that he had long had it in contemplation to apply steam as the power to print off the *Star* newspaper.

The late Sir William Congreve took out a patent for a machine to print two colours at once, which was made by Messrs. Donkin and Company, and completely answered the purpose. This machine was intended to print stamps and bank bills, which Sir William stated would be inimitable, except by the machine of which he was the patentee; but he was too sanguine, and the opinion was fallacious, for nothing in the process of printing is more easy to execute at the common press by a common workman than this inimitable plan for preventing forgeries.

Glossary to the Article Printing.

Alteration of Margin, is increasing the space between the pages, so as to enlarge the margin of a book, and make it proportional in large paper copies.

Back Stay, is a girth or strap of strong leather attached to the back of the carriage, and fastened to the hind part of the press: its use is to check the carriage in running out beyond the point which will allow the tympan to rise clear of the front of the platen.

Balls are used for coating the face of the type or engraving with ink for the purpose of obtaining impressions. They consist of the ball-stock, stuffed with carded wool, and not many years ago were covered with an undressed sheep-skin, the hair taken off, termed a pelt. The noisome smell which these balls occasioned in a printing-office by the means used to keep them in good working order, induced many persons to turn their attention to the providing of a substitute for them; but long without success: at length Mr. B. Foster introduced composition balls, made of glue and treacle melted together and cast in a dished mould, so that the edges are thinner than the middle, and attached to a piece of canvass as a substitute for the pelt; these balls were found to answer so well, and be so free from any noxious smell, that they have generally superseded the pelt balls.

Bank. A table placed at the side of a press, on one end of which the horse containing the paper to be printed is laid, and at the other the sheets printed during the operation.

Board Rack. Grooves formed in some recess, or under the imposing stone or a bulk, or in a closet, to receive letter boards on which types are placed that are not in immediate use.

Carriage. That part of a press on which the types are placed to be printed, which is run in till they are immediately under the platen, and, when the impression is taken, run out, in order to change the sheet of paper, and to ink the types again.

Case Rack. A frame of wood of the width and depth of a case, with ledges attached to the inside of the upright parts to receive those cases which are not in use.

Coffin. A piece of strong paper twisted into a conical shape like a sugar paper, into which any superfluous types are temporarily deposited. Also that part of the carriage of a wooden press in which the stone is bedded.

Composing Rule. A piece of brass rule, the width of which is equal to the height of the types, cut to the length of the line, and laid in the composing stick, upon which the compositor arranges the types; it facilitates the process, and by means of it he empties his stick when it is full.

Composing Stick. An instrument of simple construction, in which the compositor arranges the words and lines. It has a slide, which is secured by a screw, by means of which he is enabled to make the lines of any length that may be required.

Direction Line. A line of quadrats at the bottom of each page, in which is inserted the first word of the next page, which is called the catch-word; in the first page of each sheet there is also inserted in it the number of the volume, if more than one, and the signature.

To Distribute. To replace the letters in their respective situations in the cases after a sheet has been printed off, to enable the compositor to proceed with the work.

Footstep. An inclined plane fixed under the front side of the press, for the pressman to place his foot upon when at work, to enable him to exert his strength to advantage.

Form. A chase with one or more pages wedged up in it.

Fount Case. A case of large dimension in which the superfluous sorts of a fount are placed, as a depôt, till they be wanted.

Frame. It is made of wood, of a height to suit a man standing to work at it, on which the cases are placed. It is much higher at the back than the front, which brings the most distant boxes nearer to the compositor's hand.

Frisket. A light iron frame, attached to the tympan by joints or pivots, which turns down upon the tympan over the sheet of paper to be printed, to preserve the margin clean, and to retain the paper in its position; to effect this, the frisket is covered with paper, and openings cut in it the size of the pages to be printed.

Girths. Two pieces of girthweb or strong leather, fastened at one of the ends to the wheel, and wound different ways round it, and the other ends attached to the extreme ends of the carriage; by this means turning the rounce one way causes the carriage to run in under the platen, and turning it the reverse way causes it to run out again.

Head Line. The line at the top of the page, which contains the folio or number of the page, and frequently the title of the book, or the subject of the chapter or of the page.

Horse. An apparatus of a desk-like shape, placed on the bank close to the tympan of the press, on which the paper to be printed is laid.

Inner Form. The chase and pages in proper order, wedged up, which contains the 2d, 3d, 6th, 7th, 10th, 11th, 14th, and 15th pages of a sheet in octavo; it invariably contains the second page of a sheet, whatever may be the size of the book.

Justifying. Putting equal space between the words in each line; making the lines of precisely the same length; placing the marginal notes opposite the references; making the pages uniformly of one length; and adjusting any peculiar matter, so that the whole shall be tight and proper when wedged up.

To Knock-up. At press, it is for the pressmen to make a pair of balls. In the warehouse, it is to make the printed sheets even at the edges, which is performed by taking hold of a parcel of sheets by the two edges, holding them slack in the hands, and letting them fall on their bottom edge by their own weight, then by a sleight of hand throwing them flat on the board, repeating the operation till all the sheets are even at the edges, when they are placed in piles until they are gathered.

To Lay-up. This is the operation of washing the ink off the types after the impression is printed, by laying

the form on a letter board, loosening the quoins, and working the letter with the hand, pouring on it plenty of water to clean the types for distribution.

Letter Board. A board on which pages of types are placed for distribution, and also when they are not immediately wanted. There are two ledges of wood grooved in on the under side, which project a little more than an inch, on which it rests, which allows it to be set over other types on boards without putting them in confusion.

Lye Trough. A shallow trough, lined with lead, sufficiently capacious to admit a board on which a form is laid; this trough has some lye in it, with which the surface of the letter, the chase, and the furniture is brushed over, to remove the ink which has accumulated during the process of printing; the form is then taken out, set upon its edge, and rinsed with water. The lye is composed of water and pearlash.

Mallet. (Fr. maillet.) A wooden hammer, with which the quoins are tightened, and also loosened; and which is also used for general purposes.

Measure. (Fr. mesure.) The space in the composing stick between the end and the slide, which is the length of a line, however large or small the page may be, is styled the measure.

Outer Form. The chase and pages in proper order, wedged up, which contains the 1st, 4th, 5th, 8th, 9th, 12th, 13th, and 16th pages of a sheet in octavo; it invariably contains the first and last pages of a sheet, whatever may be the size of the book.

Page Cord. Small twine, even and strong, which is used to tie round the pages of types, to secure them from accidents till they are imposed, when the cords are taken off.

Page Papers. Pieces of stout and smooth paper, on which the pages of types in the progress of a work are placed in a safe place till a sheet is ready to be imposed.

Paper Boards. Boards on which paper is laid when wetted; also those boards used in pressing books; they are of various dimensions, according to the size of the paper. They differ from letter boards in being smooth and even on both sides.

Peel. A thin piece of wood with a long handle affixed to it, in the shape of the letter T; it is used for hanging the sheets of a book upon the poles to dry, and for taking them down again.

Platen. A thick piece of wood, or more generally now made of iron, perfectly level on its under side, attached immediately under the moving power of a printing press, which produces the impression.

Point. There are always two points used in presswork, when a sheet of paper is printed on both sides; they are made of thin iron, with a notch at one end, and a projecting spur or point at the other end; they are attached to the tympan by screws, and lie flat upon it; the spurs being under the sheet of paper to be printed make small holes in it, so that when the reiteration or second side is printed the spurs are placed in these holes, which cause the pages to fall exactly on the back of each other.

Poles. Long pieces of fir wood, about an inch and a half thick, and three or four inches broad, placed across the warehouse and other rooms in a printing-office, at about eight or nine inches apart, and about fourteen inches from the ceiling; their ends rest in notches cut in stretchers fastened to the wall. Their use is to hang the damp printed paper upon to dry, which is done with facility by means of the peel.

Quadrats. (Fr. quadrat.) Pieces of metal of the same body as the type, but cast lower in height; used to fill up short lines, and to form a blank line or lines where necessary; being cast lower than the type, they do not produce any impression on the paper.

Quoin. A wedge about half an inch thick and of various widths, to wedge up the pages of type in a chase.

Roller. (Fr. rouleau.) The roller has nearly superseded the use of balls for inking the surface of the types. It is formed of a composition of glue and treacle cast on a wooden cylinder, turning on its axis in a light frame.

Rounce. The rounce is the handle by which the carriage of the press, on which the form to be printed is laid, is run in under the platen and out again; it is fixed on the spit, which is the axis, that passes through the drum, a cylinder of wood on which one end of the girths are fastened. The whole apparatus is generally termed the rounce.

Run-in. The act of placing the carriage with the form of types under the platen, to obtain an impression. This is effected by turning the rounce.

Run-out. The act of withdrawing the carriage with the form of types from under the platen, by turning the rounce the reverse way from the preceding, after the impression is taken.

Shooting Stick. An implement for tightening and loosening the quoins that wedge up the pages in a chase. It is in the shape of a wedge, about two inches broad and nine inches long, and is usually made of box wood. In use the small end is placed against the quoin, and the other struck by the mallet.

Signature. A letter of the alphabet placed at the bottom of the first page of a sheet, and so on to each sheet consecutively through the alphabet, with the exception of the letters J, V, and W; their use is to facilitate collating a book, as a guide to the bookbinder in folding the sheets, and as a ready means of referring to any part of a work before it is bound.

Sink. A corner of the pressroom, generally inclosed and lined with lead, with loose boards upon the lead; in this sink are placed the lye trough and a wetting trough; it is here where the forms are washed, rinsed, and laid up. There is always a pipe to carry off the waste water.

Sorts. It is generally used in the plural; it means any letter, point, mark, space, or quadrat, that is either deficient or redundant in quantity. A work runs upon sorts; that is, a greater number of some particular letters are required than the regular proportion, an index for instance.

Space. A piece of metal cast lower than a type, so as not to print, used to separate words; they are of different thicknesses, so as to enable the compositor to arrange the words at equal distances from each other in the same line.

Tympan. A wooden frame attached to the carriage of the press by joints, and covered with parchment, on which the sheet of paper to be printed is laid; there is another frame called the inner tympan, which fits into this, also covered with parchment; between these are placed pieces of woollen cloth, termed blankets, which form a soft medium between the types and the platen that tends to produce an equal impression.

Tympan Sheet. A sheet of paper, the same that a work is printed on, laid upon the tympan, and fastened to it at the corners with paste; it is the guide on which the sheets to be printed are laid, by which means the margin is kept regular and uniform.

Wetting Trough. Two troughs joined together and lined with lead; one deep, containing the water; the other shallow, of sufficient size to contain a paper board. The paper is wetted for printing by drawing it through the water, and opening it out on the board.

PRINTING INK. A composition with which the face of types and engravings in relief are coated previous to obtaining an impression from them: it is made of different colours; but books, and the generality of printing, are executed with black ink. Its composition, generally speaking, is linseed oil boiled to a varnish, with colouring matter added to it. The preparation of this article was long kept a profound secret by the few manufacturers of it in England, who completely monopolized the trade, till Mr. W. Savage published a treatise on the subject, in which he gave the process in detail for making printing ink of every quality and colour, which may be consulted with advantage by those who are interested in the subject.

PRIOR, PRIORESS. (Lat.) The heads of certain convents of monks or nuns, which are thence denominated *priories:* the prior is inferior in dignity to the abbot.

PRISCI'LLIANISTS. In Ecclesiastical History, heretics of the 4th century; so named from Priscillian, bishop of Atila in Spain, who was put to death in A. D. 382 by Maximus, tyrant of Gaul, for heresy, on the accusation of another bishop, Ithacius: one of the earliest instances of persecution to death for that offence. The opinions of Priscillian and his followers are said to have been Manichæan; but it is remarkable that Sulp. Severus, himself sufficiently zealous against their doctrines, admits that their persecutor Ithacius was a man of disreputable character, and that purity and austerity of manners were often sufficient with him to ground an accusation of Priscillianism. This affords a curious parallel with the history of the 12th and 13th centuries, when accusations of Manichelsm were liberally brought against sectaries whose avowed tenets extended only to the reformation of ecclesiastical matters and denial of the church's authority. (See *Mosheim*, cent. iv. part 2.)

PRISM. In Geometry, a solid contained by planes of which two that are opposite are equal, similar, and parallel, and all the rest parallelograms. Prisms take particular names from the figures of their ends, or opposite equal and parallel sides. When the ends are triangles, they are called triangular prisms; when the ends are square, square prisms; when the ends are pentagonal, pentagonal prisms; and so on. A *right* prism has its sides perpendicular to its ends; an *oblique* prism is that of which the sides are oblique to the ends. The solid content of a prism is found by multiplying the area of the base into the perpendicular altitude; hence all prisms are to one another in the ratio compounded of their bases and altitudes.

PRISM. In Dioptrics, a piece of glass or other diaphanous substance, in form of a triangular prism, employed to separate a ray of light into its constituent parts or colours by refraction. The prism is the instrument by means of which most of the remarkable phenomena of

light and colours are exhibited. *See* CHROMATICS, OPTICS, REFRACTION.

PRISMATIC COLOURS. The colours produced by decomposing light by a prism. *See* PRIMARY COLOURS.

PRISMATIC COMPASS. A surveying instrument, much used on account of its convenient size and form in military sketching, and for filling up the details of a map where great accuracy is not required. The construction is as follows: — The compass-card, divided into degrees and minutes, is attached to the needle and turns with it. On one side of the compass-box stands a perpendicular slip, called the sight-vane, having a long narrow perpendicular slit in it, along the middle of which a fine thread is stretched. On one side of the box, opposite to the sight-vane, there is a prism, through which and through the sight-vane an object is observed, and bisected by the thread. The use of the prism is this — the rays of light passing from the thread to the eye are refracted in passing through the prism, so that the thread appears to be prolonged and to intersect the circle on the card on which the divisions are; consequently, the magnetic azimuth of any object which the thread bisects is indicated immediately by the division with which the thread coincides. The angle between two stations is thus obtained, being equal when the stations are on opposite sides of the meridian to the sum of their azimuths, and to the difference of the azimuths when they are on the same side of the meridian. The card is divided to 15′ of a degree, which is, perhaps, a smaller angle than can be measured by this instrument. (See *Simms's Treatise on Mathematical Instruments.*)

PRISMOID. An imperfect prism; a figure resembling a prism, but not answering exactly to the definition.

PRI′SON. (Fr. prendre, *to take.*) Imprisonment is used in most civilized states for three purposes: for safe custody of persons charged with offences, for the detention of debtors, and for punishment; under which latter head the reformation of prisoners must be comprehended, as being properly only an adjunct to punishment. The first principles of order seem to require that these three classes of prisoners should be kept entirely distinct, and, if possible, in separate places of confinement; but even the former rule has been generally very imperfectly observed, while the latter is in most places impracticable by reason of expense. The alleviation of the horrors of imprisonment, by physical improvement of the condition of prisoners and the imparting of religious instruction, has been from very early times an object with philanthropists; but the adaptation of imprisonment to serve the end of punishment has been, comparatively speaking, only very recently attempted. The Society of the Brothers of Mercy, in Italy, paid much attention to the former subject in the 15th and 16th centuries; and the names of S. Carlo Bórromeo and St. Vincent de Paule have derived from it much of their lustre. But the earliest instance of a prison managed on any principles of policy and humanity seems to be that of the Penitentiary at Amsterdam, erected in 1595; an example which was soon followed by some of the German towns, especially Hamburg and Bremen. In England it is well known that the impulse of prison improvement was first communicated by the celebrated Howard, whose sufferings, when taken by a privateer and imprisoned at Brest, during the seven years' war, are said to have first directed his attention to the subject. The fruits of his observations, in his repeated visits to most of the prisons of Europe, were given to the world partly in his publications, and partly on examination before a committee of the House of Commons in 1774. To his suggestions, and those of Jonas Hanway, are principally owing the provisions of the 19 G. 3. c. 74. (passed in 1778), truly called the basis of succeeding legislation on the subject. Solitary imprisonment was then first instituted. The works of Neeld and others, and the labours of the Prison Discipline Society, (founded, we believe, chiefly by Mr. Fowell Buxton,) kept the attention of the public fixed on the subject. In 1813, the construction of the Milbank Penitentiary was begun, intended as a species of model prison; but that establishment, from many errors committed in its foundation and first management, was long before it answered in any degree the views of its projectors. Meanwhile practical improvement had proceeded much further in the United States of America, where the experiments of solitary confinement and of association in silence were both first instituted on any extensive scale, and have formed the basis of two different systems, which now divide the suffrages of observers. Europe has in this matter taken lessons from America; and the reports of French visiters (Messrs. Beaumont and De Tocqueville, 1834; Messrs. De Metz and Blouet, sent by government, 1837), of Dr. Juliers, sent from Prussia, and Mr. Crawford from England, have contributed largely to the present state of public opinion on the subject. In 1834, inspectors were appointed to report annually on the state of English and Scottish prisons, — a measure which had been earlier adopted with reference to Ireland; and their reports may be consulted with great advantage, both with a view to the actual state of prisons, and their prospective reform. The "Third Report of the English Inspector for the Home District" (1838) is particularly valuable, from the historical sketch it contains, and from the comparison there instituted between the separate and the silent systems. The chief heads of improvement in prison discipline which have been recommended or introduced since public attention was called to the subject are, 1. Inspection and control; 2. Classification; 3. Separate or solitary punishment; 4. The "silent" or non-intercourse system; 5. The introduction of labour; 6. Religious and intellectual instruction.—1. The first of these is matter rather of practical than theoretical development. The history of the plan originally suggested by General Bentham and his brother, the philosopher, which has formed, to a certain extent, the basis of later experiments, is mentioned under the head PENITENTIARY. 2. Classification, under the English gaol acts of 1823 and 1824, has been extensively introduced into prisons. It is of course a great improvement on the indiscriminate mixture of prisoners of all classes and characters which formerly prevailed; but as a means of reformation, or of punishment, it has not answered the views once entertained of it. And the reason is obvious: the only object of classification is the exclusion of the moral influence of more or less corrupted minds; but by no system of classification (and as many as fifteen classes have been introduced in some prisons) can this be excluded. In every class, whether arranged according to age, or degree of offence, or in any other practicable mode, there will probably be some unusually depraved characters; and then the experiment must fail. The only perfect classification is that which constitutes the basis of, 3. The *separate* system; namely, the entire separation of prisoners from each other in solitary cells. When this has been carried to excess as a means of punishment, namely, seclusion by day and by night, without labour, without employment, with only the occasional silent visits of the turnkey or the medical attendant, it has generally proved more than human nature can bear, at least for any time; but separate confinement *with* labour as an alleviation, and with occasional visits for religious consolation and instruction, is a very different mode of treatment. The separate system is that established in the great eastern penitentiary of Philadelphia, now in operation for ten or eleven years; and in that of Glasgow, — which may be mentioned as models in their kind. 4. The difficulty of enforcing solitary confinement, in some American prisons, seems to have led to the adoption of the *silent* system: of which the prison at Auburn, in Pennsylvania, affords the most celebrated instance. The prisoners work together in the day, but are prevented from all communication: at night they are separate. It was, we believe, introduced several years ago in the Maison de Force at Ghent. In England, it is in operation at Coldbath Fields, Wakefield, and elsewhere. With respect to the comparative advantages of the two systems, the work of Messrs. Beaumont and De Tocqueville may be consulted for an impartial summary of evidence, without the expression of decided opinion. (Part I. chap. ii. s. 3.) The "separate" was recommended in 1832 by the committee on secondary punishments; and is advocated by Mr. Crauford, in his *Report on the Penitentiaries of the U. S.* 1837, and in the 4th Report above alluded to; by Dr. Juliers; by Messrs. De Metz and Blouet; and by M. Moreau-Christophe in various works. The silent system seems to be supported by M. Lucas, *De la Reforme des Prisons*, 1836; while, in his *Théorie de l'Emprisonnement*, he attempts to reconcile the two; by Messrs. Berenger and Gasparin; and by Mr. Inspector Williams (4th Report, England; Northern and Eastern Division). The chief objections to the separate system are, — 1. As a punishment, its inequality, being felt far more severely by some than others; but to this it may be answered, that those who do feel it are precisely those whom it is most desirable to affect — the more depraved. 2. Its effects on the mind and passions in some respects; a very difficult and delicate subject, and by far the most serious charge against it. 3. That even as a system of reform, for which, in subjects presenting any prospect of amendment, it is best calculated, it is utterly useless in short terms of imprisonment. "Those best acquainted with the subject in the U. S.," says Mr. Williams, "conceive that two years' imprisonment are required before any impression can be made, and from four to six years to achieve the work of reformation." To the silent system, its enemies object,—1. The extreme difficulty of carrying it into successful operation. 2. Its supposed effect in irritating, degrading, and even brutalizing the minds of prisoners, by its vexatious discipline. They appeal in support of this position to the quantity of punishment (corporal, or by solitary confinement) which is required to carry it into effect. In Wakefield and Coldbath Fields, upon this system, 26,257 punishments were inflicted on 13,188 prisoners, or two on each on the average; while in all England the proportion was found to be 54,825 punishments to 109,495 prisoners, or one to two only. But this is explained in some degree, in the

latter prison at least, by the number of short imprisonments. 5. With respect to the introduction of *labour* into prisons of punishment, the chief question seems to be, whether it ought to form part of the punishment, and be of a vexatious and severe nature; or whether it should be used as an alleviation to the rigour of separate confinement, as a preparation of the criminal for re-entrance into society. The former is the principle commonly adopted in England; the ordinary sentence, for many offences, being imprisonment with *hard* labour, and with occasional intervals of solitary confinement; the treadwheel being the most common species of labour. On this subject the reader may consult the *original* article "Prisons" in the *Enc. Britannica;* but the views of the author are somewhat too dogmatically expressed. The policy and practicability of making prison labour pay or contribute largely towards the maintenance of the prison has not been much discussed in England; where, from our less economical habits, the experiment has hardly been tried. In America several are said to afford a revenue to the state. (See Messrs. De Beaumont and Tocqueville.) In Belgium they have long been rendered very productive; the works of the present very able inspector-general, M. Ducpétiaux, contain ample information on the subject. The 16th and 17th Reports of the Irish Inspectors refer largely to it: from the latter it appears that the cost of work has been more than repaid by the return in every prison; but it does not appear clearly what is comprehended under the former head, and the numbers seem not altogether accurate. There are, however, serious moral objections to plans combining economical advantage with punishment and reformation. It is impossible to conclude an article on this subject without noticing that terrible defect in our institutions, the want of any control over or provision for offenders discharged from prisons; a defect which the abolition of transportation, without any substitute, will render even more conspicuously injurious than it has hitherto been. Most of the best modern authorities on this subject are referred to in the course of this article: see also the article "Gefängniss" in the *Conversations Lexicon*, and the German works mentioned at the end of it; and the *Ed. Rev.* vols. xxii. xxx. xxxv. xxxvi.

The last prisons act is the 2 & 3 Vict. c. 56. (1839). By this act, *separate* confinement is for the first time distinguished from the severer punishment of *solitary* confinement. The justices are empowered to make rules for classification, &c., subject to the approval of the secretary of state. According to the reports of 1838, 133,312 persons were confined in the prisons of England and Wales during that year; of whom 23,808 were committed for trial at assizes and sessions, 56,736 on summary conviction.

PRISONS, MAMERTINE. Certain fearful places of confinement in ancient Rome, chiefly intended for state prisoners. They were constructed by Ancus Martius of large uncemented stones; and, from the specimens of them which remain, it is difficult to imagine a more horrible place for the confinement of a human being. There were two apartments, one above the other, to which there was no entrance except by a small aperture in the upper roof; and a similar hole in the upper floor led to the cell below, there being no staircase to either. The upper prison was 27 feet long by 20 wide, and the lower, which was elliptical, was 20 by 10; the height of the former was 14 feet, of the latter 7. None but persons of distinction had the privilege of occupying these prisons.

PRIVATEE'R. A vessel belonging to one or more private individuals, sailing with a licence from government, in time of war, to seize and plunder the ships of the enemy. The practice of granting commissions to privateers first became general in the war between Spain and the revolted Netherlands, at the end of the sixteenth century; when it was extensively made use of by the Prince of Orange as a means of annoying the Spanish trade.

PRI'VILEGE. (Lat. privilegium: defined by Cicero, lex privato homini irrogata.) In the ordinary acceptation of the word, a law, or an exception from the common provisions of law, in favour of an individual or a body. Privilege is said to be personal or real; that is, attached to the person only, or to the person in respect of a particular place; as to a member of one of the universities, an officer of one of the courts at Westminster. The privileges chiefly recognized by the English law are privilege of parliament (*see* PARLIAMENT), and the privilege to sue and be sued, according to particular provisions, allowed to officers and attendants in the courts of justice.

PRI'VITY, in Law, is a peculiar mutual relation which subsists between individuals connected in various ways; so that, besides those who are actually parties to a transaction, others connected with these parties are said to be privy to the transaction, and are bound by its consequences. Several sorts of privity are enumerated by writers on law; but those of most ordinary occurrence are three; privity of blood, of estate, and of contract. The former subsists between an ancestor and his heir; the second between lessor and lessee, tenant for life and reversioner created by the same instrument; and privity of contract between those who are parties to a contract, which species of privity is personal only.

PRIVY CHAMBER, GENTLEMEN OF THE. Officers of the king's household, instituted by Henry VII. Their proper duties are to attend the king and queen at court, in their diversions, progresses, &c. There are also four gentlemen ushers of the privy chamber, whose office is to wait in the presence chamber, attend on the king's person, and note affairs under the lord chamberlain and vice-chamberlain.

PRIVY COUNCIL. *See* COUNCIL, PRIVY.

PRIVY SEAL, LORD. The fifth great officer of state in England, who has the custody of the privy seal of the king, used to all grants, charters, pardons, &c. before they come to the great seal.

PRIZE. Any thing captured by a belligerent using the right of war: in common language, only ships thus captured, with the property taken in them, are so called. Prizes taken in war are condemned by the proper judicature in the courts of the captors: such condemnation is held to divest the title of the proprietor and confer a new ownership. In order to give jurisdiction to a court of prize, it is deemed necessary, by the law of nations, that the property captured should be in possession of the captors in their own ports, those of an ally, or of a neutral; but no belligerent power has a right to capture in the ports of a neutral country, or within a marine league of her shores; nor does a capture made then render the adjudication valid. Subject to capture are hostile property, *i.e.* the property of persons domiciled in a hostile country, and neutral property contraband of war. *See* CONTRABAND.

PRO'A, FLYING. A narrow canoe about 30 feet long by 3 feet wide, used in the Ladrone Islands. The lee side is flat, being the mere longitudinal section of the common form, and the head and stem exactly alike. A slight frame-work projects several feet to windward, bearing a small block of wood like a canoe: this float supports the vessel from oversetting to that side, as she would otherwise do, and the frame-work affords support for a weight acting against the pressure of the sail. The vessel is steered by a paddle at either end, and moves with great velocity, either backwards or forwards, being adapted to a side wind in running between two places. The sail is mat, with a boom, upon one mast. *Proa* is also the name for large boats used by the Malays, propelled both by oars and sails.

PROAU'LION. (Gr. πρό, and αὐλή, *a hall.*) In Architecture, the same as vestibule; which see.

PRO'BABILISM. In Theology and Ethics, a theory professed by some casuistical divines, chiefly of the Jesuit order, according to which it is lawful to follow a *probable* opinion in doubtful points, although other opinions may seem to the mind of the inquirer more probable. Those who teach this doctrine are styled *Probabilists.* This and the other tenets of the once celebrated science of casuistry are ably touched on by Mr. Hallam, in vol. iii. of his *Literature of Europe.*

PROBABI'LITY, THEORY OF. A very extensive and important application of analysis, having for its object the determination of the number of ways in which a future or uncertain event may happen or fail, in order that we may be enabled to judge whether the *chances* of its happening or failing are the greater, and in what proportion.

In this theory the word *chance* is used to signify the occurrence of an event in a particular way, when there exist two or more ways by which it may take place, and no reason can be assigned for its happening in one way rather than another. For example, if a die be thrown up into the air, it will necessarily fall on one or other of its six faces; but as we know of no reason why it should fall on the face marked one, rather than on that which is marked two, or on any other face, and as the circumstances are precisely the same in all the cases, we say the chance of its falling on any one face is equal to the chance of its falling on any other. Suppose, again, a die, having four of its faces white, and the other two black, to be tossed up. There are four ways in which the die may fall so as to turn up a white face, and two in which it may turn up a black face; we therefore say the chances of its turning up a white face are to the chances of its turning up a black face as four to two. In ordinary language, when an event is said to happen by chance, it is merely implied that the cause is unknown, or cannot be certainly appreciated.

The term *probable*, in its common acceptation, is applied to any contingent or future event, to denote that in our judgment the event is more likely to happen than not to happen. In mathematical language *probability* has a definite signification. Suppose 5 balls to be placed in an urn, 3 of them white, and 2 black; and, one of them being drawn out at random, let it be proposed to assign a measure of the probability of its being a white or a black ball. In th

case there are 5 chances in all, 3 of which are in favour of a white ball, and 2 in favour of a black. The probability of drawing at the first trial any particular ball will evidently be represented by the fraction $\frac{1}{5}$; hence the probability of drawing a white ball is $\frac{3}{5}$, and the probability of drawing a black ball $\frac{2}{5}$. Now it is obvious that the absolute number of balls in the urn will not affect the relative probabilities, so long as the proportion of white to black balls remains unaltered. Suppose, for example, the number of balls increased to 50, of which 30 are white and 20 black; the probability of drawing a white ball at the first trial must still remain the same, there being always 3 chances in favour of a white ball for every 2 in favour of a black. Whatever, therefore, the number of balls in the urn may be, the probability of drawing one of a particular colour must remain the same, so long as the ratio of the number of balls of that colour to the whole number in the urn remains unaltered. Hence, we derive the following definition, which is, in fact, the basis of the whole doctrine of probabilities: —

The probability of the occurrence of any event is measured by a fraction, the numerator of which expresses the number of chances favourable to the occurrence of the event, and the denominator the whole number of chances favourable and unfavourable.

This fraction is called the mathematical probability. It is important to remark, that all the chances are considered as equal; for example, that, in drawing a ball from the urn, any one ball has the same chance of being drawn as any other.

Every contingent event gives rise to two opposite probabilities,—one, that the event will happen; the other, that it will not; and the sum of these probabilities is always equal to unity. Thus, in the preceding example, the probability that a white ball will be drawn from the urn is $\frac{3}{5}$, and the probability that a black ball will be drawn (*i. e.* that a white ball will *not* be drawn) is $\frac{2}{5}$; and $\frac{3}{5} + \frac{2}{5} = \frac{5}{5} = 1$. In general, let m denote the number of chances favourable to an event, and n the number of unfavourable chances; then, the whole number of chances, or ways in which the event can happen or fail, being $m + n$, the probability that the event will happen is $\frac{m}{m+n}$, the probability that it will not happen $\frac{n}{m+n}$, and the sum of these probabilities is 1. Hence, if p denote the probability of the occurrence of any event, the probability that it will not occur is $1 - p$. For instance, let p = the probability that an individual of a given age will live over one year; then $1 - p$ is the probability that he will *not* live over the year, or that he will be dead within the year. As the individual must either be alive or dead, the sum of the probabilities must necessarily amount to *certainty*, which is represented by *unity*, and hence the probability of any contingent event is always a fraction less than unity.

Probability of simultaneous Events.—The probability of the simultaneous occurrence of several independent events is calculated as follows: — Let it be required, for example, to determine the probability of throwing aces with two dice. Let the dice be called respectively A and B. The probability that A will turn up ace is $\frac{1}{6}$; and if a person were to purchase the chance of receiving a sum of 36*l.* on the occurrence of this event alone, the proper sum he ought to pay for the chance is 6*l.* But, if the sum is to be received only on condition of A and B both turning up ace, the above probability will only be beneficial to him provided B also turns up ace. Now, the probability of this event is likewise $\frac{1}{6}$; therefore, the probability of receiving the sum is $\frac{1}{6}$ of $\frac{1}{6}$, that is $\frac{1}{36}$, and the price to be paid for the chance is $\frac{1}{6}$ of 6*l.*, that is, 1*l.*

The same reasoning may be applied to any number of independent events; and the conclusion, which is perfectly general, may be expressed by the following rule: — "The probability of the occurrence of several independent events is obtained by multiplying together their separate probabilities." Thus, let p denote the probability of an event A, q that of an event B, r that of an event C, &c.; then the probability of the joint occurrence of those events is expressed by the continued product $p\,q\,r$, &c.

Probability of successive Events.— The probability of the successive recurrence of the same or different events is determined precisely in the same manner. For example, let the probability be required of throwing ace twice successively with the same die. The probability of ace turning up at the first throw is $\frac{1}{6}$, and at the second $\frac{1}{6}$; the probability of ace turning up at both throws is therefore $\frac{1}{6}$ of $\frac{1}{6} = \frac{1}{36}$. Hence the probability that ace will not turn up *both* at the first and second throw is $1 - \frac{1}{36} = \frac{35}{36}$. This last probability, it is necessary to remark, is quite distinct from the probability that ace will not turn up in either throw, and which is found thus — The probability that ace will *not* be thrown at the first throw is $\frac{5}{6}$; and the probability that it will not be thrown at the second also $\frac{5}{6}$: hence, by the former rule, the probability that it will not be thrown at either throw is $\frac{5}{6} \times \frac{5}{6} = \frac{25}{36}$. This added to $\frac{1}{36}$, the probability that ace will be thrown both times, does not give the sum equal to unity, for there are still two cases to be taken account of. Ace may be thrown at the first throw, and not at the second; or ace may not be thrown at the first throw, but thrown at the second. The probability that ace will turn up at the first throw is $\frac{1}{6}$, and that it will not turn up at the second throw $\frac{5}{6}$; hence the probability that it will turn up at the first, and not at the second, is $\frac{1}{6} \times \frac{5}{6} = \frac{5}{36}$. The probability that it will not turn at the first, but turn up at the second, is $\frac{5}{6} \times \frac{1}{6} = \frac{5}{36}$; and the sum of these, added to the sum of the probabilities of the two former cases, gives a result equal to unity. A distinct enumeration of the different suppositions that may be made relative to the ace point, in two successive throws of the same die, will render this reasoning more obvious. The event can happen only in one of four ways, which, with their respective probabilities, are as follows: —

1. Ace at both throws, probability $= \frac{1}{36}$
2. Ace at neither throw, probability $= \frac{25}{36}$
3. Ace at first, not at second, probability $= \frac{5}{36}$
4. Ace at second, not at first, probability $= \frac{5}{36}$

And the sum of these fractions is $\frac{36}{36} = 1$.

This reasoning may be rendered general. Suppose m = the number of white balls in an urn, and n = the number of black balls in the same urn, and that when a ball has been drawn it is immediately replaced in the urn, so that at each trial the whole number of chances is $m + n$. Let p = the probability of drawing a white ball on any trial, and q = the probability of drawing a black ball; we have then $p = \frac{m}{m+n}$, and $q = \frac{n}{m+n}$. And first let us consider the probabilities of the different possible events that may happen on two trials.

The only possible ways in which the balls can be drawn in two successive trials are these four: —

1. First white, second white; probability $= p \times p = p^2$;
2. First white, second black; probability $= p \times q = p\,q$;
3. First black, second white; probability $= q \times p = p\,q$;
4. First black, second black; probability $= q \times q = q^2$.

Adding together these probabilities, we get

$$p^2 + 2\,p\,q + q^2 = (p + q)^2,$$

and the sum is equal to unity, as will be evident by substituting for p and q their values in terms of m and n.

It thus appears that the probabilities of all the different combinations that can be formed in two trials are respectively given by the development of the binomial $(p + q)^2$. It will be observed that the term $2\,p\,q$ gives the probability of drawing a ball of each colour in the two trials without distinction of order; that is, the white ball may be drawn either at the first or second trial.

Now, let the number of trials, instead of being two, be increased to any number u; the probabilities of the different combinations will be given by the development of the binomial $(p + q)^u$. This development is

$$p^u + \frac{u}{1} p^{u-1} q + \frac{u\,(u-1)}{1 \cdot 2} p^{u-2} q^2 \ldots.$$
$$+ \frac{u\,(u-1\,(u-2)\ \ldots\ (u-v+1)}{1\ .\ 2\ .\ 3\ \ \ldots.\ \ v} p^{u-v} q^v + \&c.$$

The first term p^u indicates the probability of drawing a white ball in each of the u trials, or that all the balls drawn will be white. The second term $u\,p^{u-1}\,q$ denotes the probability of drawing $u - 1$ white balls and one black ball in u trials, without regard to the order; that is to say, the black ball may be drawn at the first, second, third, or any other trial. The general term

$$\frac{u\,(u-1)\,(u-2)\ \ldots.\ (u-v+1)}{1\ .\ 2\ .\ 3\ \ \ldots..\ \ v} p^{u-v} q^v$$

gives the probability that in u trials $u - v$ white balls will be drawn, and v black balls, without distinction of order. If the probability of drawing the ball in a determinate order of succession were required; for instance, if it were required to determine the probability of drawing $u - v$ white balls successively, and then v black balls; the coefficient of the term must be suppressed, and the probability becomes $p^{u-v}\,q^v$.

The practical question that most frequently arises is, not to determine the probability of the repetitions of an event in any precise order, but the probability that the number of repetitions will exceed or not exceed a certain limit. Thus, in the preceding example, suppose it were required to assign the probability that not fewer than $u - v$ white balls will be drawn in u trials; it is evident that as the first term gives the probability of drawing u white balls, the second term that of drawing

$u - 1$ white balls, and so on, and as each of these combinations satisfies the condition, the required probability will be found by taking the sum of all the terms of the development of $(p + q)^u$ from the first to that in which the factor $p^{u-v} q^v$ appears, both inclusive. As an example, let it be required to determine the probability of throwing ace at least *twice* in four throws of the same die. Here we have $p = \frac{1}{6}$, $q = \frac{5}{6}$, $u = 4$, and $u - v = 2$, whence $v = 2$. Now the development of $(p + q)^4$ to the term in which $p^2 q^2$ occurs is $p^4 + 4 p^3 q + 6 p^2 q^2$, which, on substituting for p and q their values, becomes $(\frac{1}{6})^4 + 4 (\frac{1}{6})^3 \times \frac{5}{6} + 6 (\frac{1}{6})^2 \times (\frac{5}{6})^2 = \frac{171}{1296} =$ between $\frac{1}{7}$ and $\frac{1}{8}$. Again, suppose the question were to assign the probability of throwing ace at least *once* in four trials, we should have $u - v = 1$, and therefore $v = 3$. Now the term of the development of $(p + q)^4$ in which $p q^3$ occurs is the fourth, or last but one; the sum of the first four terms, therefore, gives the required probability. But the calculation of this sum is easy; for, since the sum of all the terms is $(p + q)^4 = 1$, and the last term is q^4, the sum of the first four is $1 - q^4 = 1 - (\frac{5}{6})^4 = 1 - \frac{525}{1296} = \frac{671}{1296}$.

Probability derived from Experience. — In what precedes it has been supposed that the number of ways in which an event can arrive are known *à priori*; but it may happen, and indeed does happen, in the greater number of the most important questions to which the calculus of probabilities is applied, that the number of chances favourable and unfavourable to the occurrence of any particular event is unknown, and that the ratio of the one to the other can only be inferred from considering the ways in which the event has been observed already to happen. Recurring to the case of the urn, — let us suppose the urn to contain a certain number of balls of different colours; but that the number of each colour is unknown, and that, from having observed the result of several trials, we have to determine the probability of drawing a ball of a particular colour at the next trial. The method of proceeding is as follows: — Taking a simple case; suppose the urn to contain only four balls, of two colours, white and black, and that on four successive trials (the ball drawn being in each case replaced in the urn) three white balls and one black have been drawn. Three hypotheses may be formed respecting the number of balls of each colour in the urn; and if $p =$ the probability of drawing a white ball, and $q =$ that of drawing a black ball, on any hypothesis, the three hypotheses, with the corresponding values of p and q, will be as under, viz.: —

1. 3 white, 1 black, $p = \frac{3}{4}$, $q = \frac{1}{4}$;
2. 2 white, 2 black, $p = \frac{2}{4}$, $q = \frac{2}{4}$;
3. 1 white, 3 black, $p = \frac{1}{4}$, $q = \frac{3}{4}$.

Now, on calculating from each of these hypotheses the probability of the event observed, namely, of drawing three white balls and one black in four trials, which probability, by what was shown above, is expressed by $4 p^3 q$, we have,

by 1st hypothesis, $4 p^3 q = \frac{27}{64}$,
by 2d hypothesis, $4 p^3 q = \frac{16}{64}$,
by 3d hypothesis, $4 p^3 q = \frac{3}{64}$.

The numerators of these fractions, which represent the relative probabilities of the event which has happened on each of the hypotheses, may be considered as giving the relative probabilities of the hypotheses as to the causes of the event, or to the state of the urn by which the event was determined; and, as one or other of these hypotheses must necessarily be true, the sum of their probabilities must be unity; whence the probability of each hypothesis is respectively

$$\frac{27}{46}, \frac{16}{46}, \frac{3}{46}.$$

This result may be expressed generally as follows: — The probabilities of the different hypotheses are found by dividing the probability of the event which has been observed calculated according to each hypothesis by the sum of its probabilities calculated on all the hypotheses.

Now, in order to find the probability of drawing a white ball at the next trial, we may reason in this manner: — If the first hypothesis be true, the chance of drawing a white ball is $\frac{3}{4}$, and the probability of the hypothesis being true is $\frac{27}{46}$; therefore the compound probability of both hypothesis and event is $\frac{3}{4} \times \frac{27}{46} = \frac{81}{184}$. If the second hypothesis be true, the probability of drawing a white ball is $\frac{2}{4}$, and the probability of the hypothesis is $\frac{16}{46}$; therefore the compound probability is $\frac{2}{4} \times \frac{16}{46} = \frac{32}{148}$. If the third hypothesis be true, the chance of drawing a white ball is $\frac{1}{4}$, and the probability of the hypothesis is $\frac{3}{46}$; therefore the joint probability of the hypothesis being

true and of the event arising is $\frac{1}{4} \times \frac{3}{46} = \frac{3}{184}$. Adding together these partial probabilities, the whole probability of drawing a white ball at a future trial is $\frac{81}{184} + \frac{32}{184} + \frac{3}{184} = \frac{116}{184}$.

In like manner, the probability of drawing a black ball at a future trial is

$$\frac{1}{4} \times \frac{27}{46} + \frac{2}{4} \times \frac{16}{46} + \frac{3}{4} \times \frac{3}{46} = \frac{68}{184}.$$

And the sum of the two probabilities is 1, as it ought to be, since the ball must necessarily be white or black.

The method of proceeding which has been followed in this particular case is quite general, and applicable to all cases where it is required to compute the probabilities of events depending on causes not known *à priori*, but only inferred from experience. It may be stated generally as follows: — Let c, c', c'', c''', &c. be so many independent causes (or hypotheses), each of which may give rise to an event E; and let the probabilities of the existence of these causes be respectively h, h', h'', h''', &c., and those of the events calculated according to each hypothesis p, p', p'', p''', &c.; then the probability of the event E is $h p + h' p' + h'' p'' + h''' p''' +$ &c.

The preceding examples will suffice to give some idea of the manner in which the probability of the occurrence or failure of events depending on chance is submitted to numerical estimation; but for the methods of applying the calculus in particular cases, and especially when the formulæ involve high numbers, and the ordinary processes of arithmetic become unavailable, reference must be made to works specially devoted to the subject, a list of which is given at the end of this article.

The calculus of probabilities had its origin in the speculations of Pascal, Fermat, Huygens, and other eminent mathematicians of the 17th century. It was first applied to the solution of questions connected with games of chance; but it has since, by the researches of James Bernoulli, Montmort, Demoivre, D'Alembert, Simpson, Condorcet, Lagrange, La Place, Poisson, and others, become one of the most interesting branches of mathematics, and been applied with equal success and advantage to numerous important questions belonging to natural and political philosophy. One of its most familiar and useful applications is to the subject of annuities, assurances, reversions, and other interests depending on the average duration of human life, and the expectation of the continuance or survivorship of lives of given ages. (*See* Annuity, Expectation of Life.) Another important application is to determine the most probable *mean*, or average, of a great number of observations; and hence its utility in many cases of practical astronomy and general physics. (*See* Probable Error.) Condorcet has applied it to determine the value of testimony, the verdicts of juries, and the best mode of constituting tribunals, and of collecting votes in elections. In such applications, it is true, assumptions more or less arbitrary must be admitted, and great uncertainty will always attach to results which are influenced by human will or caprice; nevertheless, the knowledge derived from an accurate and systematic analysis of the circumstances concerned, and of the consequences of their various combinations, affords important aid in guiding our judgments, and may be of great use in the practical affairs of life.

The following are the principal works on the subject: — Montmort, *Analyse des Jeux de Hasard* (1st edit. 1708; 2d, 1713); Bernoulli, *Ars Conjectandi*, 1713; De Moivre, *Doctrine of Chances* (1st edit. 1718; 3d, greatly enlarged, 1785); Simpson, *Laws of Chance*, 1740; Condorcet, *Essai sur l'Application de l'Analyse à la Probabilité des Décisions rendues à la Pluralité des Voix*, 1785; La Place, *Théorie Analytique des Probabilités*, 3d edit. 1820; Poisson, *Recherches sur la Probabilité des Jugemens*, 1837; the article in the *Encyc. Metropol.* by Professor De Morgan, and that in the *Encyc. Brit.* by Mr. Galloway (which is published separately). For elementary works the reader may be referred to *Simpson's Laws of Chance*, and *Lacroix's Traité Elémentaire*, &c.; and for an explanation of the objects and results of the science, without mathematical investigation, to Professor De Morgan's *Essay on Probabilities, and on their Application to Life Contingencies and Insurance Offices*, in the *Cabinet Cyclopædia*.

PRO'BABLE ERROR. In Astronomy and Physics, when the value of any quantity or element, as the declination of a star, the latitude of a place, the specific gravity of a body, &c., has been determined by means of a number of independent observations, each liable to a small amount of error, the determination (in whatever way it may have been deduced from the observations) will also be liable to some uncertainty; and the *probable error* is the quantity, which is such that there is the same probability of the difference between the determination and the true absolute value of the thing to be determined exceeding or falling short of it. Thus, if twenty measurements of an angle have been made with the theodolite, and the arithmetical mean or average of the whole gives 50° 27′ 13″; and if it be an equal wager that the

error of this result (either in excess or defect) is less than 2 seconds, or greater than 2 seconds, then the probable error of the determination is 2 seconds. The method of computing the probable error, which is deduced from the theory of probability, is as follows:— Let l, l', l'', &c. be the *observed* values, h the number of observations, m the average value (*i.e.* the sum of the observed values divided by number of observations); then if we call $l-m$ the error of the observation l, and $\Sigma(l-m)^2$ the sum of the squares of the errors of all the observations, the probable error is $\cdot 674489 \times \frac{\sqrt{\Sigma(l-m)^2}}{h}$; that is, the square root of the sum of the squares of the errors, divided by the number of observations, and multiplied by the decimal ·674489.

It is frequently convenient to compute the probable error of a result from another function, which is called the *weight*. The weight is the square of the number of observations divided by *twice* the sum of the squares of the errors; and the probable error is ·476936 divided by the square root of the weight. This definition agrees with the former, for $\cdot 674489 = \cdot 476936 \times \sqrt{2}$.

PROBANG. A flexible piece of whalebone with a ball of sponge attached to its extremity, for the purpose of removing obstructions in the œsophagus.

PRO'BATE OF TESTAMENTS. In Law, the exhibiting and proving wills and testaments before the ecclesiastical judge delegated by the ordinary of the place where the party dies. It is done by granting letters testamentary to the executor under seal of the court; and such probate is evidence in questions relating to the personal estates.

PROBE. (Lat. probo, *I try.*) A surgical instrument, generally made of silver wire, rounded at one end, and pointed at the other, for the purpose of examining wounds.

PRO'BLEM. In Geometry, a proposition requiring some operation to be performed or construction to be executed; such as to bisect a line, to describe a circle passing through three given points. In algebra, a *problem* requires some unknown truth to be investigated, or discovered and demonstrated.

PROBOSCI'DIANS, *Proboscidia.* (Lat. proboscis, *a trunk.*) The name of a family of Pachydermatous Mammals, including those which have the nose prolonged into a prehensile trunk or proboscis; as the elephant and mastodon.

PROBO'SCIS, in Mammalogy, signifies the prehensile organ formed by a prolongation of the nose, of which the trunk of the elephant is an example. In Entomology, the oral instrument of the Diptera is so called, in which the ordinary trophi are replaced by an ex-articulate sheath, terminated by a pair of tumid lobes (labella), and containing one or more lancet-shaped instruments (scapella), covered by a valve. In Malacology, the same term is applied to the tongue of certain Gastropods, when it is so long as to be capable of being protruded for some distance from the mouth; in which case it is generally organized at the extremity for the purpose of boring the shells of other testacea, and of destroying by suction the soft parts of the inhabitant.

PROCEDE'NDO (or *Procedendo in Loquelâ*). A writ which lies where an action has been removed from an inferior to a superior jurisdiction, and it does not appear to the court that the suggestion on which the removal took place was sufficiently proved to send the cause back to the inferior court for further proceeding.

Procedendo ad Judicium. A writ which issues out of the court of chancery, commanding inferior courts to proceed to judgment where it has been unjustly delayed.

PROCELLA'RIA. (Lat. procella, *a storm.*) A Linnæan genus of web-footed birds, now the type of a family of the *Longipennate Palmipedes* in the system of Cuvier, characterized by the beak being hooked at the tip, with its extremity appearing as though a piece had been articulated to the rest; the nostrils are united to form a tube, which lies along the back of the upper mandible; and their feet, instead of a back toe, have merely a claw implanted in the heel. Those species in which the lower mandible is truncated belong to the true *Procellariæ.* Some smaller species, with a shorter bill, rather longer legs, and black plumage, commonly called *Storm-birds*, or *Mother Carey's chickens*, are associated under the generic name *Thalassidroma.* The *Procellariæ* range over the high seas at the greatest distance from land. Their name of *Petrel*, which is a diminutive of *Peter*, has been applied to them from their habit of walking on the waves, which they do with the assistance of their wings.

PRO'CESS, in the language of English Common Law, is used in two senses: to signify the whole proceedings in an action or prosecution; and to signify the means whereby the defendant in an action is compelled to appear in court. When actions were commenced by original writ (*see* PLEADING), original *process* was that which was founded on that writ, commencing with notice, writ of attachment, &c. *Mesne*, or intermediate process, was, properly speaking, such process as issued pending the writ on some collateral or interlocutory matter; as to summon juries or witnesses. But in popular language it was taken to signify the whole process, from the commencement of the suit, before the final process which ended it. Thus a defendant was said to be arrested on *mesne* process, *i.e.* on a writ of capias issued *pending* the suit. This was done originally when the defendant, being summoned or attached, neglected to appear or made default. In course of time, by a legal fiction, the summons and neglect were *supposed;* and the writ of capias became the commencement of the proceedings, to which the term mesne process was still, inaccurately, applied. The term mesne process is now commonly applied to the writ of summons, which is the instrument now in use for commencing personal actions. Thus the popular inaccuracy of language is retained. Final process is the writ of execution used to carry the judgment into effect. In ordinary language, the regular proceedings of every court of judicature in a suit are called its process.

PROCE'S VERBAL. In the language of French jurisprudence, an authentic written minute or report of an official act or proceeding, or statement of facts. The term is also used to signify minutes drawn up by a secretary or other officer of the proceedings of an assembly.

PROCLAMA'TION. Public notice given by the king to his subjects. (*See* KING, PRIVY COUNCIL.) The power of issuing proclamations is a branch of the king's prerogative, and vested in him alone. They have a binding force on the subject, in so far as they are grounded on and enforce the laws of the realm. They may be said to be of two sorts: the one, enforcing an actually existing law by giving it a particular application of time, place, and circumstance; the other, exercising an extraordinary power vested in the king, which until so exercised is dormant; as a proclamation to prohibit any subject from leaving the realm during a certain time. Proclamations must be under the great seal. By 31 H. 8. c. 8. it was enacted that the king's proclamations should have the force of law; an enactment which, while it subsisted, did, in effect, make a complete revolution in the government of this country. It was, however, repealed five years afterwards by 1 E. 6. c. 12. Nevertheless, in later times, it was held by crown lawyers, that the king might suspend or dispense with an existing law in favour of particular circumstances. But by 1 W. & M. stat. 2. c. 2. it is declared that no such power exists.

PROCO'NSUL. Originally an officer invested with consular command without the office. Thus, a consul sometimes had his command prolonged to him after his year of magistracy had ceased, with the title of proconsul. The provinces which at first were governed by prætors were, for the most part, subsequently put under *proconsuls* and *proprætors*, who were at first especially appointed at the Comitia Tributa; but afterwards, by the Sempronean law, entered on their provincial jurisdictions forthwith, on the expiration of their year of consulship or prætorship. The office was properly annual; but it might be prolonged, as was done in the case of Cæsar. In the time of the republic the proconsul held the military command as well as the civil jurisdiction of his province, and accordingly had about him a large staff of officers, as the lieutenants or legati, præfects, &c. But Augustus, on assuming the chief power in the state, remodelled the system by a new partition of the provinces, and by separating the civil jurisdiction, which was left the proconsul, from the military command. Under the emperors, the proconsuls and proprætors were thus distinguished; the former being appointed to the provinces under the especial superintendence of the senate, the latter to those which the emperor held.

PROCRU'STES. In Mythology, a famous robber of ancient Greece, who tortured his victims by placing them on an iron bed, which their stature was made to fit by stretching or mutilating them so as to suit its dimensions; whence the well-known metaphorical expression, the *bed of Procrustes.* He was killed by Theseus near Hermione, in Argolis. According to a recent critic (Böttiger), Procrustes, Sinis, Philyocamptes, &c. were all different names for one real or fabulous robber, derived from the different kinds of violence applied by him to travellers.

PRO'CTOR. (Lat. procurator.) In Ecclesiastical Law, he who undertakes for his fee to manage a cause in the ecclesiastical or civil court, being duly admitted under 53 G. 3. c. 127., exercising the same office which is performed by attorneys and solicitors in courts of common law and equity.

PROCTORS. In the English Universities, both at Oxford and Cambridge, two masters of arts are appointed annually to this office. Each college, in both, nominates a proctor in rotation, according to a cycle of years drawn up, on mathematical principles, to suit the number of fellows on the foundation of each. The proctors are officers of considerable importance; being, in the first place, the chief police magistrates for the time being of each

university. They, with their deputies the pro-proctors, have power not only to enforce the rules of academical discipline on the students, but also an extensive summary authority over the townspeople, according to the special privileges of the universities. They also have, in both universities, peculiar legislative authority as assistants to the heads of houses, and official votes in the election of many professors and other officers. The proctors must be masters of arts, and their standing as such, at Oxford, from four to ten years.

PRO'CURATOR. (Lat. pro, *for*, and cura, *care*.) A Roman provincial magistrate, whose office it was to manage the affairs of the revenue, and exercise a judicial authority in matters pertaining to it. Sometimes the procurator discharged the office of governor, especially in a small province, as did Pontius Pilate in Judæa; in which case, but not otherwise, he had the power of inflicting capital punishment. This magistracy did not exist under the republic, its duties being comprised under those of the prætor or proconsul, but was instituted by Augustus. They were called *Procuratores Cæsaris*, to distinguish them from the common procurator, who was merely an agent employed by private persons to manage their affairs in their absence when an action was brought against them.

PROCURATOR, *Procureur*, &c. In the Civil Jurisprudence, one who undertakes the care of any legal proceeding for another, and stands in his place by virtue of a power or *procuration* from him. A *mandatory* is said to differ from a *procurator* in that the latter acts only by virtue of an express written instrument. In France, before the revolution, the procureurs (procuratores ad lites) were officers legally empowered to carry on suits on behalf of clients. This body was abolished in 1791, and that of *avoucs* substituted in its place. The *procureurs du roi*, in France, are officers of whom one is appointed to every tribunal of arrondissement, together with a sufficient number of "substitutes."

PROCUREUR-GENERAL. The public advocate of the crown in France. Every *parlement* or *cour souveraine* had, before the Revolution, a *procureur-general* attached to it. Under the present system of judicature, one of these officers is established in every *cour royale*, for the criminal part of its proceedings; and under him an *avocat-general*, for the civil department of the court. The public accusers in the inferior courts of assize, and *premiere instance*, are termed respectively *procureurs criminels* and *procureurs du roi*. These officers are charged with the conduct of all criminal proceedings on behalf of the prosecution; and are placed under the immediate control of the minister of justice.

PRO'DIGY (of very doubtful etymology), in ordinary modern language, signifies a surprising though natural event; in contradistinction to *miracle*, which is something out of the course of nature. Among the Romans, however, any extraordinary event or appearance, to which, from insufficient acquaintance with natural history, they could not assign a cause, was termed a *prodigy*, and regarded as a supernatural event, indicative of favourable or (more generally) of unfavourable dispositions of their gods. Hence the number of recorded prodigies, many evidently false, some real but misunderstood, which Livy has inserted in his annals.

PRO'DOMUS. (Gr. προ, and δομος, *house*.) In Ancient Architecture, the portico before the entrance of the cella of a temple; the same as *pronaos*. *See* NAOS.

PRO'DUCT, in Arithmetic and Algebra, is the result of, or quantity produced by, the multiplication of one number by another, or a quantity of any kind by a number. *See* MULTIPLICATION.

PRODU'CTA. An extinct genus of fossil bivalve shells, closely allied to the living genus *Terebratula*. They only occur in the older secondary rocks.

PRO'EM. (Gr. προ ειμι, *I go before*.) A term formerly used for *preface*, which see.

PROEMPTO'SIS. (Gr. προ, *before*, and εμπιπτω, *I fall upon*.) The term applied to the lunar equation or addition of a day to prevent the new moon happening too soon; which must be effected by the addition of a day every 330 years and another every 2400. The opposite term is *metemptosis*, which is used to signify the solar equation necessary to prevent the new moon from falling a day too late, or the suppression of the bissextile every 134 years.

PROFE'SSOR. The recognized title, in all universities, of the public and authorized teachers in the various faculties. In the origin of those institutions the degrees conferred on students were, in fact, licences to commence as public teachers; and the terms master, doctor, and professor seem to have been used indifferently. But as in process of time the great body of graduates ceased, in most of them, to have any concern in public instruction, a separate body of recognized teachers gradually arose; endowed in some instances with salaries, in others paid by fees. These were the professors. But in those universities in which collegiate foundations prevailed, as in Oxford and Cambridge, these officers fell into a secondary situation. The necessary business of instruction was transacted, and still continues to be so, by the functionaries of the several colleges. The professors therefore, and the instruction which they convey by lectures, have become only auxiliaries, instead of principals, and attendance on their lectures is in few cases compulsory. On the other hand, in universities destitute or nearly so of collegiate endowments (as those of Scotland, Germany, and others founded on the German model), the professors have become at once the governing body of the university, and the sole recognized functionaries for the purpose of education.

PROFI'LE. (Fr. profil.) In Architecture, the contour of the different parts of an order.

PROFILE. In the Fine Arts, an outline of the principal parts of an object, free from all fore-shortening, showing their real projections, indentations, &c.

PRO'FIT (Fr. profit), in Political Economy, means the advantage or gain resulting to the owner of capital from its employment in industrious undertakings. It is the premium, as it were, on accumulation. Were there no profit, there would be little or no motive to save and amass; and all the vast advantages that society derives from the formation and employment of capital would be unknown. But without taking into account the security and consequence conferred on the possessors of capital or wealth, and looking only at its tangible results, profit consists of that part of the produce raised by the agency of capital employed in industrious undertakings that remains in the hands of those by whom it is employed after replacing the capital itself, or such portions of it as may have been wasted in the businesses, and every expense necessarily incurred in superintending its employment.

The *rate* of profit is the proportion which the amount of profit derived from an undertaking bears to the capital employed in it.

Thus, suppose an agriculturist employs a capital equivalent to 1000 quarters of corn, or 1000*l*., in the cultivation of a farm, and that the net surplus produce remaining to him at the end of the year, after his capital has been replaced, and he has been indemnified for the trouble of superintendence, and for every necessary expense incurred in the management of the farm, is 100 quarters, or 100*l*.; this net surplus would form the profits of the agriculturist, being to the capital by whose agency they are obtained in the ratio of 100 to 1000, or at the rate of ten per cent.

It has been shown by Dr. Smith and others, that the capital vested in different businesses yields, provided they be not subjected to any species of monopoly, about the same rate of net profit; and we shall now endeavour shortly to state the circumstances which seem to determine this rate.

In this investigation it is not necessary to inquire whether the capital engaged in certain businesses yield rent as well as profits, or profits only. The competition of the producers will always reduce profits in different businesses to what is, taking all things into account, nearly the same common level; and, as rent is in every case a surplus over and above profits, it may in this investigation be left wholly out of view. The laws by which profits are regulated in countries where the best lands only are cultivated, and no rents are paid, are in no respect different from those which regulate them in countries where cultivation has been widely extended, and where lands of superior fertility yield a high rent.

Suppose, therefore, that rent is deducted, or set aside, it follows that the whole of the remaining produce of industry must, in the first instance, be divided between capitalists and labourers; that is, between those who furnish the capital and those who furnish the manual labour made use of in the production of commodities. And hence, were taxation either unknown or constant, the proportion of the produce of industry under deduction of rent falling to the share of the capitalists could not be increased without the proportion falling to the share of the labourers being at the same time diminished, and conversely. But the share of the produce of industry falling to the capitalists includes, besides profit, the portion required to replace the capital wasted in production, and to defray the wages of superintendence. So that the rate of profit is not, as has been already stated, determined by the ratio which the share of the produce of industry that goes in the first instance to the capitalists, after every sort of outlay has been deducted, bears to the total capital employed.

Suppose, for example, that an agriculturist employs a quantity of capital of the value of 1000 quarters of corn, or 1000*l*., in cultivating a farm; that half this capital consists of seed, horses, and other instruments used in agriculture, the other half being employed in the payment of wages; and suppose that after his rent has been deducted or set aside, he has produce equivalent to 1200 quarters, or 1200*l*.; of this sum 1000 quarters, or 1000*l*., must go to replace his capital; and supposing that his taxes amount to 100 quarters, or 100*l*., it follows that 100 quarters, or 100*l*., will remain for his profits, which are consequently at the rate of ten per cent. Now, in this case — and this case is, *mutatis, mutandis*, the case of every man engaged

in business, — it is obvious that the rate of profit may be raised in three, but only in three ways; viz. 1. By industry becoming more productive; or 2. By a reduction in the rate of wages; or 3. By a reduction in the amount of taxation. And it may be reduced by the opposite circumstances; or 1. By industry becoming less productive; or 2. By a rise in the rate of wages; or 3. By a rise in the amount of taxation. Profits cannot be affected in any way not referable to one or other of these heads.

To revert to the previous example, let it be supposed, other things remaining the same, that the quantity of produce is increased, by means of the better application of the capital and labour employed, from 1200 quarters, or 1200*l.*, to 1300 quarters, or 1300*l.*; the gross amount of profits would in this case be increased from 100 quarters, or 100*l.*, to 200 quarters, or 200*l.*, and the rate of profit would be raised from 10 to 20 per cent. A similar result would be produced, other things being the same, were wages reduced from 500 quarters, or 500*l.*, to 400 quarters, or 400*l.*; and were taxation reduced from 100 quarters, or 100*l.*, to 50 quarters, or 50*l.*, the rate of profit would be raised from 10 to 15 per cent. On the other hand, if we suppose that the quantity of produce, instead of being increased, is diminished, or that wages or taxes are augmented, the gross amount of profit, and the rate of profit, will be proportionally lessened.

Had it not been for the gradually decreasing productiveness of the capital laid out on the lands, the productiveness of industry would have increased with every discovery and invention for saving labour; so that, without a corresponding increase of wages and taxes, the rate of profit would have been continually increasing. But, though improvements may materially increase the productiveness of agricultural industry for a lengthened period, the increase cannot be permanent; inasmuch as the growth of population never fails, in the end, to force recourse to inferior lands, which, of course, yield less produce in return for the same outlay. This decreasing productiveness of the capital applied to the soil has a double influence over profits; for, in the first place, it lessens the quantity of produce obtained by the outlay of capital and labour; and, in the second place, it increases the portion of that produce going to the labourer as wages. The latter must always get enough to enable him to subsist and continue his race; and though, in the event of his resorting to a lower species of food or an inferior standard of comfort, a rise in the price of raw produce may not be followed by a rise of wages, yet, speaking generally, the one is always consequent to the other. The cost of food is the main regulator of wages; and it is quite impossible to go on, for any lengthened period, by taking bad land into cultivation, or forcing the good land, making constant additions to its cost, without ultimately raising wages. Manufacturing industry, or the adaptation of matter to our use, necessarily becomes, from the influence of discoveries and inventions, more and more productive as society advances; so that the decreasing fertility of the soil is at bottom the only cause of whatever reduction in the rate of profit is to be ascribed to a decline in the productiveness of industry; and it is pretty frequently also the cause of those reductions that are occasioned by a rise in the rate of wages. The latter, it is true, is also brought about by an increased demand for labour, and by a greater prevalence of moral restraint. But a rise of wages caused by the increased cost of necessaries does not depend on contingent circumstances, or on the forethought of the labourers. It must be experienced in every country and state of society, according as it becomes more and more difficult to obtain supplies of food for an increasing population. The absolute wages of the labourer, or the quantity of necessaries and conveniences given him for his labour, may be, and indeed frequently are, diminished in the progress of society; but when cultivation is far extended, he is uniformly almost in the receipt of a larger share of the produce of his labour; so that, as has just been observed, profits are reduced in an advanced stage of society, because the quantity of produce is diminished, and because the labourers get a larger share of this diminished quantity.

The theory of Smith, as to the circumstances which determine the rate of profit, differs widely from the above. He seems to have had no idea of the important principle which shows that, despite the countervailing influence of improvements, the capitals successively applied to the land are sure, in the long run, to decrease in productiveness. And not imagining that there was any natural cause why the produce obtained by the outlay of equal amounts of capital and labour should ever be diminished, he supposed that profits were lowered through the competition of capitalists; that when capital increased, the undertakers of different businesses became anxious to encroach on each other; and that, in order to attain their object, they offered their produce at a lower price, and gave higher wages to their workmen.

But though, at first view, this theory appear sufficiently plausible, it will not bear the least examination. It is easy to see that competition cannot occasion a general fall of profits. All that competition can do, and all that it ever does, is to reduce the profits obtained in different businesses and employments to the same common level, to prevent particular individuals realizing greater or lesser profits than their neighbours. Farther than this competition cannot go. The common and average rate of profit depends not on it, but on the excess of the produce obtained by employing capital after it is replaced, along with every contingent expense. Competition cannot affect the productiveness of industry, neither can it, speaking generally, affect the rate of wages; for, such as the ordinary demand for labour is, such will be its supply, and it has no influence over taxation. It is plain, therefore, that it has nothing to do with the determination of the common and average rate of profit. It hinders individuals from getting more or less than this common rate; but it has no further effect.

Hence it appears, that that fall in the rate of profit that is usually observed to take place as society advances is not owing to an increase of capital, or to the competition consequent upon that increase, but to an inability to employ capital with the same advantage as before; resulting (1.) from a decrease in the fertility of the soils to which recourse must be had, or (2.) from a rise of wages, or (3.) from an increase of taxation. Of these causes, one may be the more powerful at one period, and another at a different period. The first not only lessens the quantity of produce raised by the outlay of capital and labour, but it also, as already seen, generally raises in the end the rate of proportional wages. It is, of course, impossible to lay down any fixed principles with respect to the influence of taxation. In the progress of society, it may increase or diminish. It has been shown that the heavy taxation of Holland, during the last century, was the principal cause of the low rate of profit in that country (*Principles of Political Economy*, 2d ed. p. 494.); and, no doubt, profits in England are sensibly affected by our taxation.

The principles already established show, 1. That so long as the productiveness of industry is undiminished, profits cannot be reduced otherwise than by a rise of wages or of taxes; 2. That so long as the rate of wages is constant, profits cannot be reduced, unless industry become less productive, or taxation be augmented; and 3. That so long as taxation remains constant, profits cannot be reduced, unless industry become less productive, or wages be raised. It is supposed, in these cases, for the sake of simplicity, that when one of the regulating principles of profit remains constant, the other two vary in the same way. But they might vary in different ways; and if so, their influence on profits would obviously depend on the extent to which the variation in the one exceeded the variation in the other. Suppose, for instance, that while the productiveness of industry remains constant, a rise of wages and a reduction of taxation are experienced; the effect of this variation will plainly depend on the rise of wages exceeding, falling short, or being identical with the reduction in the amount of taxation: if it exceed the reduction of taxation, profits will be lowered proportionally to the excess; if it be less than the reduction of taxation, profits will be proportionally raised; and if the rise of wages and the reduction of taxation be exactly equivalent, profits will, of course, undergo no change.

PROGNO'SIS. (Gr. πρό, and γινώσκω, *I know*.) An opinion respecting the progress and termination of a disease.

PRO'GRAMME. An old university term, signifying an outline of the speeches or orations to be delivered on a particular occasion; but now applied in a more extended sense to the outline of any entertainment or public ceremony.

PRO'GRESS. The state journeys of royal personages were called by this name in old English etiquette. In the reigns of Elizabeth and James they were frequent, and somewhat costly to the wealthier subjects, inasmuch as they were usually honoured with the onerous privilege of affording hospitality to royalty. The "progresses" of Queen Elizabeth form the subject of a work by Mr. Nicholl. (See also *Quart. Rev.* vol. xli.) Perhaps the most celebrated progress in English history is that of James I. from Scotland to London on his accession.

PROGRE'SSION. (Lat. progressio.) In Arithmetic, a series of numbers proceeding according to a certain order. It is arithmetical, geometrical, or harmonical.

An Arithmetical Progression is a series of numbers, increasing or decreasing by equal differences. Thus,

increasing, 1, 3, 5, 7, 9, &c.
decreasing, 18, 15, 12, 9, 6, &c.

Or, generally, $a \pm d, a \pm 2d, a \pm 3d, a \pm 4d, \pm$, &c.

Let a denote the least term,
z the greatest term,
d the common difference,
n the number of terms,
s the sum of all the terms;

then the principal properties of an arithmetical progression are expressed by the following formulæ: —

$$a = z - (n-1)\,d,\ z = a + (n-1)\,d,$$
$$d = \frac{z-a}{n-1},\ n = \frac{z-a}{d} + 1,\ s = \frac{a+z}{2}\,n;$$

and these expressions become still simpler when the first term, a, is nothing.

A Geometrical Progression is a series of numbers increasing or decreasing in a certain constant ratio; or such that the quotient of any one of them by that which immediately precedes is constantly the same. Thus,

increasing, 1, 2, 4, 8, 16, &c.
decreasing, 81, 27, 9, 3, 1, &c.

Or, generally, $a,\ r\,a,\ r^2\,a,\ r^3\,a$, &c.

$$\text{Or } a,\ \frac{a}{r},\ \frac{a}{r^2},\ \frac{a}{r^3},\ \text{\&c.};$$

where a is the first term, and r the common ratio in the one case, and $1 \div r$ the common ratio in the other.

Let a denote the least term,
z the greatest term,
r the common ratio,
n the number of terms,
s the sum of the terms;

then the principal properties of a geometrical progression are expressed as follows: —

$$a = \frac{z}{r^{n-1}},\ z = a\,r^{n-1},\quad r = \left(\frac{z}{a}\right)^{\frac{1}{n-1}},$$
$$n = \log.\frac{r\,z}{a} \div \log.\,r,\ s = \frac{r\,z - a}{r-1} = \frac{r^n - 1}{r-1}a.$$

Some of these formulæ may be more conveniently expressed in terms of s which does not enter into any one of the first four. Thus,

$$a = \frac{r-1}{r^n - 1}s;\ \text{or } a = z\,r - (r-1)\,s;\ r = \frac{s-a}{s-z}.$$

An Harmonical Progression is a series of numbers in harmonical proportion, or such that, of any three consecutive terms, the first is to the third as the difference between the first and second is to the difference between the second and third. (*See* Harmonical Proportion.) The reciprocals of an arithmetical progression form an harmonical progression. Thus, the reciprocals of the arithmetical series 1, 2, 3, 4, 5, &c. are

$$\frac{1}{1},\ \frac{1}{2},\ \frac{1}{3},\ \frac{1}{4},\ \frac{1}{5},\ \text{\&c}$$

which form an harmonical progression.

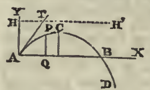
PRO'HEDRI. (Gr. προέδροι.) Certain Athenian officers chosen to superintend the proceedings in the two legislative assemblies; so called because they had the privilege of sitting in the front seats (προεδρία). The prohedri of the senate were ten in number. (*See* Prytanes.) The prohedri of the ecclesia were more in number, one being appointed from each tribe, which did not contain the prytanes for the time being. Their duties only extended to the one assembly of the people, a new set being elected each time; and one of their number was appointed epistates or president. Their employment was to propose the subject of debate to the people, and to count the votes.

PROHIBI'TION. In Law, a writ to forbid any court from proceeding in a cause then depending, on suggestion that the cause of it does not properly belong to that court. In modern times, the writ of prohibition is chiefly used where parties have been impleaded before the ecclesiastical courts. It issues properly out of the court of King's Bench; but may also be had in some cases out of the Chancery, Common Pleas, or Exchequer. It is the proper remedy where the court against which it is sued has exceeded its jurisdiction in taking cognizance of matters not properly belonging to it. It is granted on motion; but if the question of jurisdiction be doubtful, the courts direct the party suing the writ to *declare in prohibition.* This proceeding rested originally on a fiction of law. The plaintiff assumed that the writ had been granted, and brought his action against the defendant, on the supposition that he was proceeding in the case, notwithstanding the prohibition; and the merits were then tried on demurrer. But now, by 1 W. 4. c. 21., the declaration concludes with a prayer for a writ.

PRO'JECTILE (Lat. projicio, *I throw forward*), in Mechanics, is a body which, having had a motion in space impressed on it by the action of an external force, is abandoned by this force, and left to pursue its course. Thus, a stone thrown from the hand or a sling, an arrow shot from a bow, and a bullet discharged from a cannon are projectiles while they continue in motion.

Motion of Projectiles. — When a heavy body is projected from the earth, it is subject to the action of three separate and independent forces: — 1. The projectile force, or that by which it was put in motion, and in virtue of which, if no other force interfered, the body would continue for ever to move forward in a straight line with the same constant velocity. 2. The force of gravity, by which it is at every instant pulled towards the earth in a vertical line. 3. The resistance of the atmosphere, which, acting in the direction opposite to that in which the body is moving, tends at every instant to destroy its motion, or to bring it to rest.

When the projectile is a body possessing considerable density, and the motion is slow, the resistance of the air is inconsiderable, and the body describes almost the same path as if it had been projected in a vacuum; but when the velocity is great, as in the case of a cannon ball (and it is only in such cases that the theory of the motion of projectiles has any practical application), the resistance of the air becomes enormous, and causes the projectile to deviate widely from the path it would have pursued if this force had not been in action. The direct investigation of the path of a projectile in a resisting medium being a problem of the higher mathematics, and attended with very considerable difficulty, the way in which the subject can be rendered most intelligible is to proceed, in the first place, on the supposition that there is no resistance, and determine the circumstances of the motion of a body supposed to obey only the impulse by which it was projected and the force of gravity, and then to consider the resistance as a disturbing force, and find the correction that must be applied in consequence to the path determined on the previous supposition.



Motion of Projectiles in vacuo. — In order to determine the path of a projectile on the supposition that it is not resisted by the atmosphere, suppose it to be projected from the point A with a velocity a, in the direction A T; since gravity acts only in the vertical direction, it is evident that the body will move in the vertical plane passing through A T. Let A C D, therefore, be its path or trajectory in this plane; and let A X and A Y be the rectangular co-ordinates of the curve, A X being horizontal, and A Y in the direction of gravity. At the end of any given time t, let P be the place of the projectile; $x =$ A Q, its absciss; and $y =$ P Q, its ordinate: also let g be the accelerating force of gravity (= 32 feet per second), and A the angle T A X.

The body being projected in the direction of the line A T with a velocity $= a$, its velocity in the horizontal direction will continue uniform, and $= a \cos. A$. In like manner, its velocity in the vertical direction A Y, due to the projectile force, is $= a \sin. A$; and at the end of any time t the spaces passed over in those directions, if gravity did not act, would be respectively, $t\,a \cos. z$, and $t\,a \sin. A$. But the space through which a heavy body falls by the action of gravity in the time t is $\frac{1}{2} g\,t^2$; and as this is in the vertical direction, and opposite to A Y, it must be joined to the resolved part of the projectile motion in that direction, with a contrary sign. We have, therefore,

$$x = t\,a \cos. A,\ y = t\,a \sin. A - \tfrac{1}{2} g\,t^2 \ \ldots\ldots (1.)$$

On eliminating t from these two equations, and supposing the velocity a to be that which a body would acquire in falling from a height $= h$, so that $a = \sqrt{2\,g\,h}$, we obtain the following for the equation of the curve described by the projectile: —

$$y = x \tan. A - \frac{x^2}{4\,h \cos.^2 A} \ \ldots\ldots (2.)$$

This equation belongs to a parabola whose axis is vertical, or parallel to A Y. The summit of the parabola is found by differentiating the equation, and making $\frac{d\,y}{d\,x} = 0$, which gives $x = 2\,h \cos. A \sin. A$, and consequently $y = h \sin.^2 A$, for the values of x and y at that point.

In order to find the *amplitude* or *range* of the projectile, that is, the point B in which it again passes through the horizontal plane from which it was projected, we have only to suppose, in the above equation, $y = 0$. This gives

$$x = 4\,h \cos. A \sin. A = 2\,h \sin. 2\,A$$

for the value of A B; and, as the sine of an angle continues to increase to 90°, the value of A B will be greatest when A, the angle of projection, is 45°. The amplitude is then $= 2\,h$, or twice the altitude due to the initial velocity. At every other inclination there are two angles which give the same range, the one as much less than 45° as the other is greater.

The velocity v, at any point in the curve, is found by means of the differential formula $v^2 = \frac{d\,x^2 + d\,y^2}{d\,t^2}$. On differentiating the values of x and y in the equations (1.), and adding the results, we find

$$v^2 = a^2 - 2\,a\,g\,t \sin. A + g^2\,t^2.$$

Let k = the height from which a body must have fallen to acquire the velocity v, then $v^2 = 2gk$. But we have also $a^2 = 2gh$, and $t = \frac{x}{a \cos. A}$; substituting, therefore, these values in the above equation, we obtain

$$k = h - x \tan. A + \frac{x^2}{4h \cos.^2 A};$$

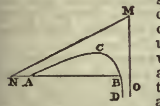
and comparing this with the value of y in equation (2.), we have ultimately $k + y = h$.

From this equation it appears that if in A Y a point H be taken, such that A H $= h$, the height from which a heavy body must fall to acquire the initial velocity, and a straight line H H′ be drawn though H parallel to the horizon, or to A X, the velocity of the projectile in the curve at any point P is equal to that which a heavy body would acquire by falling freely from the line H H′ to P. The line H H′, as is easily proved, is the directrix of the parabola; and hence all the parabolas described by bodies projected from the same point, and with the same velocities, though with different elevations, have the same directrix, and consequently their foci in the circumference of the same circle.

Thus it appears that the theory of the motion of projectiles in a vacuum is extremely simple; but, as has been already mentioned, the resistance which the air opposes to their motion, particularly when the velocity is great, is by far too considerable to be neglected; in fact, it changes entirely the form of the trajectory, and the law of motion by which it is described.

Motion of Projectiles in a resisting Medium. — When the resistance of the air is taken into account, the determination of the path described by a projectile is a problem of far greater difficulty, though still capable of rigid solution, on assuming an algebraic relation between the velocity and the resistance; but when it is considered that, in order to compute the trajectory of a resisted body, it is necessary not only to assume a law of resistance which we never can be quite sure is the true one, but also to know accurately the initial velocity of the body, together with its density, form, and dimensions, it is easy to see that no great practical advantage is likely to be obtained in any case from the theory, and that recourse must be had to experiment. The problem, however, regarded merely as a mathematical speculation, possesses considerable interest, and has been discussed by Newton in the *Principia* (Scholium, prop. 10. lib. ii.), by John Bernoulli, Dr. Brook Taylor, Hermann, Euler, and others. For the solution, see Legendre, *Exercises de Calcul Integral*, tom. i.; Poisson, *Traité de Mécanique*.

The hypothesis usually made with respect to the resistance is, that it is proportional to the square of the velocity. On this hypothesis it was shown by Newton that the trajectory has more resemblance to a hyperbola than a parabola. The two branches A C and C D are dissimilar; and the motion in the descending branch C D becomes constantly more nearly vertical and uniform, so that ultimately the body would describe a vertical line with a uniform velocity. This branch of the curve has therefore a vertical asymptote M O, to which it continually approaches. The other branch A C has likewise an asymptote, which makes an angle with the axis A B, and intersects it at a distance A N from A, depending on the initial direction and velocity of the projectile.



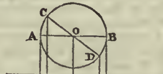
Some anomalous circumstances are observed in experiments with artillery, which are quite beyond the reach of theoretical calculation. Bullets are frequently driven to the right or left of the plane in which they were projected, as if a force acted upon them sideways as well as vertically, and in this case their path becomes a curve of double curvature. Dr. Hutton ascribes this chiefly to a whirling motion acquired by the bullet about an axis, in consequence of its friction against the sides of the piece; for this rotatory motion, combined with the progressive motion, causes each part of the ball's surface to strike the air in a direction different from what it would do if there were no such whirl. Euler, on the other hand, attributes the lateral deflection chiefly to the irregularity of the figure of the ball, and in a small degree to its rotation. Mr. Robins found the range of shot extremely uncertain, falling sometimes 200 yards short of what it did at other times, though there was no visible cause of difference in making the experiment; and Dr. Hutton states that he often experienced a difference of one fifth or one sixth of the whole range, both in the deflection to the right or left, and also in the extent of the range of cannon shot. *See* Gunnery, Resistance.

PROJECTION. In Perspective, the representation of any object on the perspective plane. *See* Perspective.

PROJECTION OF THE SPHERE. In Geography, the representation of the several parts of the surface of the sphere on a plane, according to some geometrical law by which the different points in the representation can be accurately referred to their relative positions on the sphere. It is a problem of much importance, in consequence of its application to the construction of maps, charts, planispheres, &c.

Projections are of various kinds, according to the situations in which the eye is supposed to be placed in respect of the sphere and the plane on which it is to be projected; but there are three which, by reason of the frequency of their use, are particularly deserving of attention; namely, the *orthographic*, the *stereographic*, and the *central* or *gnomonic*.

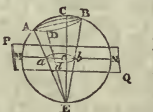
1. *Orthographic Projection.* — In this projection the eye is supposed to be at an infinite distance, and the *plane of projection*, i. e. the plane on which the representation is made, perpendicular to the direction of the rays of light, which are all parallel to each other. The laws of this projection are easily deduced. 1. Any point in space is projected by drawing a straight line from it perpendicular to the plane of projection. 2. A straight line perpendicular to the plane of projection is projected into a point. A straight line A B, parallel to the plane of projection P Q, is projected into an equal straight line $a\,b$; and a straight line CD, inclined to the plane of projection, is projected into a straight line $c\,d$, which is shorter than C D, in the proportion of the cosine of the angle of inclination to radius. 3. A plane surface perpendicular to the plane of projection is projected into a straight line. 4. A circle parallel to the plane of projection is projected into an equal circle; but a circle oblique to the plane of projection is projected into an ellipse, of which the greater axis is equal to the diameter of the circle, and the lesser axis is equal to that diameter multiplied by the cosine of the obliquity.



Orthographic projections of the sphere are usually made either on the plane of the equator, or on the plane of a meridian. When on the plane of the equator, the meridians are all represented by straight lines intersecting in the centre of the projection, and the parallels of latitude by circles whose radii are respectively equal to the cosines of the latitude. When the representation is on the plane of a meridian, the other meridians are represented by ellipses, and the parallels of latitude by straight lines parallel to the diameter of the projection. Orthographic projections of a hemisphere have this defect, that they are much crowded and distorted near the circumference of the representation, as may be inferred from the above figure; all the points in the arc A C being compressed within the line $a\,c$ (which is equal to the versed sine of the arc), while an arc at the vertex of the hemisphere is projected into a line nearly equal to itself.

The orthographic projection has a multitude of other applications. The plans and sections by which artificers execute their different constructions are orthographic projections of the things to be constructed; and a solid body may be represented in all its dimensions by orthographic projections on two planes at right angles to each other. *See* Descriptive Geometry.

2. *Stereographic Projection.* — In this projection the eye is supposed to be situated at the surface of the sphere, and the plane of projection is that of the great circle, which is every where 90 degrees from the position of the eye. Thus, let AC B E represent a sphere cut by a plane P Q passing through the centre, and perpendicular to the plane of the great circle A B E; and let E be the position of the eye in this circle. If straight lines be drawn from E to any points A D B in the opposite hemisphere, the points $a\,d\,b$ in which those lines cut the plane P Q will be the stereographic projections of A D B.



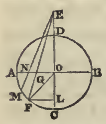
Some of the principal properties of this projection are the following: — 1. The projection of any circle on the sphere which does not pass through the eye is a circle; and circles whose planes pass through the eye are projected into straight lines. 2. The angle made on the surface of the sphere by two circles which cut each other, and the angle made by their projections, is equal. 3. Let C be the pole opposite to E, and c its projection; then any point A is projected into a point a, such that $c\,a$ is equal to half the tangent of the arc A C.

3. *Gnomonic or Central Projection.* — In this projection the eye is situated at the centre of the sphere, and the plane of projection is a plane which touches the sphere at any point assumed at pleasure. The point of contact is called the *principal point*; and the projections of all other points on the sphere are at the extremities of the tangents of the arcs intercepted between them and the principal point. As the tangents increase very rapidly when the arcs exceed 45°, and at 90° become infinite, the central projection cannot be adopted for a whole hemisphere.

The orthographic and stereographic projections were both employed by the ancient Greek astronomers for the purpose of representing the celestial sphere with all its circles on a plane. The first was called by them the *analemma*. Ptolemy wrote a treatise on this projection; and the Arabs derived from it the fundamental theorems of trigonometry. The stereographic projection appears to have been invented by Hipparchus, and was denominated by the Greek astronomers *planisphere*. The name stereographic (derived from *στερεος*, *a solid*) was given to it by the Jesuit Aguilon, because it results from the intersection of two solids, the cone and the sphere. Hipparchus and Ptolemy appear (though they do not expressly mention it) to have been acquainted with its principal property, namely, that circles on the sphere are projected into circles, which affords great facilities for the construction of maps. The second property, not less remarkable, that all circles in the projection intersect each other in angles equal to those made by the corresponding circles on the sphere, is of modern discovery, and appears to have been first demonstrated by Dr. Halley, in 1696, in No. 219. of the *Phil. Trans.*, where the discovery is attributed to Demoivre or Hooke. From the equality of the angles, it follows that any very small portion of the spherical surface and its projection are similar figures, — a property of great importance in the construction of maps, but which is not peculiar to this projection, as it belongs also to Mercator's; and numerous other relations may be assigned between the original and projected figures in which it will hold good. The gnomonic projection is also described by Ptolemy; but as the Greeks had no idea of the trigonometrical tangents, the polar distances were expressed by the ratios of the sines to the cosines of the arcs.

In constructing maps of countries, the object sought to be attained is to lay down the places in their true relative positions, and at the same time to preserve as much as possible the same scale of distances throughout. In the three projections which have been explained, equal portions of the spherical surface are represented by unequal portions of a plane surface, and the deviation from equality becomes greater from the centre to the circumference of the projection. The degrees of latitude are greatly contracted towards the circumference in the orthographic projection, and enlarged in the gnomonic, so as in both cases to produce a great distortion. Geographers have, accordingly, attempted to correct this deviation by placing the point of view at some finite distance without the sphere. This gives rise to the following, which was proposed by Lahire.

Globular Projection.—Let A C B be the hemisphere to be represented on the plane passing through the diameter A B, and let E be the position of the eye in a straight line passing through the centre O perpendicular to A B; the representation will be perfect, if the several arcs A M, M F, F C, have each the same ratio to their projections A N, N G, G O. This cannot be accomplished accurately, but the nearest approximate will be obtained by placing the point E in such a position that if F be the middle point of the arc A C, its corresponding point G is also the middle of A O. The problem, therefore, is to find a point E in C D, such that on drawing the line E F to bisect A C it shall also bisect the radius A O.



Draw F L perpendicular to O C, and join F O. It is evident that F L is half the side of the inscribed square, and G O is half the radius; therefore F L is to G O as O F or O C to O L. But $FL : GO :: LE : OE$; therefore, $LE : OE :: OC : OL$, and consequently $LO : OE :: CL : OL$; whence $OE \cdot CL = OL^2$. But $DL \cdot CL = FL^2 = OL^2$; therefore $OE = DL$, or $DE = OL$, the cosine or sine of 45°; consequently, by the trigonometrical tables, $DE = \cdot 71$, the radius being unity.

The projections which have now been explained are seldom used in delineating the features of a single country, or a small portion of the earth's surface. For this purpose it is found more convenient to employ some of the methods of development of the spherical surface explained under the term MAP.

The projection of the circles of the sphere on a plane is a problem of which the solution is easily found, either by the methods of the descriptive geometry, or by common algebra, or spherical trigonometry. Whatever be the situation of the eye, every circle on the sphere, not passing through the eye, forms the base of a cone, of which the eye is the apex; and the intersection of this cone with the plane of projection gives the curve into which the circle is projected. This curve, therefore, can be no other than a conic section, and its equation can never exceed the second degree. On forming the general equation, and assigning a particular position to the eye and the plane of projection, all the properties of the different kinds of projection are readily deduced. The subject is explained in a popular manner in *Murray's Encyclopædia of Geography* (*Introduction*), Malte Brun's *Geography*, and most other works on that science; and treated mathematically by Lambert in his *Beitrage*, &c. Berlin, 1772; by Euler in the *Petersburg Commentaries* for 1777; by Lagrange in the *Berlin Memoirs* for 1779; and by Gauss in a Memoir which is translated in the *Philosophical Magazine* for August and September, 1828.

PROJE'CTURE. In Architecture, the jutting or leaning outwards of the mouldings and other members of architecture beyond the face of a wall, column, &c.

PROLA'PSUS. (Lat.) A protrusion or falling down of a part of a viscus that is uncovered.

PROLATE SPHEROID. In Geometry, a spheroid produced by the revolution of an ellipse about its transverse diameter; so called in opposition to the *oblate* spheroid, which is produced by the revolution of the ellipse about its shorter axis.

PROLEGO'MENA. (Gr. προλεγόμενα.) In Literature, preliminary or introductory observations or dissertations prefixed to any work. The famous dissertation prefixed by D'Alembert to the *Encyclopêdie*, and the dissertations prefixed by Dugald Stewart, Playfair, Leslie, and Mackintosh to the last edition of the *Encyclopædia Britannica*, are among the best specimens of prolegomena.

PRO'LEGS, in Entomology, are the fleshy, exarticulate, pediform, often retractile organs, which assist various larvæ in walking and other motions, but which disappear in the perfect insect.

PROLE'PSIS. (Gr. προλαμβάνω, *I anticipate.*) In Rhetoric, a figure by which the speaker anticipates and answers imaginary objections, such as might be raised against the sentiments which he is urging.

PRO'LOGUE. (Gr. πρόλογος.) A piece in verse, recited before the representation of a play, and serving as an introduction to it. *See* EPILOGUE.

PROLU'SION. (Lat.) A classical word which has been adopted in a rather general sense by authors unwilling to entitle their own productions by a more ambitious designation; an essay or preparatory exercise, in which the writer tries his own strength, or throws out some preliminary remarks on a subject which he intends to treat more profoundly. The early and fugitive pieces of some poets (as the Culex and others attributed to Virgil) have been termed, by critics, their prolusions.

PROME'THEANS. A term applied to small glass tubes containing concentrated sulphuric acid, and surrounded with an inflammable mixture, which they ignite on being pressed, and thereby give instantaneous light. The term is derived from

PROME'THEUS. (From Gr. μητις, *counsel.*) According to the most ordinary form of his legend in Greek mythology, one of the Titans, who was exposed to the wrath of Jupiter on account of his having taught mortals the arts, and especially the use of fire; which he was said to have stolen from heaven, concealed in a pipe. According to another story, Prometheus was actually the creator of men; and in the *Protagoras* of Plato he is made not to have created, but to have inspired them with thought and sense. His punishment was to be chained to a rock on Caucasus, where a vulture perpetually gnawed his liver; from which he was finally rescued by Hercules. This legend has formed the subject of the grandest of all the poetical illustrations of Greek supernatural belief, the *Prometheus Bound* of Æschylus. Many have recognized in the indomitable resolution of this suffering Titan, and his stern endurance of the evils inflicted on him by a power with which he had vainly warred for supremacy, the prototype of the arch-fiend of Milton. Others have sought for a recondite analogy, and discovered in the tortures endured by Prometheus as a sacrifice for mankind, whom he had benefited, a foreshadowing of the great mystery of Christianity.

PRO'MISSORY NOTE. A note or writing by which an individual, or number of individuals, promise or engage to undertake or perform some specified act. In ordinary language, however, it is applied to engagements to pay certain specified sums of money at certain dates. Such documents, if drawn on proper stamps, are legal negotiable instruments that enjoy the same privileges as bills.

PRO'MONTORY. (Lat. pro, and mons, *a mountain.*) In Geography, a point of land, whether high or low is indifferent, projecting into the sea. *See* CAPE.

PROMU'SCIS. The name of the suctorious organ of the Hemipterous insects, formed by the union of the two jaws (*maxillæ*) to the lower lip, which they embrace; thus forming a jointed organ, containing four long capillary lancets and a short tongue.

PRONA'OS. (Gr. προ, and ναος, *a temple.*) In Architecture, the front porch of a temple. *See* NAOS.

PRONA'TOR MUSCLES. Those which are used in turning the palm of the hand downwards.

PRO'NOUNS. In Grammar, parts of speech which are used in the stead of nouns, to avoid needless or inconvenient specification. Pronouns are divided into *substantive* or *personal*, and *adjective*; the latter including

possessive, *demonstrative*, *relative*, *indefinite*, and *interrogative* pronouns.

PROOF. (From the verb *to prove.*) In Engraving, an impression taken from an engraving to prove the state of it during the progress of executing it; also one taken before the insertion of the letters are engraved on the plate.

PROOF. In Printing, an impression on which the errors and mistakes are marked for the purpose of being corrected. Proofs are,— first proof, which is the impression taken with all the errors of workmanship. After, it is read by the copy, and the errors corrected, which if not many, and carefully done, another impression is printed with more care, to send to the author; this is termed a clean proof. On it he makes his corrections and alterations: when those are altered in the types, another proof is printed, and read over carefully, previously to the whole number being printed off; this is called the press proof.

PROOF. *See* EVIDENCE.

PROOF SPIRIT. A mixture of equal weights of absolute alcohol and water; the specific gravity of such a mixture is 0·917; but the density of the proof spirit of commerce is 0·930.

PROPÆDEU'TICS. (Gr. προ, and παιδευω, *I instruct.*) A term used by German writers to signify the preliminary learning connected with any art or science: that in which it is necessary to be instructed, in order to study with advantage the art or science itself.

PROPAGA'NDA. The name given to an association, or, as it is termed, the congregation *De propagandâ Fide*, established at Rome by Gregory XV. in 1622, for diffusing a knowledge of Christianity throughout the world. It is a committee of cardinals and special agents of the pope, under whose presidency it meets every week. Its duties are, the superintendence and assistance of missionaries in all parts of the globe, the maintenance of recent converts, the publication of religious works in foreign languages, &c. Derived from this celebrated society, the name *propaganda* is applied in modern political language as a term of reproach to secret associations for the spread of opinions and principles which are viewed by most governments with horror and aversion.

PROPAGA'TION OF PLANTS. The greater number of plants are propagated naturally by means of seeds; but, in addition to these, many plants are extended over the surface on which they take root by the production of runners or lateral shoots, which spread along the surface, and root at the joints or buds, from which they send up new plants; by suckers or side shoots from the roots; and by various other natural means. Artificially, plants are propagated by seed, by runners, suckers, offsets, dividing the tubers, layers, cuttings, grafting, budding, inarching, &c. Seeds are gathered when mature, and sown on recently stirred soil, and covered to different depths, according to the size of the seed, the nature of the soil and situation, and other circumstances. The plants formed by runners are separated from the parent plant by cutting through the runner, and removing the young plant, in order to plant it elsewhere. Suckers, slips, or side shoots from the roots, are separated from the parent plant by being slipped down, or cut off, so as to carry with them a portion of fibrous roots; and they are afterwards planted in suitable soil, &c. Offsets are small bulbs which are produced round the base of larger ones, and, being taken off and planted, become plants. Tubers are underground stems, containing leaf-buds; and these may be separated and planted entire, or cut into as many pieces as there are buds, in either of which cases new plants will be formed. Layers are branches or shoots of either woody or herbaceous plants, which are bent down, and a portion of their length buried a few inches in the soil; that portion having been previously wounded by cutting, bruising, or twisting, which, by checking the descent of the sap, gives rise, after a certain period, to the production of roots. After these roots are formed, the portion of the layer which has produced them is separated from the main stock or parent plant, and planted by itself. Cuttings are portions of shoots, either of ligneous or herbaceous plants; and they are made of the young shoots with the leaves on, or of the ripened wood either with or without its leaves; and after they have, either in a herbaceous state with the leaves on, or with the wood mature and with or without the leaves, been properly prepared and planted, they form roots at their lower extremity, each cutting becoming a perfect plant. In general, cuttings should be taken from those shoots of a plant which are nearest the soil; because, from the moisture and shade there, such shoots are more predisposed to emit roots than those on the upper part of the plant. The young or last-formed shoots are to be taken in preference to such as are older, as containing more perfect buds in an undeveloped state, and a bark more easily permeable by roots; and the cutting is to be prepared by cutting its lower extremity across at a joint, the lenticells or root-buds being there most abundant. When the cutting is planted, the principal part of the art consists in making it quite firm at the lower extremity, so as completely to exclude the air from the wounded section. Cuttings emit roots at this section, either in consequence of the action of the accumulated sap in the cutting, as in the case of the ripened wood in deciduous trees and shrubs; or in consequence of the joint action of the accumulated sap and of the leaves, as in the case of cuttings of soft wood with the leaves on, and in a living state. A few plants are propagated by cuttings of the leaves, the petiole of the leaf being slipped off from the parent plant, and probably containing the latent embryos of buds. Grafting and budding are processes which have been already explained. (See these words.) Inarching may be described as a species of grafting, in which the scion is not separated from the parent plant till it has become united with the stock.

PRO'PEDS, *Prcpedes.* The name given by Kirby to the soft, fleshy, inarticulate, pediform appendages of certain larvæ, placed behind the true feet, and disappearing in the mature insects.

PRO'PER. In Heraldry, any object represented of its natural colour is so termed.

PRO'PERTY. In Logic, a predicable which denotes something essentially conjoined to the essence of the species. There are enumerated in books on logic four kinds of property, which are termed "universal, but not peculiar;" "peculiar, but not universal;" "universal and peculiar;" "universal and peculiar, but not at every time." The last kind is evidently more properly designated as Accident. *See* LOGIC, PREDICABLE.

PROPERTY, RIGHT OF. *See* RIGHT OF PROPERTY.

PRO'PHETS. (Gr. προ, *before*, and φημι, *I speak.*) A title given in the Scriptures to persons inspired, or endowed with the capacity to predict future events. The first to whom it is applied is Abraham; and we hear, in the same extended sense, of companies of prophets, persons who were employed in the study or exposition of the divine law, in which case it does not necessarily imply the power of predicting future events. In its more strict signification, the term prophet is given to Elijah, Elisha, and others, who did not commit their prophecies to writing, but whose inspiration is attested in the historical books of the Old Testament, and to the sixteen whose books are collected under the subdivisions of the greater and the lesser. Jonah, the earliest, lived about 800 B. C.; and Malachi, the latest, about 400 B. C.

PROPHYLA'CTIC. (Gr. προφυλασσω, *I defend.*) Means used to prevent disease.

PROPO'RTION (Lat. proportio), in Arithmetic and Geometry, is the equality or similitude of ratios; four numbers or magnitudes being said to be proportional, or in proportion, when the ratio of the first to the second is the same as the ratio of the third to the fourth, or when the first divided by the second gives the same quotient as the third divided by the fourth.

The definition of proportion has given rise to much controversy among writers on the elements of geometry. Euclid's celebrated definition in the fifth book, whatever may be said in favour of its ingenuity and exactness, is found by experience to be much too complicated and refined to be understood by beginners; and accordingly many attempts have been made to substitute for it one more intelligible; but, on account of the difficulty of defining the term *ratio* in such a manner as to include incommensurable quantities, none of these attempts can be said to have been perfectly successful. This imperfection, however, must be understood as belonging merely to the metaphysical accuracy of the definition, for many of the treatises which have been composed with the view of superseding Euclid's have all the simplicity and elegance which can be desired. On this subject the reader may consult *Barrow's Mathematical Lectures;* the notes to *Playfair's Euclid; Camerer's Euclid*, Berlin, 1825; De Morgan, *On the Connexion of Number and Magnitude*, 1836; and the art. "Proportion" in the *Penny Cyc.*

Proportion is *continual* or *discrete*, *direct* or *inverse*. It is continual when every two adjacent terms have the same ratio, or when the consequent of one ratio is the antecedent of the next following: thus, 2, 4, 8, 16, &c., are numbers in continual proportion, for the ratio of 2 to 4 is the same as that of 4 to 8, of 8 to 16, &c. *Discrete* proportion is when the antecedent of one ratio is different from the consequent of the former; thus, 2, 3, 4, 6. The terms *direct* and *inverse* have reference to arithmetical questions in what is denominated the Rule of Three, and which in their enunciation include four numbers, two of which are of one kind and two of another, and moreover each number of the second kind intimately connected with one of the numbers of the first kind by the nature of the question. Now, when the four numbers are written in the form of a proportion, if the antecedents of the two ratios are the related numbers, the proportion is said to be direct; but if the antecedent of the first ratio is the number connected with the consequent of the second, the proportion is inverse. For example, let the question be this; If 8 yards cost 12 shillings,

what is the price of 20 yards? The answer is 30 shillings. Now, in this question, the numbers 8 and 20 are of one kind, namely, yards; and the two others, 12 and 30, are of the same kind, shillings. The numbers form the proportion 8 : 20 : : 12 : 30; and the numbers 8 and 12 (the antecedents of the ratios) are related to each other, and also 20 and 30; 12 shillings being the price of 8 yards, and 30 the price of 20. The proportion is therefore *direct*. But if the question were to find in how many days 4 men will do a piece of work, supposing 6 men can do it in 10 days, the related numbers would be differently placed; for the answer being 15 days, the four numbers written as proportionals must stand thus, 4 : 6 : : 10 : 15; and as the numbers 4 and 15 are here the related numbers, or the antecedent of the first ratio is related to the consequent of the second, the proportion is *inverse*. This is also called *reciprocal* proportion; for if one of the ratios be formed of the reciprocals of the given numbers instead of the numbers themselves, the related numbers would stand as in direct proportion; thus, $\frac{1}{4} : \frac{1}{6} : : 10 : 15$; or $6 : 4 : : \frac{1}{10} : \frac{1}{15}$.

It is a property of proportional numbers, derived immediately from the definition, that the product of the first and fourth terms is equal to the product of the second and third. Hence, when three terms of a proportion are given, the fourth can be found. This is the object of all questions in the Rule of Three.

The preceding remarks apply exclusively to *geometrical* proportion; that is to say, when the proportion consists in the equality of ratios. Writers on arithmetic also mention *arithmetical* proportion, and *harmonical* proportion, for which see the respective terms.

Proportion. In the Fine Arts, the most proper relation of the measure of parts to each other and to the whole. The Greeks used the word συμμετρια (symmetry), to express this idea. In many instances, proportion may be considered almost synonymous with fitness, though there is a distinction between them; since every form susceptible of proportion may be considered either with respect to its whole as connected with the end designed, or with respect to the relation of the several parts to the end. In the first case, fitness is the thing considered; in the second, proportion. Fitness, therefore, expresses the general relation of means to an end, and proportion the proper relation of parts to an end. It is hence needless to dwell on the intimate connection that exists between beauty and proportion, in all complex forms. Payne Knight, *in his Inquiry into the Principles of Taste*, has asserted that in many productions of art "symmetry is the result of arbitrary connection." It would be very easy to show the absurdity of this assertion, if we considered it worth the space.

PROPORTIONAL COMPASSES. Compasses with two pairs of opposite legs, by which distances are enlarged or diminished in any proportion.

PROPORTIONAL SCALES. *See* Scales.

PROPORTIONALS. The terms of a proportion; of these the first and last are the *extremes*, and the intermediate the *means*, or the *mean* when the proportion consists of only three terms. *See* Proportion.

PROPORTIONS, DEFINITE. In Chemistry. *See* Affinity.

PROPOSI'TION, in Logic, is defined "a sentence indicative;" *i. e.* a sentence which affirms or denies. Thus, sentences in the form of command or question are excluded from the character of propositions. Logical propositions are said to be divided, first, according to substance, into categorical and hypothetical; secondly, according to quality, into affirmative and negative; thirdly, according to quantity, into universal and particular. 1. A categorical proposition is where the sentence affirms or denies absolutely, as "man is mortal." A hypothetical proposition is defined to be two or more categoricals united by a conjunction, as "if Caius is man, he is mortal." There are several sorts of hypothetical propositions; conditional, disjunctive, causal, &c. 2. An affirmative proposition is one whose copula (or conjunction) is affirmative, as "man is mortal;" a negative proposition has a negative copula, as "man is not immortal." 3. An universal proposition is when the predicate is said of the whole of the subject, as "all men are mortal," "Caius is mortal;" a particular, when it is said of part of the subject only, as "some men are rich." To these two species may be added the indefinite proposition, when the subject has no sign of universality or particularity, or is a singular noun, which is either universal or particular according to the matter. The matter of a proposition is said to be either necessary, impossible, or contingent; and if the matter of an indefinite proposition be either of the former, it is equivalent to an universal; if the last, to a particular: *e.g.* "birds fly," *i. e.* all birds — universal. "No birds are quadrupeds;" here the matter is impossible, and the proposition universal. "Birds sing," *i. e.* some birds — particular.

The fourfold division of propositions according to quality and quantity is denoted by arbitrary signs; *e.g.* A stands for an universal affirmative, in the logic used at Oxford; E for an universal negative; I for a particular affirmative; O for a particular negative.

A categorical proposition is composed of two terms united by a copula. (*See* Term, Copula.) The first term, *i. e.* that of which the other is affirmed or denied, is the subject; the other (that which is affirmed or denied respecting the first) the predicate. In the collocation of our language, the subject usually, but not invariably, precedes the predicate. Thus, "Diana of the Ephesians (subject) is great" (predicate), is transposed into "Great is Diana of the Ephesians." In some languages, as Greek and Latin, the latter form of collocation is not less natural or usual than the former. When the subject of a proposition is a common term (*see* Term) it is said to be "distributed," when the universal sign (all, no, every, &c.) is prefixed, and the proposition consequently universal. The predicate is said to be "distributed" in all negative and no affirmative propositions, inasmuch as a negative proposition denies that any part of the predicate agrees with the subject, whereas an affirmative can *never* assert that every part of the predicate agrees with the subject; *i. e.* can never do so necessarily, by the logical force of the proposition, although it may undoubtedly happen that the predicate agrees with the subject and with nothing else: *e. g.* "Cæsar was the first Roman emperor." Two propositions are said to be opposed, when, having the same subject or predicate, they differ in quantity, in quality, or in both. The two universals (A and E) are termed *contraries* to each other; the two particulars (I and O) *sub-contraries;* the universals and particulars (A and E, I and O) *subalterns;* A and O, or E and I (those which differ both in quantity and quality), *contradictories*. A proposition is said to be converted when its terms are transposed; *i. e.* when the subject is made the predicate, and the predicate the subject. *See* Conversion of Propositions.

Proposition. In Mathematics, a theorem proposed to be demonstrated, or a problem in which something is proposed to be done.

PROPRÆ'TOR. A Roman magistrate, bearing the same relation to the prætor that the proconsul did to the consul. (*See* Proconsul.) Under the emperors, proprætors, as distinguished from proconsuls, were appointed as governors to the imperial provinces, the latter being the servants of the senate.

PROPYLÆ'UM. (Gr. προπυλαιον.) In Ancient Architecture, the vestibule of a house. The vestibules or porticos at Athens, leading to the Acropolis, were thus denominated.

PRO RE NATA. (Lat. *according as occasion may require.*) A term commonly used in medical prescriptions.

PROROGA'TION. *See* Parliament.

PROSCE'NIUM. (Gr. προ, *before*, and σκηνη, *a scene.*) In Architecture, the frontispiece or part in a theatre where the drop scene separates the stage from the audience, and beyond the orchestra. In the ancient theatres it comprised the whole of the stage.

PROSCRI'PTION. (Lat. proscribere, *to proscribe, outlaw, or doom to death; to confiscate one's property.*) The most vindictive species of proscription was that introduced by Sylla when he wrested Rome from the hands of the Marian faction. It consisted in making out a list of persons supposed to be obnoxious to the state, and getting a sentence of condemnation passed against them, which made it unlawful to harbour a proscribed person. By these measures thousands of citizens perished in the civil wars of Rome. The most celebrated proscription was that of the triumvirs, Octavius, Antony, and Lepidus, in which Cicero was slain.

PROSE. (Lat. prorsa oratio; from prorsus, adv., *direct* or *straightforward.*) In Literature, all language not in verse. Prose diction, to be good, or even admissible, in ordinary criticism, must be conformable to the rules of composition as to style, cadence, &c.

PRO'SELYTE. (Gr. προσηλυτος, *one who arrives as a stranger.*) A term in use among the Jews after their connection with the Greeks, and applied to such foreigners as embraced their religion. These they divided, according to the common opinion, into two classes; distinguished by the terms proselytes of the gate, and proselytes of righteousness. Of these the former were such as merely renounced idolatry, and believed in and worshipped the true God, observing the precepts of the natural law, and, from being admitted within the first gate of the temple, received this appellation. The latter class were those who submitted to circumcision, and in every other respect conformed entirely to the customs of the Jewish people. Dr. Burton, however, it must be admitted, thinks this distinction unfounded. (*Lectures on the Eccl. History of the First Three Centuries*, l. iii.)

PRO'SENCHYMA. (Gr. προσεγχεω, *I pour still more upon.*) Cellular tissue, the cellules of which taper to each end, and consequently overlap each other at their extremities. It is the first approach on the part of cellular tissue to the condition of woody tissue.

PRO'SERPINE. The Latin form of Persephone, the

name of a Grecian goddess, sprung from Jupiter and Ceres. She was stolen from her mother by Pluto, who, enamoured of her beauty, carried her off from the plains of Enna in Sicily, while sporting with her companions, to the infernal regions, where she became his queen. The wanderings of Ceres in search of her daughter were much celebrated by the ancient poets. When she at last discovered the place of her concealment, a compromise was entered into, by which Proserpine was allowed to spend two thirds of the year with her parents and the rest with Pluto in his empire.

PRO'SODY. (Gr. προς, *to*, and ωδη, *song;* signifying, literally, a guide or assistance to versification.) The science which treats of quantity, accent, and the laws of harmony, both in metrical and prose composition. In the Greek and Latin languages every syllable had its determinate value or quantity, and verses were constructed by systems of recurring feet, each foot containing a definite number of syllables possessing a certain quantity and arrangement. (*See* FOOT.) The versification of modern European languages, in general, is constructed simply by accent and number of syllables. They have, therefore, no prosody strictly so called. The Germans, however, have laboured to subject their language to the ancient metrical system, but with indifferent success.

PROSOPO'GRAPHY. (Gr. προσωπον, *figure* or *person*, and γραφω, *I describe.*) In Rhetoric, a word used by some critical writers to signify the description of animated objects. Of this figure the portraits of the horse and the leviathan in the book of Job are well known and beautiful examples.

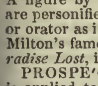
PROSOPOPŒ'IA. (Gr. προσωπον, and ποιεω, *I make.*) A figure by which inanimate objects, or abstract ideas, are personified, and addressed or represented by the poet or orator as if endowed with human shape or sentiments. Milton's famous digression of Sin and Death, in the *Paradise Lost*, is at once a prosopopœia, and an allegory.

PROSPE'CTUS (Lat.), in its most extended sense, is applied to the outline of any plan or proposal submitted for public approbation; but it is most usually confined to literary undertakings, in which it signifies an outline or sketch of the plan or design of a work, together with such other circumstances connected with the publication, &c., as it may be thought desirable to enlarge upon or make known.

PRO'STATE GLAND. In Comparative Anatomy, the prostate gland retains its single compact form in most of the Quadrumana; but is bifid in the Ruminantia; in the Rodentia and Insectivora it is resolved into numerous slender elongated cæcal tubes; in the mole it is remarkable for its periodical increase of size.

PRO'STATES. (Gr.) The name given to the guardians of the foreign settlers at Athens, whose business it was to represent them in courts of law, and protect them from injury.

PRO'STHAPHE'RESIS. (Gr. προσθεν, and αφαιρεσις, *subtraction.*) A term used by the older writers on astronomy to signify the difference between the true and mean motion, or the true and mean place of a planet, or the quantity which must be taken from or added to the mean anomaly, in order to get the true anomaly.



Let P (or P') be the place of a planet in its orbit, S the sun, C the centre, and A the perihelion of the orbit; the angle A S P is the true anomaly, A C P is the mean anomaly; and the difference between A S P and A C P is S P C, which is the prosthapheresis. If A C P be less than a right angle, S P C must be added to A C P in order to get the true anomaly; but if it be greater than a right angle, the angle S P C must be deducted. The angle S P C is called by modern writers the equation of the *centre*, or equation of the orbit.

PRO'STHESIS. (Gr. προς, and τιθημι, *I place.*) A figure of grammar by which one or more letters are added to the commencement of a word; as in the common English participles, *be*loved, *be*reft, &c. *See* METAPLASM.

PRO'STYLE, or PROSTYLOS. (Gr. προ, *before*, and στυλος, *a column.*) In Architecture, a temple or other building with columns in its front face.

PRO'TASIS. (Gr. προτασις, from προτεινω, *I stretch or put forth.*) In Grammar and Rhetoric, every properly constructed period (*see* PERIOD) is said to be naturally divisible into two parts; of which the first is termed protasis, the second apodosis. In the ancient drama, the protasis was the exposition, usually contained in the first part of the piece, either by way of soliloquy or dialogue, serving to make known the characters and the plot to the audience.

PROTEA'CEÆ. (Protea, one of the genera.) A natural order of arborescent, rigid, useless Exogens, inhabiting the hotter parts of the world, and found in dry, sterile, stony, exposed places, especially near to the sea coast. They are known from *Elæagnaceæ* by the woody texture of their leaves; by the irregular calyxes having a valvate æstivation, with the stamens placed upon the lobes; and by the dehiscent fruit. The genera *Banksia*, *Dryandra*, *Protea*, and *Grevillea*, are cultivated for the sake of their beautiful foliage and flowers. The seeds of *Gucvina* are sold in Chili for the same use as hazel nuts with us. One of the larger timber trees of New Zealand is the *Knightia excelsa*, a plant of this order.

PROTE'CTOR. In English History, a title which has been three times assumed by daring statesmen: — 1. Richard, duke of York, in 1453, was appointed by parliament protector during pleasure. 2. The duke of Somerset, being constituted one of Henry VIII.'s sixteen executors, obtained a patent from the young king, Edward VI., in 1548, constituting him protector, with the assistance of the other fifteen as councillors; but he only enjoyed this dignity a few months, and his loss of it was soon followed by his death. 3. Cromwell took the title of lord protector of the commonwealth of England, Scotland, and Ireland, on the 12th Dec. 1653, when the "Barebones Parliament" resigned its authority into his hand. His son Richard succeeded him in his title and authority, but was never formally installed protector.

PRO'TEST. In Parliamentary Law, is a privilege peculiar to the members of the upper house of parliament of entering (by leave of the house always presumed) their dissent from a motion or resolution agreed to by a majority of the house, together with their reasons for dissenting. The paper embodying these reasons of dissent is called a protest, and is entered on the journals. Protests, with the reasons, were first set down, according to Lord Clarendon, in 1641. *See* PARLIAMENT.

PRO'TESTANTS. A general name applied to the various denominations of Christians which have sprung from the adoption of the principles of the Reformation in the 16th century. The term was assumed, in the first instance, by the reformers of North Germany, who, in the year 1529, formally protested against a decree of the imperial diet held at Spires, which ordained that the question between the parties should remain unsettled, some restrictions being laid upon the progress of the new opinions, until the calling of a general council, the time of which was left uncertain. The Protestants accordingly asserted that the decree was unfavourable and unjust to their party, and claimed the immediate summons of a lawful council, which they knew it was the interest of the papacy, under the circumstances, to delay. In the early period of the Reformation, the principal reformed churches were two, those of the followers of Luther and of Calvin, the partisans of Zuingli having become nearly identified with the latter. Since that time the number of subdivisions upon every point of doctrine and discipline has been infinite. The general bond of union, however, among all, continues to this day to be the assertion of private judgment, and rejection of any infallible head of the church, or ultimate authority in pope or council. We believe, also, that no Protestant church has ever relapsed into any one of the prominent results of the Romish system — such as the doctrine of the seven sacraments, of transubstantiation, or of purgatory, the celibacy of the clergy, or veneration of images or relics.

There are, however, two lines of argument upon which these principles are maintained, the respective assumption of which seems to constitute the strongest line of distinction among Protestants. The first is that to which the German and Swiss reformers most generally leaned, which considers the Bible to contain within itself so complete a repository of divine truths as to be its own interpreter, as well as the evidence of its own authenticity and inspiration. The English reformers, on the other hand, endeavoured to base their doctrines upon the practice of the first three centuries, and appealed therein to similar principles with the Roman church, which they maintained to be corrupt, not in its origin, but in its growth.

PRO'TEUS. A marine deity of the Greeks, celebrated for his gift of divination, and the power of changing his form, by which means he eluded those who resorted to him for information.

PRO'TEUS. In Zoology, this name was originally and very aptly applied to a genus of Infusories, which, during life, never for a single minute maintain the same form; this peculiarity is strikingly manifested, as in the common species called *Proteus diffluens*. The term was subsequently used by Laurenti to designate a singular amphibious reptile, peculiar to certain subterranean waters in Carniola, and which, like the American siren, retains the external gills, together with internal lungs or air-bags throughout life.

PROTHO'NOTARY. (Lat. proto-notarius, or *first notary.*) A title originally of the Byzantine empire. The Apostolical prothonotaries of the Papal court are officers having precedence of the other notaries or secretaries of the Roman chancery; the papal "notaries participant" rank after bishops, but before abbots. In England, officers in the courts of King's Bench and Common Pleas had this title, until the recent changes in those courts.

PROTHO'RAX. (Gr. προ, *before*, and θωραξ, *a shield.*)

In Entomology, signifies the first segment of the thorax in insects; by Kirby the term is restricted to the upper part only, or shield of that segment.

PROTHY'RIDES. (Gr. προ, and θυρα, *a door.*) *See* ANCONES.

PRO'THYRUM. (Gr. προ, and θυρα.) In Architecture, a porch before the outer door of a house.

PRO'TOCOL. (From the Latin protocollum: a word derived from the Greek πρωτος, *first*, and κολλα, *glue;* but the etymological signification attached to this derivation seems unknown.) The word protocol, in the French language, signifies the formulæ or technical words of legal instruments; in Germany, it has been used to denote the minutes or rough draught of an instrument or transaction. It is in the latter sense that the word has been borrowed by diplomacy, in which it signifies the original copy of any dispatch, treaty, or other document.

PRO'TOTYPE. (Gr. πρωτος, *first*, and τυπος, *a mark.*) In the Fine Arts, the original pattern or model of a thing whereon are founded principles of imitation.

PROTOZO'A. (Gr. πρωτος, and ζωον, *animal.*) A name synonymous with acrita and oozoa, and applied to the simplest animals, or those which stand, as it were, on the first step of organization.

PROTRA'CTOR. A mathematical instrument for laying down angles on paper, used in surveying, plotting, &c.

In its simplest form, the protractor consists merely of a semicircular limb of metal, divided into 180°, and subtended by a diameter, in the middle of which is a notch to mark the position of the centre. On placing this notch over the angular point, and laying the diameter along a given straight line, an angle of any number of degrees may be made by marking the point on the paper which coincides with the given degree on the limb, and joining this point with the centre, when the instrument is removed. The protractor is rendered more commodious by transferring the divisions to the edge of a parallel ruler.

When a survey is to be plotted on a large scale, and it becomes necessary, in consequence, to lay down the angles with considerable precision, a more complex apparatus is required. The most approved form of the protractor may be described as follows: — It consists of an entire circle, connected with its centre by four radial bars. The centre of the metal is removed, and a circular disk of glass fixed in its place, on which are drawn two lines crossing each other at right angles, the point of intersection denoting the centre of the protractor. Round the centre, and concentric with the circle, is fitted a collar carrying two arms, one of which has a vernier at its extremity adapted to the divided circle; and the other a milled head, which turns a pinion working in a toothed rack round the exterior edge of the instrument. The rack and pinion give motion to the arms, which can thus be turned quite round the circle, and set the vernier to any angle that may be required. Each of the two arms is prolonged beyond the edge of the protractor, and carries a fine steel pricker, which is pressed down when the instrument is placed in its required position, and makes a small puncture in the paper. It is essential that the points of the two prickers, and the centre of the instrument, be accurately in the same straight line. (*Simms on Mathematical Instruments.*)

In Anatomy, the muscles which draw forwards a part are termed *protractors.*

PRO'VERB. (Lat. proverbium.) A familiar saying, which has been variously defined. In point of form, there are two species of proverbs; one containing a maxim directly expressed in a concise and familiar style; the other, in which a maxim is expressed metaphorically, *e.g.* "honesty is the best policy," or, rather, allegorically, *e.g.* "strike, while the iron is hot." In point of substance, proverbs are for the most part rules of moral, or, still more properly, of prudential, conduct.

In dramatic literature, chiefly French, the term has been applied to short pieces, in which some proverb or popular saying is taken as the foundation of the plot. They originated in the fondness of the higher classes of France for private theatricals, which became a sort of passion about the middle of the last century. Carmantelli was the most successful writer of proverbs at the time of their highest popularity. Those of M. Theodore Leclercq, at the present time, have met with considerable success.

PROVERBS, THE, OF SOLOMON. One of the canonical books of the Old Testament. According to the arrangement in its present shape, the first nine books form a species of introduction; those from the tenth to the twenty-fourth contain the proverbs of Solomon, properly so called; and the remainder furnishes a kind of appendix; including the thirtieth and thirty-first, which contain the proverbs of Agur, the son of Jakeh, and of king Lemuel.

PROVI'NCIA. Those countries were called by the Romans provinces which, having been reduced under their power, were subjected to government by magistrates sent from Rome. The laws of a province were generally settled by ten commissioners, dispatched from Rome in conjunction with the victorious general. In its modern acceptation, province signifies a grand division of a kingdom or state, comprising several cities, towns, &c. all under the same government, and usually distinguished by the extent either of the civil or ecclesiastical jurisdiction.

PROVI'SIONS, in the Navy, daily, 1 lb. of biscuit, 1 oz. of cocoa, ¼ oz. of tea, ½ of an imperial pint of spirits, or 1 imperial pint of wine, ¾ lb. of beef with ¾ lb. of flour, and ¾ lb. of pork with ½ a pint of peas on alternate days, or 1 lb. of fresh meat with 9 oz. of vegetables. Part of the flour may be exchanged for suet, currants and raisins; 1 pint of oatmeal, and 10 oz. of sugar a week. After ten days of salt provisions, an allowance of lemonade.

PROVI'SO. In Law, a condition inserted in a deed on which its validity depends, commencing usually with the words "provided that;" as also in acts of parliament.

PROVI'SOR. The title, in the ancient French Universities, of an officer charged with the management of their external affairs, both spiritual and temporal, and to a certain extent with their discipline also. The provisor of the Sorbonne was an officer of high importance among the clergy. The principals of Napoleon's lyceum had the title of provisors, and the modern royal colleges retain it for the same functionary.

PRO'VOST (contracted from Lat. præpositus, *placed over.*) The title of the chief municipal magistrates of Scotland, equivalent to mayor in England. The chief magistrates of Edinburgh and Glasgow are styled *Lord Provost.*

PROVOST OF A UNIVERSITY. See UNIVERSITY.

PRO'XENE. (Gr. προξενος.) In Grecian Antiquities, officers at Sparta who had the charge of superintending strangers. (Herodot. vi.) In the flourishing time of the Grecian republics, wealthy and distinguished men of particular states seem to have accounted it an honour to act as protectors of the citizens of foreign commonwealths: thus, Alcibiades was *proxenus* of the Spartans at Athens.

PRO'XIMATE PRINCIPLES. Distinct compounds which exist ready formed in animals and vegetables, such as albumen, gelatine, fat, &c., in the former; and sugar, gum, starch, resins, &c., in the latter, which are so called, without reference to their ultimate composition.

PRO'XY. (Lat. proximus.) In Parliamentary Law, every peer, spiritual or temporal, can (by license, supposed to be obtained from the king) constitute another lord of parliament, of the same order with himself, his proxy, to vote for him in his absence. Proxies cannot be used when the house is in committee, nor can a proxy sign a protest. By an order of 2 C. 2., no peer can hold more than two proxies. *See* PARLIAMENT.

PRUD'HO'MME. (Lat. homo prudens.) In France, during the middle ages, municipal tribunals composed of citizens exercising a sort of conciliatory or equitable jurisdiction, as arbiters of disputes, inspectors of police, &c., were termed councils of *prud'hommes.* In 1806, a court of this denomination was re-established at Lyons by a law of Napoleon; its principal office is the decision of disputes between masters and workmen in the silk manufacture.

PRU'NING. The art of cutting off parts of plants, and more especially of trees and shrubs, with a view to strengthening those which remain, or of bringing the tree or plant into particular forms, calculated to increase particular products. Pruning therefore varies according to the kind of plant or tree to be pruned, and according to the object in view. In the case of forest trees, the general object of pruning is to increase the quantity of timber in the trunk by diminishing the side branches, commencing at the lower part of the tree when it is quite young, and gradually advancing upwards as the tree increases in growth. In the case of hedges, the object is to produce a dense mass from the ground upwards, which is effected by shortening the side branches. In the case of pruning trees which are cultivated for the sake of their fruit or blossoms, the object is to thin out the branches so as to admit the light and air more freely to their leaves and blossoms, and to concentrate and increase the nourishment to the branches which remain. In the case of trees, or shrubs cultivated for the beauty of their shapes, whether natural or artificial, the object of pruning is to deprive the trees or shrubs of all those branches which deviate from or interfere with the natural shape, or with the form which is intended to be produced by art. In pruning with a view to produce fruit, it is necessary to know on what description of branches and buds the fruit is produced In some trees, as in the peach, it is generally produced on the wood of the preceding year; in others, as in the apple and pear, it is generally produced on wood of two years' growth; and in the vine it is produced on shoots of the current year. The general effect of pruning on plants is to increase their longevity; since the tendency of all vegetables is to ex-

haust themselves, and, consequently, to shorten their duration, by the production of seeds. In the operation of pruning, the shoots are cut off close to the buds, or at a distance from them not greater than the diameter of the branch to be cut off; because, without the near proximity of a bud, the wounds will not heal over. In shoots which produce their buds alternately, the cut is made at the back of the bud, sloping from it, so as that it may be readily covered by bark in the same or in the following year. This is readily done with a pruning knife, by a slanting cut, made at an angle of 45° with the direction of the branch; but, in the case of branches where the buds are produced opposite each other, either one bud must be sacrificed, or the branch must be cut off at right angles to its line of direction; and this is more conveniently done by the pruning shears. The operation of pruning may in many cases be superseded by rubbing off, or pinching out, the leaf-buds, so as to prevent superfluous shoots from being produced.

PRU'NING KNIFE. A knife the blade of which has a straight edge, formed of well tempered steel, and of no great breadth, with a narrow point, in order that it may be more readily introduced among crowded branches. Formerly, pruning knives were hooked at the point; but the cuts made by such knives had a tendency to crush the shoot, and leave a rough section, more readily injured by the air and water, and less likely to be speedily healed over. Such knives, when of a large size, were called pruning hooks.

PRU'NING SHEARS. Shears in which one of the blades moves on a pivot which works in an oblong opening, instead of a circular one, by which means a draw cut is produced similar to that effected by a knife, instead of the crushing cut produced by common shears, which fractures the section left on the branch, and renders it liable to become diseased or to decay, instead of being covered over with fresh bark. Pruning shears are particularly adapted for cutting spiny or prickly shrubs, such as the different species of thorns, gooseberries, or roses.

PRURI'GO. (Lat. prurio, *I itch.*) An itching of the skin with the eruption of small pimples. The term is also medically applied to irritation of various parts of the body from other causes, as from vermin, worms, &c.

PRU'SSIAN BLUE. This beautiful dark blue pigment was accidentally discovered in 1710 by Diesbach, a chemist of Berlin. The process for its preparation was first published in the *Philosophical Transactions* for 1724, by Dr. Woodward. It is made by adding solution of *ferrocyanuret of potassium* to persulphate of iron. The ferrocyanuret of potassium is prepared by gently igniting carbonate of potassa with animal matters, such as horns, hoofs, or dried blood, in iron vessels, by which cyanuret of potassium and some cyanuret of iron are formed; the soluble parts are then washed out with water, and sulphate of iron added until the Prussian blue which is formed ceases to be decomposed by the free potassa contained in the solution; the ferrocyanuret of potassium is then set to crystallize, and separated by repeated crystallization from sulphate of potassa. It is thus obtained in truncated octoedral crystals of a yellow colour, commonly called *Prussiate of potash*. It is much used as a test of the presence of metals, and especially of iron, the peroxide of which it throws down from its solutions in the state of Prussian blue. This compound has generally been considered as a ferrocyanate of the peroxide of iron; but, according to Berzelius, it is a double cyanuret; that is, a ferrocyanuret of the sesquicyanuret of iron. Ferrocyanuret of potassium (prussiate of potash) is composed of 2 atoms of cyanuret of potassium $(66 \times 2) = 132$, and 1 atom of cyanuret of iron $(28 + 26) = 54$, and has, therefore, the equivalent $(132 + 54) = 186$.

PRU'SSIC ACID. The composition and chemical characters of this acid are given under the head of *hydrocyanic acid.* Prussic acid is frequently used medicinally as a powerful sedative and anti-irritant, especially to allay cough in phthysis, and to mitigate the spasmodic action in whooping-cough; but from its poisonous nature it requires to be employed with much caution. The antidotes for prussic acid, where it has been taken as a poison, are solution of chlorine, by which it is chemically decomposed; and ammonia, which combines with it, and acts as a stimulant.

PRY'TANES. (Gr. πρυτάνεις.) The Athenian senate consisted of 500 persons, elected fifty from each of the ten tribes; each of these fifties took it by turn to preside with the title of Prytanes, having one tenth of the year assigned to it; or, more accurately speaking, 34 days were allotted to each of the first four tribes, and 35 to the last six; the Attic year consisting of 354 days. Each fifty was again subdivided into five bodies of ten, which, when prytanes, took it by turns to perform the duties of prohedri (προεδροι), seven days being allotted each. From these prohedri, again, was chosen by lot an epistates (επιστατης) or president, whose office lasted one day.

PSALM. (Gr. ψαλμος, from ψαλλω, *I sing.*) A sacred song or hymn, originally accompanied with music. The book of Psalms is called, in the Hebrew, *Thehillim* (*praises*), in conformity with the general object of the collection. It seems to have been an article of faith, with most of the early fathers, that the Psalms were all of them composed by David; a strange notion, which the internal evidence of several immediately refutes. The Jews divide them into 5 books, ending with the 40th, 71st, 88th, 105th, and last, respectively. They, as well as all Christians, retain the number 150; but the divisions have varied. There is an apocryphal 151st added in some Greek versions. The 119th and following psalms to the 134th, called by some "gradual psalms," or "psalms of the stairs," a term of which various explanations have been given, are thought by Calmet and others to have been composed on the occasion of the deliverance from Babylon; possibly by Esdras, who is considered as the first collector of the Psalms; but they were at least partially used before, as early as the reign of Hezekiah.

PSA'LMODY. A general term applied to the whole subject of psalm-singing, &c.

PSA'LTER. A book of devotion containing the psalms. See *Palmer's Origines Liturgicæ*, vol. i. p. 207.

PSALTE'RIUM. (Lat. *a psalter or psalm-book.*) The name of the manyplies or third cavity of the complex stomach of the ruminant quadrupeds, so called because it is occupied by numerous broad folds of membrane resembling the leaves of a book.

PSA'LTERY. A stringed instrument in use among the ancient Jews, by whom it was called *nablum* (which see). It resembled, according to Burney, partly the lyre and partly the harp.

PSE'PHOI. (Gr.) A general name given to several things made use of by the Greeks in giving their suffrages, and in their computations, as small stones, shells, beans, &c. They were synonymous with the *calculi* and *tabellæ* of the Romans, which see.

PSEUDEPI'GRAPHY. (Gr. ψευδης, *false;* and επιγραφή, *inscription.*) The ascription of false names of authors to works. This was carried to a great extent among the Christians of the fourth and following centuries. Thus, the verses known by the name of Sibylline are evident Christian forgeries; and it is extremely difficult to distinguish the spurious works of the Fathers from the true. (See Gieseler, *Text-book of Eccl. Hist.*, 1st period, chap. 3. sec. 52. for a good section on Christian pseudepigraphy; *Fabricii Codex Pseudepigraphus;* Barbier, *Dict. des Ouvrages Anonymes et Pseudonymes*, contains a notice of most works falsely ascribed to their alleged authors in the French language.)

PSEU'DOBLEPSIS. (Gr. ψευδης, and βλεψις, *sight.*) There are various forms of false vision, some apparently dependent upon nervous irritation, others upon organic derangement Specks, network, colours, and imaginary bodies floating or dancing before the eyes, distorted vision, double vision, are among the most common modifications of this complaint. They occur in plethoric as well as in debilitated habits, and are the consequence occasionally of intense study, of weakening evacuations, of debauchery, of hysteria, and of hypochondriasis; the treatment, therefore, which is required is very various. Attention to the stomach and bowels, local bleeding, camphor, ether, and other nervine stimulants, change of scene and occupation, varied exercise, are among the efficient remedies. A very alarming case of double vision, with coloured circles in rapid motion dancing before the eyes, of two years' continuance, and brought on by too intense application of study, gave way to cupping and to a journey to the Highlands.

PSEU'DO BULB. In Botany, an enlarged aerial stem, resembling a tuber, from which it scarcely differs, except in being formed above ground, in the epidermis, being often extremely hard, and in retaining upon its surface the scars of leaves that it once bore.

PSEUDODIP'TERAL. (Gr. ψευδης, *false,* δις, *twice,* and πτερον, *a wing.*) In Architecture, a term denoting a building or temple wherein the distance from each side of the cell to the columns on the flanks is equal to two intercolumniations; the intermediate range of columns which would stand between the outer range and the cell being omitted.

PSEUDOISODO'MUM. (Gr. ψευδης, ισος, *equal,* and δομος, *a house.*) In Ancient Architecture, a species of masonry in which the height, thickness, and length of the courses are different. *See* ISODOMUM.

PSEU'DOPODS, *Pseudopoda.* (Gr. ψευδης, and πους, *foot.*) A name applied to a tribe of Polygastric Infusories, including those in which the body, by various contractions and changes of form, produces pediform processes.

PSEUDOSCO'RPIONS, *Pseudo-scorpiones.* A family of Arachnidans, including those with an oblong body divided into several segments, with two or four eyes, and six or eight legs, as the book-crabs (*Chelifer*).

PSEUDO'THYRON. (Gr. ψευδης, and θυρα, *a door.*) In Architecture, a false door.

PSI'TTACINES, *Psittacini.* (Parrot tribe) The name of a tribe of Scansorial birds, of which the genus *Psittacus* is the type.

PSO'AS MUSCLE. (Gr. ψοαι, *the loins.*) A large muscle upon the fore part and sides of the lumbar vertebræ. It bends the thigh forwards, and assists in turning it outwards.

PSO'PHIA. (Gr. ψοφεω, *I make a noise.*) A subgenus of storks, having a shorter bill than the rest, with the head and neck covered only with a kind of down, and the circumference of the eye naked. They frequent wooded regions, and subsist on grains and fruits. The best known species (*Psophia crepitans*) is a native of South America, and is remarkable for the ambiguous sound which it emits from time to time, and whence its specific name is derived. This bird is easily tamed by the Spanish settlers in South America, and is even taught by them to guide and defend the common poultry from the rapacious birds, as a shepherd's dog guards his sheep from the wolves.

PSO'RA. (Gr.) The itch. *See* ITCH.

PSORIA'SIS. A rough scaly state of cuticle, sometimes continuous and sometimes in patches, generally accompanied by chaps or fissures.

PSY'CHE. (Gr.) In Mythology, a nymph whom Cupid married, after she had been persecuted by Venus. The word signifies the soul, of which Psyche was considered the personification. This beautiful allegory is first known to us by the romance of Apuleius: but it is presumed to be of much earlier origin from its occurrence in relics of art. Lafontaine made it the subject of a pastoral, and Mrs. Tighe recently of a poem.
